---

JANUARY TO DECEMBER, 1915

## INDEX TO AUTHORS

- Alpers, William C.,  
A. Ph. A., History Second Decade, 3  
Christmas Greetings From President A. Ph.  
A., 1181  
Digitalis, Remarks on, 715  
Fields and Woods in June, 739  
Plant, Albert, A Tribute to, 861  
Qualification Requirements for Teachers in  
Colleges of Pharmacy, 1230  
The Merits of Pharmacy, 1198  
The President's Greetings, 1982  
Year Book A. Ph. A., 1352
- Apple, F. M.,  
Confectionery and Cough Drops, Display-  
ing, 309  
Prescriptions, What Constitutes Good Ser-  
vice, 152  
The Circulating Library as a Side Line, 1313
- Amy, H. V.,  
Color Standards and Cudbear, 1291  
Quizzes, Tests and Examinations, 1233
- Baker, W. E.,  
Drug Absorption, Some Factors in, 143
- Ballard, C. W.,  
Cinchona, Microscopy of Barks and Adulter-  
ants, 28  
Notes on the History of an American Can-  
nabis, 1299
- Barton, Wilfred M.,  
Medicine and Pharmacy, Relation Between,  
571
- Beal, J. H.,  
Food and Drug Acts, the Variation Clause  
of, 628  
Pharmacy Legislation, Standardization of,  
307  
Proprietary Medicines, Chairman Commis-  
sion of, 1148  
State Anti-Narcotic Law, The N. A. R. D.  
Draft for a, 627
- Becker, Lewis A.,  
British Pharmacopoeia, Some Observations  
on P. C., 912
- Bergen, E.,  
Wages, Paying More Than, 182
- Bernier, George M., Jr.,  
A Model, 370
- Bernier, George M.,  
Homeopathic Pharmacopoeia of the U. S.,  
298  
The Pharmacopoeia and Materia Medica of the  
U. S., 729  
United States Pharmacopoeial Commission  
Report of Committee on Revision, 1279
- Brown, H. B.,  
P. C. Code, Changes of, 912
- Brown, Arthur F.,  
Federal Food Medicine  
and Drug Act, 1938
- Brown, Walter M.,  
Facts and Figures, 190
- Brown, J. T.,  
General Principles, A series
- Brown, C. H.,  
Government Regulation of Pharmaceutical  
Education, 110
- Brown, H. W.,  
A new method of examination of candidates for  
the diploma, 1104
- Brown, H. L.,  
Glycerin, Preparation of, 117
- Brown, H. W.,  
Chlorine Test, Method Determination of  
Residual Chlorine, 871
- Brown, Geo. F.,  
Pharmaceutical Education, A Plea for the  
Revival of, 198
- Brown, Harold N.,  
Advertising Methods, 128
- Caddwell, H. A.,  
Infant Stramonium Linnæ, Analysis of,  
602
- Campbell, Andrew,  
Oil, Hydrocrated, 675
- Chase, Charles S.,  
Approved Methods of Physiological Stand-  
ardization of Drugs, 1289
- Chase, Walter M.,  
Prescription Prices In Detroit, 1357
- Clayton, Chester J.,  
Should the Retail Druggist Manufacture or  
Buy His Preparations, 500
- Clover, A. M.,  
Heroin Hydrochloride and Diacetyl-Mor-  
phine Hydrochloride, Assay and Composi-  
tion, 291  
Hydrogen Peroxide, Increased Acidity on  
Standing, 1108
- Cook, E. Fullerton,  
Current Review of Journals, 749  
Modern Business Methods for Pharmacy,  
953  
Modern Drug Store Merchandising, 339
- Cooper, Zada M.,  
Some Thoughts for Teachers, 789  
The Women's Section and Women Pharma-  
cists, 541
- Cousins, W. H.,  
The Price of Success, 515
- Craig, Hugh,  
The N. A. R. D. Model State Antinarcotic  
Law, 1128
- Day, William B.,  
Army Hospital Corps, 113  
Lectures and Laboratory Practice, Benefit  
to Students of, 37  
Report of General Secretary, 1919
- Dewey, Albert H.,  
A College of Pharmacy Prescription Room,  
811  
Relation of Pharmacy to Medicine, 231
- Diel, C. Lewis,  
Report Committee National Formulary, 271
- Dimmitt, Addison,  
Advertising the Prescription Department,  
1196
- Dimmock, A. E.,  
Determination of Glucose in Urine, 51
- Diner, Jacob,  
Pharmaceutical Education or the Education  
of the Pharmacist, Which? 465  
Prescription Department, How Would You  
Advertise? 159
- Dodge, Francis D.,  
Balsam of Peru, Assay of, 1222
- Dohme, A. R. L.,  
Cooperation of Science and Industry, 1278,  
1195
- Duncan, C. A.,  
Abstracts From Journal A. Ph. A., 859
- Dunn, Charles Wesley,  
Narcotic Legislation, Uniform State, 761
- Eberle, E. G.,  
See Editorials
- Edwards, C. W.,  
Twilight Sleep, 767
- Elford, Frank R.,  
Contributions of Chemist to Manufacturer  
Pharmaceutical Products, 756  
Drug Laws, Enforcement of,  
Pharmaceutical Education, 161
- Errell, Edith H.,  
Chairman's Address, Scientific Section, 1120  
Estimation of Ataxyl, 1168  
Glucosides, Separation of, 609  
Mercuric Nitrate and Acetate, 188  
Stability of Preparations Containing Yel-  
low Phosphorus, 1109  
Yellow Phosphorus, Emulsion, 451
- Fairbank, J. W.,  
Current Review Pharmaceutical Journals,  
87  
Overstocking in the Retail Drug Business,  
1188  
State Narcotic Legislation, 578  
Statement to Committee on Patents and  
Trade Marks, 1119  
Sugar of Milk, Quality of Commercial, 944  
The Prescription of Life, 619

- Fantus, Bernard,  
Can the Pharmacopoeia and National Formulary Be Made Popular With Physicians? 349
- Fuller's Earth, Adsorptive and Antidotal Value of, 826
- What Instruction Ought Medical Colleges Give in Pharmacology and Therapeutics? 379
- Fischelis, R. P.,  
A Plan for a More Serviceable A. Ph. A. Journal, 614  
Education, Providing Needed, 1235  
Pharmacists and the Right Kind of Apprentices, 165
- Forbing, John W.,  
Burette, An Improved Form of, 934  
Salicylic Acid, Derivatives of, 118
- Freericks, F. H.,  
Chairman's Report Voluntary Conference Modern Pharmacy Laws, 1431  
Education and Legislation, Address Section on, 1207  
Statement re Committee Patents and Trademarks, 1419  
The Harrison Act, 397
- French, Harry B.,  
Drug Importations, Further Facts About, 511  
The War and Drug Importations, 239
- Fried, Leo H.,  
Iodine Ointment, Data and Method of Assay, 621
- Gane, E. H.,  
Petrolatum, Russian and American Liquid, 792
- Gathercoal, E. N.,  
Plea for an Up-to-date Year Book, 1504  
Rhamnus Barks, The Pharmacognosy of Medicinal, 65, 193, 360  
Teaching Materia Medica in Medical Schools, 1324
- Graber, Howard T.,  
Comparison Pharmacopoeial Methods, Digestive Ferments and Animal Products, 686
- Grantham, R. I.,  
Calomel, Estimation of, 441
- Gray, William,  
Re-distilled Water Versus Sterilized Distilled Water, 816  
Sugar in Urine, Estimation of Bang's Method, 740
- Greyer, Julius,  
Mineral Waters, Origin, etc., 488
- Groat, H. S.,  
Cold Creams, The Chemistry of, 169  
Perfumes, Artificial, 175
- Hackman, Charles A.,  
Fats and Oils, Estimation, 994
- Hall, William A.,  
Corrosive Sublimate Poisoning, New Antidote for, 183
- Hamilton, H. C.,  
Cannabis Sativa, 448
- Hance, Edward H.,  
Obituary, 128
- Harris, R. T.,  
Heroin Hydrochloride and Diacetyl-Morphine Hydrochloride, 291
- Hensel, Samuel T.,  
Additional Data Concerning Preparation Milk of Magnesia, 1361  
Resins, Freshly Precipitated in Aqueous Medium, 371
- Hepburn, Joseph Samuel  
Enzymes, The Behavior of at Low Temperature, 682
- Hill, Reuben L.,  
Colloidal Iron in Determination of Lactose in Milk, 744
- Hilton, S. L.,  
Petrolatum, Liquid, 993
- Holmes, Ralph C.,  
Cineol in Oil of Eucalyptus, Estimation of, 351  
A Safety Check Valve Vacuum Pump, 1227
- Hoover, Charles P.,  
Water Purification at Columbus, Ohio, 228
- Hozer, W. A.,  
Letter to Commercial Section, 1191
- Hostmann, Jeannot,  
Galenicals, Assaying, 324  
Miscibility of Ichthyol, 1490
- Howell, E. V.,  
Insecticides, Disinfectants, etc., Opportunity to Handle, 312
- Hynson, H. P.,  
Chairman Committee American Institute Prescripionists Report, 1171  
House of Delegates A. Ph. A., in Regard to Its Betterment, 524  
The House of Delegates, 844
- Jones, Ernest R.,  
Cold Creams, Greasy, 768  
Zinc Oxide Ointment, A Needed Change in, 283
- Jones, H. W.,  
Estimation of Morphine in Pills and Tablets, 1477  
Hydrastis and Fluidextract, Assay of, 106
- Jordan, C. B.,  
Pharmacy, Plea for Higher Standard to Enter, 51
- Kilmer, Fred B.,  
Absorbent Cotton and Absorbent Gauze, Standards for, 1228  
The British Pharmacopoeia From British Point of View, 900
- Kimble, J. E.,  
Magnesium Phosphate in Poppy Capsules, 623
- Kimmich, E.,  
Galenicals, Deterioration of, 178
- Kenaston, Mrs. Hampton Ray,  
Ipecacuanha, Botanical Source and Medicinal Value of, 938
- Knabe, Gustavus A.,  
Obituary, 130
- Kuever, R. A.,  
Report as Secretary Section Education and Legislation, 1310
- Kremers, Edward,  
Pharmacy, Study of the History of, By Students in Pharmacy at American Institutions of Learning, 482
- Lackenbach, Fred I.,  
Biologic Assay and Bacteriology, 1281
- Lascoff, J. Leon,  
Soft Capsules, Apparatus for Filling, 1184

## INDEX TO SUBJECTS

### A

- Absorption  
some factors in drug, W. F. Baker, 443
- Abstracts  
from Journal A. Ph. A. pertaining to prac-  
tical pharmacy, C. A. Duncan, 850
- should be furnished with papers, 1237
- Acetone  
determination of in urine, 1489
- Acid  
salicylic, derivatives, J. W. Forbing, 118
- salicylic in acetylsalicylic acid; 646
- sulphurous, determination of, 1403
- uric, origin of, 837
- Actinomyces Myricarum  
the cause of myrica comptonia tubercles,  
Heber W. Youngken, 1095
- Adulterations  
of drugs and chemicals, 225
- Agar-Agar  
on the preparation of flake, F. W. Nitardy,  
173
- Address  
of welcome to A. Ph. A., Sylvester McAtee,  
1015
- Chairman F. T. Green, San Francisco meet-  
ing, 1015
- chairman section education and legisla-  
tion, 20
- chairman scientific section, H. Engelhardt,  
1120
- chairman section practical pharmacy and  
dispensing, 1168
- chairman section commercial interests, 1203
- chairman section on education and legisla-  
tion, 1207
- President C. A. Mayo, 1017
- synopsis President Wulling, A. C. P. F., 1094
- Advertising  
how would you advertise prescription de-  
partment, Jacob Diner, 50
- methods, Harold N. Bruun, 318
- the prescription department, Addison Dim-  
mitt, 1196
- Alcohol, denatured  
permissible in collodion, 1529
- Alcohol, methyl, label for, 1317, 1398
- Alkaloids  
colloidal state of, 1346
- examination of calycanthus floridus for, E.  
R. Miller and H. W. Brooks, 433
- gelsemium, third alkaloid from, A. E.  
Stevenson and L. E. Sayre, 60
- Allspice  
structural variation of, William Mansfield,  
62
- Aluminum  
chloride, 632
- sulphate, 632
- Ameba, definition, 1442
- American Pharmaceutical Association  
aims and purposes, C. A. Mayo, 1501
- property of in Lloyd Library, 1374
- sessions, San Francisco meeting, 1015, 1039,  
1069
- Ampuls, Herman H. North, 567
- filling, 810
- Analysis  
cigarettes, cigars, tobacco and use of  
Lloyd's Regent in determination of  
nicotine, Azor Thurston, 435
- datura stramonium, L. E. Sayre and H. V.  
Caldwell, 602
- see also determination, estimation and  
assay
- Antibodies and Antigens, 1445
- Antidote  
belladonna poisoning, 237
- corrosive sublimate poisoning, William A.  
Hall, 183
- Antimony  
oxide, 633
- sulphide, purified, 633
- Antitoxins, 302, 1440
- Apparatus for filling soft capsules, J. Leon  
Lascoff, 1184
- Apprentices  
right kind and pharmacists, R. P. Fischelis,  
165
- Apprenticeship in America Fifty Years Ago,  
J. U. Lloyd, 1333
- Appropriations  
army budget for 1915, 137, 1246
- hospital corps, W. B. Day, 113
- Army, H. V.,  
President A. C. P. F., 1112
- Arsenic  
A biological test for, Albert Schneider, 1307
- Assay  
alkaloidal, possible source of error, P. A.  
W. Self, 695
- balsam of Peru, Francis D. Dodge and  
Alfred E. Sherndal, 1222; see also 1496
- biologic and bacteriology, Fred I. Lacken-  
bach, 1281
- digitalis, end-point, L. W. Rowe, 108
- elixir lactated pepsin, 219
- galenicals and apparatus needed, Jeannot  
Hostmann, 324
- glycerin, 75 and 78
- hydrastis, H. W. Jones, 106
- heroin hydrochloride, R. T. Harris and A.  
M. Clover, 291
- iodine ointment, Leo H. Fried, 621
- opium, 85 and 92
- pharmaceutical preparations, 765
- pharmacodynamic method preliminary note,  
Paul S. Pittenger, and Charles E. Van-  
derkleed, 427
- sempervirine, 1458

report of invested funds, 897, 1254  
 report nominating, 1041  
 report of special on Year Book and National Formulary, 1375  
 report of, on time and place, 1075  
 report, William Procter, Jr., monument fund, 1055  
 resolutions on, 1039  
 syllabus committee membership of, 639, 1516  
 syllabus committee report, 1056, 1516  
 transportation announcement, 411  
 transportation drugs by mail, 1408  
 transportation drugs by mail, enlarged committee, 1409  
 unofficial standards, report of, 632, 781, 1378  
 committee Year Book and National Formulary, 1375  
 weights and measures, 1046  
 see also reports and addresses  
 Condurango, examination of, 1329  
**Conference**  
 drafting pharmacy law report, 1431  
 drug trades, report of, 1222  
 members voluntary of, for drafting pharmacy laws, 1431  
 pharmaceutical faculties, annual meeting, 1091  
 College and Society, 416, 553, 652, 769, 872, 1006, 1143, 1519  
 College of Pharmacy  
 inherent possibilities for rendering maximum efficient service, Frederick J. Wulling, 575  
 Cold Creams  
 absorbent, 158  
 greasy, E. J. Jones, 708  
 the chemistry of, H. S. Groat, 169  
 Condurango, 751  
 Confectionery  
 displaying, F. M. Apple, 309  
 Conference National Drug Trades, 122  
 Conference Members of Voluntary Modern Pharmacy Law, 641  
**Congresses**  
 International Versus the European War, Joseph P. Remington, 563  
 Conium, 752  
 Constitution, Amendments of, 1041, 1248  
 Convallaria, 753  
**Co-operation**  
 a necessity, Joseph P. Remington, 1237  
 of science and industry, A. R. L. Dohme, 1105  
 Copper Sulphate, 754  
 Corydalis, 1511  
 Cotton and Gauze  
 absorbent standards for, Fred B. Kilmer, 1228  
 Cotton Root Bark, 1132  
 Coumarin, 175  
**Council**  
 committees of, 1273, 1376  
 committee report on House of Delegates, 1252  
 letters, 137, 255, 659, 778, 880, 1011, 1271  
 members, 1145, 1271  
 motions of synopsis, 1246  
 report of secretary, 1246  
 proceedings, San Francisco meeting, 1245, 1374  
 Crocus, 753  
 Cypridium, 754

**D**

**Data**  
 autobiographical to be furnished Historical Section by members, 1375  
**Datura Stramonium**  
 analysis, L. E. Sayre, and H. V. Caldwell, 602  
 Dawson, John H.  
 elected local secretary, A. Ph. A., 882  
 Degrees, Pharmaceutical, 1410  
**Delegates**  
 addresses before A. Ph. A., San Francisco meeting, 1030  
**Detection**  
 arachis oil in olive oil, 1495  
**Determination**  
 acetone in urine, 1489

carbon dioxide in baking powder, H. W. Brubaker, 817  
 glucose in urine, A. F. Dimmock, 54  
 lactose in milk with colloidal iron, R. L. Hill, 744  
 of sulphurous acid, 1403  
 see also assay, analysis, estimation  
 Diehl, C. Lewis, honorarium voted, 1377  
**Digestive Ferments**  
 and animal products comparison, pharmacopoeial methods, Howard T. Graber, 686  
**Digitalis**  
 end-point digitalis assay, L. W. Rowe, 108  
 pharmacodynamic assay, 427  
 remarks on, W. C. Alpers, 715  
**Directory**  
 local branches, VII (June)  
**Dispensaries**  
 monastic of middle ages, Leo R. A. Suppan, 383  
 Dohme, Charles E., 1000  
 Drug Stores, too many, 1190  
**Drug Business**  
 overstocking in, J. W. England, 1188  
**Drug Reform**  
 committee on, report, 1425  
**Drugs**  
 addicts, number and kind, M. I. Wilbert, 963  
 and the man, A. E. Bostwick, 915  
 cost before and since the war, 242  
 criticism of official descriptions, C. J. Zufall, 530  
 facts concerning importation, H. H. Rusby, 246  
 importations, further facts, Harry B. French, 511  
 moisture lost in, 527  
 inferior, list of, 225  
 the pharmacy of useful, M. I. Wilbert, 823  
 quality of, 975  
 some factors in absorption in frogs, W. F. Baker, 443  
 transportation of by mail, 1408  
 variation in strength of, 1306  
 war and drug importations, Harry B. French, 239  
 see also name of drug  
 Dyestuff situation in U. S., T. M. Norton, 731

**E**

**Earth, Kambara**  
 its use and reagent for cod liver oil, 1405  
**Editor**  
 election of, 779  
**Editorials**  
 advertising, E. G. Eberle, 840  
 Christmas wish, E. G. Eberle, 1407  
 commercial pharmacy, E. C. Marshall, 327  
 compound digestive elixir, E. G. Eberle, 1351  
 co-operation, E. G. Eberle, 1084  
 conference, Pan-American financial, E. G. Eberle, 727  
 difference of opinion stimulates progress, E. G. Eberle, 1481  
 diversification and specialization, E. G. Eberle, 829  
 emergency revenue law and plans to protect the American Manufacturer, E. G. Eberle, 1347  
 Greetings, William C. Alpers, 1082  
 Harrison law decision, E. G. Eberle, 1483  
 home of Journal A. Ph. A., E. G. Eberle, 1480  
 "I Will," E. G. Eberle, 958  
 law, Harrison, an important ruling on, E. G. Eberle, 725  
 looking forward, E. G. Eberle, 958  
 National Insurance Acts of Great Britain, E. C. Marshall, 328  
 New-year greeting, E. G. Eberle, 1407  
 new taxes, E. G. Eberle, 1220  
 not more legislation—better legislation, E. G. Eberle, 725  
 papers, E. G. Eberle, 961  
 Patience and "Pearson's," E. C. Marshall, 55  
 pellagra, a social or medical problem? E. G. Eberle, 1482  
 pharmacy and the public, E. G. Eberle, 609

- pharmacists, in aid of Belgian, E. G. Eberle, 727  
 price maintenance, E. G. Eberle, 1218  
 professional vs. "commercial pharmacy," E. G. Eberle, 813  
 progressive work of A. Ph. A., E. G. Eberle, 838  
 San Francisco meeting, E. G. Eberle, 608, 1083  
 State Association meeting, E. G. Eberle, 610  
 State narcotic legislation, J. W. England, 518  
 the dye industry, E. G. Eberle, 722

## HISTORY OF THE AMERICAN PHARMACEUTICAL ASSOCIATION. SECOND DECADE.

WILLIAM C. ALPERS, SC. D.

(Continued from December Number.)

When the Association convened for its sixteenth meeting in 1867 at Philadelphia, President Milhau was unable to attend owing to ill health and the First Vice-President, Robert J. Brown, therefore presided the first half of the meeting. There were one hundred and thirty-four members present, the first time that one hundred was exceeded. One of the members of the Association who had died during the preceeding year, was Henry F. Fish, of Connecticut, who had been present at the first annual meeting, who came from his interest in the new Association without having been delegated by any local association or college. He was Third Vice-President in 1855.

The President's address was note-worthy for its many recommendations, nearly all of them affecting the usefulness of the Association and methods for expediting transaction of business. These recommendations were afterwards taken up and caused much debate and exchange of opinion, in which old and new members of the Association participated. At the close of his address, Mr. Milhau made these pertinent remarks:

"I would address you according to my convictions on the true plan, to use the words of the Constitution, 'Of improving the science and art of pharmacy, of regulating the system of apprenticeship, and of suppressing empiricism' with any degree of success—and that is by professional instruction. It will require the whole influence of every member to further the plan proposed or a better one. It will take a long time and require hard work. We must commence by organizing our forces. It would be necessary to appoint 'a central committee on laws and colleges,' and all the members in each state should band themselves together and constitute 'sub-committees' for their respective states. The general committee should publish a full collection of all the existing state laws bearing on the subject, together with comments, followed by an account of kindred laws in Great Britain, especially those lately enacted. They will issue instructions as far as necessary, and drafts of the proposed laws for

the use of the sub-committees. Every member should, by explanation and by all proper arguments, endeavor to enlist the influence of every prominent citizen he can reach,—the state representatives, the ministers, the lawyers, the physicians, his customers, and the editors—so as to bring the legislature and executive of each state over to our views, and never cease, till we have obtained the requisite laws, and founded a college of pharmacy in each state. It was by such means that we succeeded in obtaining the drug law of 1848, when the country was much less prepared for such a step than now."

He also makes a plea for the official recognition of pharmaceutical colleges and hopes that the time will come soon when a diploma or certificate will be a *sine qua non*. Such a statement from a man who was generally supposed to be a representative of the business part of pharmacy and at such an early date deserves recognition.

Among the delegates there were two from Canada, and Mr. Stearns took occasion to welcome them and offered the following resolution:

*"Resolved*, That the American Pharmaceutical Association welcomes heartily the presence at this meeting of the delegates from the Montreal Chemists' Association—the first one credited to us from the Dominion of Canada."

The two delegates, Mr. Mercer and Mr. Edwards, replied in a happy and pleasing manner.

Among the new officers elected at this meeting, there were Edward Parrish of Philadelphia, for President; Albert E. Ebert of Chicago, one of the Vice-Presidents; and Dr. Frederick Hoffman of New York, Chairman of the Committee on the Progress of Pharmacy. This last election was certainly a high tribute paid to Dr. Hoffman, who had only joined the Association at that meeting.

The question of incorporation again caused a long debate in which all the leading men participated and it is remarkable how nearly every one opposed it. Mr. Procter says: "My own view is in opposition to such a course. I do not approve of it." Mr. Stearns says: "You could not get it if you wanted it." Mr. Bedford says: "My views are the same." Prof. Moore says: "I don't see any practical advantage in incorporation." No action was taken.

A long, and sometimes heated, debate took place when the second letter from the East River Medical Association was read with reference to the renewal of prescriptions. Those who are interested in the various views as to the proprietorship of prescriptions and the proper attitude of pharmacists to take, so as to do justice to physicians, as well as to the public should not fail to read these discussions which took up more than twelve pages in very small type and thoroly exhaust the subject. The matter was finally referred to a Committee of five, with Mr. Stearns as Chairman, who at a later session offered the following resolution, which was adopted by unanimous vote. While the question itself was not settled thereby, it is well worth while to reproduce this resolution, so as to show the opinion of the Association on this question forty years ago.

*"WHEREAS*, The East River Medical Association of New York, through its Secretary, has submitted a preamble and series of resolutions regarding the renewal of physicians' prescriptions without the authority for such renewals, for our consideration, and

*"WHEREAS*, The discussion of this important subject has called forth a free expression of opinion from our members; therefore be it

*"Resolved*, That the Association regard the pharmacist as the proper custodian and owner of the physician's prescriptions once dispensed.

*"Resolved*, That however desirous we may be to accede to the request of the East River Medical Association, the restriction of the pharmacist to a single dispensing of a prescription, without the written authority of the prescribing physician for its renewal is neither practical nor within the province of the Association. Nevertheless we regard the indiscriminate

renewal of prescriptions, especially when intended for the use of others than those for whom they were prescribed, as neither just to the physician nor to the patient, between whom we stand as conservators of the interests of both, and that such abuses should be discouraged by all proper means."

The recommendation of the President to have a committee appointed to collect formulas for un-official preparations, also brought out many diverging opinions, but finally such a committee was appointed. The question of a rather political nature that agitated this country ever since, was that of duties on drugs, and it seems that the members of the Association at that time were not impressed particularly with the value of high tariff, for "on motion of the Business Committee, it was resolved, that in the opinion of the Association the duties on drugs ought to be reduced."

Query 16, presented at the sixteenth meeting, namely, "How far is Pharmacy entitled to rank as a Profession, and what is its true position among the industrial pursuits?" had been left for general acceptance, but, not being answered, it was presented by the President for general discussion. In the course of these discussions the question of the name of "Pharmaca" and "Pharmacist" was again brought up and Mr. Parrish made the remark: "Now for these terms 'pharmacist,' etc., was it not I that read the first paper about it? I shall have to claim that invention. You will find it in the Proceedings of two years ago at Detroit—a paper proposing the general use of the term 'pharmacist'"; to which, however, the following retorts were made: Dr. Squibb said: "You can find it in Worcester's dictionary"; and Mr. Markoe said: "Webster has had it for many years."

In order to settle this claim of Mr. Parrish of the words "pharmacist," and "pharmaca," and "pharmacy," to indicate the place of business of the pharmacist, your historian has taken much pains in tracing these words, with this result: In Webster's Dictionary the word "Pharmacist" appears in the edition of 1865 for the first time, preceding edition of 1857 not having it. In Worcester's Dictionary it appears first in 1866. This shows that it was used in the United States before Mr. Parrish read his paper in 1866. In English literature it appears in Lord Bulwer Lytton's novel, "The Last Days of Pompeii," which was published in 1834. The quotation being, (part 1, pg. 11) "Unskilful pharmacists! pleasure and study are not elements to be thus mixed together." In none of these works does the word "pharmaca" appear, and the word "pharmacy" is defined as the science and art of preparing medicine. It will be seen therefore, that Mr. Parrish cannot claim priority to the word "pharmacist," but is entitled to the invention of "pharmaca" and the application of "pharmacy" to the place of business of the pharmacist.

The question whether pharmacy was a business or a profession was answered by most of them stating that it was neither, it was an art; claiming that the word "art" was more comprehensive, broader and more significant, than either of the others.

The question of a code of ethics was brought up by Mr. Maisch. A code of ethics was drafted at the preliminary meeting in 1851, which gave rise to the American Pharmaceutical Association. It was also printed in the first volume of the proceedings, but after that was omitted. Mr. Maisch asked the question

whether this code of ethics was still in force and whether new members in signing the Constitution also subscribed to this code. The matter was finally referred to a committee under the chairmanship of William J. Procter, Jr., to report at a later meeting. This committee reported that the original code of ethics was afterwards incorporated in the Constitution and that there seemed to be no necessity to continue it any longer. A motion by Mr. Allison that the code of ethics be considered as superseded by, and embodied in, Article 1 of the Constitution, was unanimously adopted.

The regret of President Milbau, that it was sometimes very difficult to obtain the proper information on the life and doings of deceased members, caused the Business Committee to bring forward the suggestion that the members of each state form a local committee to furnish the Executive Committee with proper information. It was also suggested that an obituary committee might be created. Later on another resolution bearing on this question was offered, namely:

*"Resolved, That a committee of five be appointed by the chair to solicit photographs of members of the Association to be kept in an album, to be on exhibition at our future meetings."*

It is to be regretted that the idea of making a card for every new member, on which all facts and details of his life, education, work and activities, inside and outside of the Association were to be recorded, was not established at this time. Such a cabinet of cards, embracing by this time about four to five thousand names, would be more than valuable material for the present or future historian, and would have the undisputed advantage of authenticity.

Dr. Hoffman called the attention of the Association to the fact that Professor Ehrenberg of Berlin, inventor of the microscope, was about to celebrate the fiftieth anniversary of his Doctorate, and that it would be proper for this Association to appoint a committee to prepare an address embodying the kind sentiments of the Association, to be sent to Dr. Ehrenberg on the occasion of his approaching jubilee. The Committee consisted of Dr. H. P. Procter and Mr. J. M. Maisch.

A number of honorary members, living in Europe, were appointed at this meeting, namely:

Daniel Hanbury	London, England
Henry Deane	London, England
A. E. De Meyer	Brussels, Belgium
Norbert Gille	Brussels, Belgium
Dr. E. A. Fluckiger	Berne, Switzerland
Dr. G. C. Witschein	Munich, Germany
Dr. Frederick Mohr	Bonn, Germany
Dr. Hermann Hager	Berlin, Germany
Dr. G. Dragendorff	Dorpat, Russia
Dr. Arthur Gesselmann	St. Petersburg, Russia
Mr. Robinet	Paris, France
Mr. Poilly	Paris, France

From the reports, the one on Progress of Pharmacy, written by C. Lewis Diehl, comprised one hundred and fifty seven pages, more than one-third of the whole book. In this report, as well as in nearly all others handed in at this meeting, the word "pharmacist" is continually used in place of "pharmaceutist," but the official reading of the Constitution still adheres to the old name. The most remarkable report of the year was the report of the Committee of Drug

Market, signed by Daniel C. Robbins. It seems that Mr. Robbins was somewhat displeased with the condition of Pharmacy in the United States, and this spirit of dissatisfaction and unfavorable criticism pops out more or less in all parts of the report.

The first part again reviews the different terms and compares the words "druggist, chemist, apothecary, pharmacist and pharmacist" coming to the conclusion that

"the two words, 'druggist and pharmacist,' will probably come into general use, the one as the most fitting term for all dealers in druggists' articles, and the other, as the only word, unless we invent some new one, that can include a knowledge of combinations of all kinds, chemicals, and what we call compatible combination, for the want of a more precise term, the first implying a knowledge of the laws of chemical affinity, and the last, a knowledge of those controlling forces which crude material substances exert over each other in determining combinations. A good chemist may not understand pharmacy, but an accomplished pharmacist must understand chemistry, but hence while we cannot define pharmacy as we can chemistry, we must accord it a superior position, from the fact that the greater includes the less."

After deploring the want of respect for most of the professions in the United States, he makes a strong plea:

"But we must remember that it is not good for us to be forever in the chamber of suffering or always attendant on death, no constitution can endure it and no pursuit can stand it; we *must* renovate ourselves, *must* fill our empty shelves; the apothecaries *must* go out anew into life and catch the beat of its pulse forever renewed, and fill themselves with all the light of the day, take a look at the ocean of life and feel the breath of its sea.

"What we most want is a just estimate of ourselves, of our resources, of our obligations; and the true policy of the druggist and pharmacist is, to make his pursuit or his profession as useful as possible in all ways. We do not want less range, but more education, more character, because in our pursuit, more than in any other, there is a demand for character in the individual, for quality in the article, and for a better standard of morals in trade."

Mr. Robbins then goes into a classification of drugs and chemicals and favors greatly the French method in preference to the German or the English. Then comes a long record of the imports and exports of drugs of the United States, which more or less are based on the wants of the wholesaler than the retailer. He regrets that it is almost impossible to get pure drugs of any kind, and becomes more severe when he speaks of secret remedies.

"It is generally conceded by our apothecaries that about one-half of all their sales, in amount to customers is derived from this source, and if it were possible to obtain reliable statistics of the per capita or total consumption of these compounds within the Union, the American people would wake, and put in chains a traffic that panders to many vices, that seldom hesitates to any imposture, and as a rule considers the deception of the public to be a legitimate business." And again he says, "The proprietor of a secret remedy should have no more right to protection under the law as applied to trade marks than the freebooter of the ocean has to protection under the flag which has been so long recognized as the mark of his trade, and of the poison bottle; but we want a law to confirm this. The secrecy of any medicinal preparation should be *prima facie* evidence of fraudulent intent."

The report closes with a complete list of importations, giving the quantity, value and duty and the revenue, and advocates the cancellation of all revenue laws and inspection of imports.

It can easily be understood that a report of this kind caused some discussion and gave rise to a great many remarks. While, in a general way, Mr. Robbins was supported by the older members of the Association it was yet thought that his language in some places was too strong and that his demand that all drug laws should be repealed could not be well supported by the entire Association.

It was pointed out to him that the desire to have drug laws gave rise to the formation of the Association, and that no other body of men in the United States had been more active in inducing Congress to enact these laws than the American Pharmaceutical Association. Now to demand that all these laws be repealed would be to annul the whole history of the Association, and even if some of the laws were bad or badly executed,—if some of those entrusted with their carrying out had proven to be dishonest, and turned them to selfish purposes,—it must yet be admitted that an enormous amount of good had been done by these laws and that the demand for their repeal would not be in harmony with the history of the Association. After a lengthy debate the matter was referred to a committee under the chairmanship of Mr. W. A. Gellatly, who later on brought in the following resolution, which was adopted:

*"Resolved, That in accepting the valuable and interesting report of the Committee on the Drug Market, this association does not endorse the portion referring to the utility of the law requiring the examination of foreign drugs before entry at the custom house (a law intimately connected with the origin of this body), believing that, however imperfect the law may be, its comparative fruitlessness has mainly arisen from the inability and unfitness of the agents appointed to execute its provisions."*

Another very interesting report was that of the Committee on Legislation, regulating the practice of pharmacy, consisting of the President and other officers of the Association.

The report comprised forty-one pages and gives a complete history of the various legislations in the States as enacted at that time. It also gives a history of the various colleges, of the Boards of Pharmacy and their method of examination and their appointments. It then touches the question of adulteration and poison law; illicit selling and handling of liquor in drug stores and gives a number of letters from representatives in Congress, judges, and other members of importance, with reference to this matter. It finally offered a resolution:

*"Resolved, That the President and ex-Presidents of this Association, attending this meeting, be appointed a committee to take into consideration,*

*"First, The propriety of drafting a law regulating the entire practice of pharmacy, to be presented to the legislatures of the different states and territories for their adoption, together with a memorial setting forth the duties of the profession to the public, and its actual and contemplated status;*

*"Second, The propriety of inviting the co-operation of the American Medical Association, and of the local Medical and Pharmaceutical Societies;*

*"And that the committee thus appointed be requested to report at a subsequent session."*

After some debate the resolution was adopted without the second clause. Later on a new committee on the same subject was appointed by the President consisting of William Wright, Jr., of New York; Frederick Stearns, Detroit; J. Faris Moore, Baltimore.

It seems that the Association missed one great chance of usefulness in not taking up this question in a broader and more general sense. It is well known that since those days the physicians have applied to the legislatures and Congress for laws helping them in their practice and strengthening their position in the community and in law. If the pharmacists in those days had also undertaken to make pharmacy legislation a national issue, many of the difficulties that later

on arose and a good deal of the indifference that was shown in later years in various states towards the working of the American Pharmaceutical Association could now have been avoided.

From the many papers of a scientific nature that were presented at this meeting, we will mention the paper on "*Commercial Hydrargyrum Cum Creta*," the first paper read in the Association by Joseph P. Remington. Mr. H. W. Lincoln read an interesting paper on the Coat of Arms of Pharmacists, called "*Opiferque Per Orbem Dicor*"—(And I am called a bringer of help throughout the world.)

A very interesting and exhaustive paper was that of Dr. E. R. Squibb on "Carbolic Acid," at that time a new and almost unknown article. It strikes us to-day in almost a humorous way to notice in the debate that one member praised carbolic acid as a great invention, as a solution of it had cleaned his dog of fleas, while another one claimed that he had used it in the same way and found it entirely useless. Other papers related to the practice of pharmacy, the prescribing and preparation of various drugs, syrups and elixirs. They all showed a deep interest taken in this work all over the country and present a valuable record of the history of various preparations.

Mr. Parrish in a paper on "The Means of Improvement for Young Pharmacists," who were prevented from attending college, lays down three rules which will give them ability to practice their profession.

"First. Observation—The cultivation of the senses of sight, touch, taste and smell is of prime importance to the pharmacist, as it is indeed to every dealer in merchandise.

"Second. Experiment—The little word 'try' conveys a lesson which every one should learn at the very outset of his course.

"Third. Reading—Blessed agencies are good books in every scheme of education. What wonderful facilities for improvement do these furnish in the present day, as compared with any previous period."

The proceedings of this meeting, comprising about five hundred pages, is one of the most interesting and instructive books of the series. The observant reader, however, cannot avoid two general impressions. The first, the tedious and somewhat clumsy way in which the business of this now national Association is conducted, and what an enormous amount of time is wasted in reproducing and reading of reports that were of no use to the members and other unnecessary formalities. That a change in the method should soon take place is evident. Another impression of a more serious nature is that, sooner or later, dissension or difference of opinion of serious kind, must break out in the Association. The time of construction and building-up had almost passed. So far there was nothing but friendliness and the desire to accommodate each other's opinions, but the time had come when it would be necessary to step out, speak sharply and define the proper and most important objects of the Association in clear and precise words. Mr. Parrish, in one of his remarks, says: "We started out on a different basis from that in which we now conduct the Association. The ideas of those who originated it were more restricted in regard to membership and many other questions." Through the whole proceedings there go the rumblings of a distant thunder, announcing the storm that was soon to come.

The seventeenth meeting of the Association was held at Chicago in 1869. President Parrish being absent, the First Vice-President, Ferris Bringhurst,

presided in the first half, and the newly elected President, Ezekiel H. Sargent, at the second half of the meeting. There were one hundred and thirty-one members present at this meeting and many new members were elected, among them George W. Kennedy of Pottsville, Penn., who afterwards, was for many years the Secretary of the Council.

The report of the Committee on Progress of Pharmacy was presented by Dr. Hoffman, and while in a general way it follows the method of the former reporters, it differs particularly in so far as Dr. Hoffman added at various points criticism and suggestions. The report contains one hundred and sixty pages, being more than one-third of the volume and shows an enormous amount of zeal and arduous work. At the end, the reporter makes a strong appeal to divide the work among several members, claiming that it was too much for one. The Business Committee, in consequence of this suggestion, proposed a resolution making the committee to consist of three members, to be elected every three years and to divide the subjects among them, also that the report of the committee, in addition to being printed in the proceedings, should be published separately in book form. No action was taken on this proposition.

At this meeting, the most detailed and interesting report on the Pharmacopœia, was presented by Dr. Squibb. It embraced forty-eight pages and was an exhaustive review of all the enormous investigations and examinations that had been made by members of the Association and others, tending to improve the methods of the Pharmacopœia. Many articles were recommended to be dropped and others to be added, and the report bristled with many suggestions to the physicians in reference to the method and way of conducting the revision. As the Association was not an incorporated body at that time, this report could not be presented as coming from the Association, which had no representation in the Convention, but it was ordered to be printed, and no doubt had an important influence with the members of the Revision Committee.

The report of the delegates from this Association to the third International Pharmaceutical Congress held at Vienna this year was presented by John Faber, the only one who attended this Convention. It treated to some extent on the same questions as the previous one, and the following resolution, being the third one is of particular value:

"That the superintendency of the medical profession is incompatible with the present status of pharmacy, the pharmacist of our modern times being beyond what he was a century ago, and that he is entitled to self government."

The 4th question, "Which way is to be adopted in order to obtain the most possible uniformity in the formulas and preparation of methods universally used?" was a continuation of the question about a universal codex. Faber reported as follows on this:

"A committee at Paris being engaged in working out a conspectus containing the different formulas of active remedies, with the view to have the Pharmacopœia of the different countries adopt uniform formulas in course of time; Congress expressed wishes for the committee to continue their labor in this direction, and to communicate with other pharmaceutical corporations about that subject."

The president in his annual address, which was a very able review of the activities and growth of the Association during the last year, dwelt at length

on the law to regulate the practice of pharmacy in the different States of the Union and to prevent the adulteration of drugs and medicines. He says:

"I cannot too highly commend this law to your serious consideration. Originally opposed to any attempt to prevent by legislation the evils which are so perceptible under our present unrestrained system, I have gradually arrived at the conclusion that the effort should now be made to exhibit to the legislatures of the several states such a law as, if it could be carried out, would be of immense advantage to the public, and would at once place pharmacy in its true position. The committee are aware of some imperfections in this draft, although it is the result of much careful study. I confess to grave doubts of its proving available in states in which our profession is not well organized."

His recommendation to fix the salary of the permanent secretary at \$400.00 and that of the treasurer at \$200.00 was later adopted. The Committee on Drug Market failed to bring in a report. The Business Committee recommended a number of changes of the Constitution, most of them relating again to the vexed question of raising funds. All the propositions and remarks relating to this subject were referred to the Committee for further consideration. This Committee prepared a lengthy report which was accepted and was to be acted upon at the following meeting in 1870. A great number of very interesting and instructive papers were presented at this meeting, most of them showing the great interest that the druggists of those days took in the investigation and determination of indigenous plants and articles of the Pharmacopœia in general. At this meeting also Mr. E. L. Milhau presented the first gelatin-coated pill and read an interesting paper on the same which was listened to with great interest and caused a very animated debate.

The two most important subjects, however, that made the meeting of 1869 a very remarkable one, were the reports of the Committee on the Law to regulate the practice of Pharmacy, and the expulsion of one of the most active and highly respected members of the Association.

Mr. W. Wright, Jr., as Chairman of the Committee charged with framing a law regulating the practice of pharmacy, reported verbally, that the Committee had attended to that duty and had the draft of the law printed in sufficient numbers to be distributed among the members present.

This draft of a proposed law which was printed in the proceedings is a very comprehensive and deep draft of a general pharmacy law. It is true there were some errors in it owing to the novelty of the work and the lack of experience of which the drafters of a later law of a similar kind could dispose, but it showed the deep thought and care that had been devoted to this work and would have been a good and serviceable model for the many State laws that were about to be formed and enacted in those days. It was hailed by some as the beginning of a new era, but it utterly failed of acceptance on account of the strong opposition of Dr. Squibb and a few of his friends who looked upon it from the standpoint of a physician, forgetting entirely that they were there as members of a Pharmaceutical Association and that the interests of the pharmacists should count first. At no other place in the proceedings, was the influence that Dr. Squibb exercised in those days at the Association, more pronounced than at this one, and while his remarks and his action do not detract at all from his reputation and great recognition as a pharmacologist, it is to be regretted that the older members of the Association did not muster courage

enough to oppose him in this one matter. It appears, to the historian, that the Association, in this one instance, missed its vocation. One of the greatest chances or possibilities to do good for American Pharmacy, was allowed to slip by, on account of this opposition and instead of framing a strong and forcible model-law for the various states, weak, compromise resolutions were passed.

These are some of Dr. Squibb's words with reference to this law:

"The pharmacist's vocation is entirely supplementary to the vocation of the physician; yet, here is a law that ignores physicians, and does not recognize the physician's diploma as entitling him to practice pharmacy, or to register as a pharmacist, while he is the only competent authority of the pharmacist and uses the medicines which the pharmacist prepares. I am willing to admit that the pharmacist knows more about preparing and compounding medicines than the physician does—not more than he should, but more than he does; that the pharmacist is the abler of the two in his profession, but that can never change the fact that the pharmacist is naturally and properly subordinate to the physician."

There were two ways open for the Association at that time, if they had understood the importance of the subject before them. They should either have come out boldly in direct opposition to the physicians, claiming that theirs is a profession of equal value and equal importance and that they were ready to deny and fight the assumed superiority of the medical profession or they should have made a strong and honest attempt to work in harmony with the physicians, who at that time were also framing new laws for their profession, and thereby make this harmony of the two professions one of the fundamentals of all new laws relating to medicine and pharmacy. The first standpoint was advocated by a number of members present at this meeting and from their remarks there can be no doubt that the animosity between pharmacists and physicians was much stronger and more pointed in those days than at any other time. It would have provoked a serious fight between the two professions, which however, would have resulted in the end in mutual respect and friendship.

Another way would have been to meet the physicians as friends and fellows. It is true many of them would have laughed at such an idea of recognizing a pharmacist as their equal, but those of better education and understanding, would have accepted the hand of friendship; laws would then have been framed far superior to those with which most of the States have struggled along, and by which the pharmacists failed to obtain the respect and acknowledgment of the public and medical profession. Looking back to those days, we now know that the physicians succeeded, for instance, in presenting their claims to the authorities of the army and navy, and that the highest physician in the army has the rank of General. If Pharmacy had joined Medicine in those days, we might to day have a chief pharmacist with the rank of a Captain or Colonel. But the opportunity was lost, for the importance of the subject was not recognized and in place of presenting a working model law, resolutions of the following type were adopted:

*"Resolved, That the Association, in constructing a form of a law proper to be endorsed and recommended by the Association for general application in all states, are such that we must be satisfied with constructing the broad principles which in our judgment should direct all legislation upon this important subject."*

*"Resolved, That we are well informed and regrettable a rapid increase in the number of accidents which our fellow citizens are now so prone to in dispensing medicinal substances, and that we earnestly desire to see this condition checked and controlled."*

A compromise law was also adopted and it was resolved to send a copy of same to the governors of the different States of the Union.

The second great subject that came up at the meeting in 1869 was the proposition to expel Mr. Frederick Stearns, an ex-President of the Association, an active member at all the meetings and a man of the highest standing among pharmacists and the citizens of his home. Mr. Stearns had brought into the market a medicine for which he had adopted the name of "Sweet Quinine." The medicine, however, did not contain quinine, but cinchonine. The label did not state that it contained quinine, nor was the claim made, anywhere in the circulars, that the medicine contained quinine, the word "cinchonine" with an addition of being a good substitute of quinine was always used. In his explanation Mr. Stearns stated that he had adopted the word "Sweet Quinine" after long and careful consideration. That the medicine contained an alkaloid of the same tree, that the public did not know anything about cinchona, but knew what quinine was and that therefore it was no offense against ethics to use this word, particularly if all the circulars stated what the medicine contained.

The leading men of the Association, however, construed this offence as a direct violation of the code of ethics and claimed that he willfully practiced sophistication and fraud. It will be seen that the question simply turned on the value that is attached to the trade-mark as such. It is well known that in those days, and even afterwards, tradesmen of all kinds hunted for proper and catching names for their products, and it was not generally supposed to be necessary that the name of a trade-mark should be that of its contents. The debate which took place when the proposition to expel Mr. Stearns was brought forth, is one of the most interesting and touching readings of the proceedings of the Association. Everywhere the great service that Mr. Stearns had rendered the Association, his high virtues as a man, his amiability and faithfulness as a friend were extolled,—but he had not been ethical. The address that Mr. Colcord, this old veteran and stern representative of high professional ethics, made at this occasion is apt to bring tears to the eyes of even those that knew nothing of the intimate and true friendship, that up to that time, had existed between the two men. It reminds us of the deep patriotism and stern determination of Brutus when he plunged his dagger into the heart of his foster father; "Not that I love my friend less, but that I love Pharmacy more."

Mr. Stearns could have cleared himself easily if he had made the promise to discontinue the sale of the medicine; but he declined to make any promises. He too, was a man of high honesty and stubborn convictions. He said: "Judge me by what I have done, not by what I promise," and so he was expelled. The Association lost one of its most faithful and active members. During the fifteen years of his membership Mr. Stearns had, at every meeting, helped to uplift Pharmacy, to advocate what was good or right; he was no idealist or enthusiast like Colcord or Parrish; he went about the elevation of Pharmacy with a practical mind and his services were recognized by the Association by electing him to the highest honor of President. That we think more mildly of these things to-day is shown by the fact that he was elected a member some years later and it also shows how deep-rooted his admiration and love for the American Pharmaceutical Association were, when a year or two before

his death, as a successful and wealthy business man he again asked to become a member.

The charge has been made that the foundation of this action lay in commercial competition and envy, and that Mr. Stearns's success prompted a leading man from New York to present these resolutions. But how carefully the reader may look for any proof of this charge, it cannot be shown nor supported by records as they appear in the proceedings.

The question has often been asked why the Association was so severe with one of their best members, and many reasons more or less unsatisfactory have been assigned to this action. The real cause for this severity, however, lies in the peculiar psychological forces that sometimes move the human mind. Every leading man at that meeting felt that the action with reference to the pharmacy law, was unworthy of the lofty standing of the Association. There was that unconscious feeling that a mistake had been made, and that they had failed in the high vocation of the Association. Now, they wanted to assuage this feeling of dissatisfaction by being the severer in the following action. This swinging over, from leniency to severity, and the impression that an error committed in one direction, might be pardoned by extreme methods in the other direction is a human experience, not to say frailty. It shows itself daily in the individual, it appears in societies, in nations.

The history of the great men of the ancient Grecian republics is full of such sudden changes from admiration to contempt, from exalting to condemning. We, too, have had many instances of it in our own history. The treatment of the hero of Manila in the last Spanish war furnishes a good example. If the proposition made and earnestly urged by some members to censure Mr. Stearns and lay the matter over for a year had prevailed, Mr. Stearns would not have been expelled. The psychological excitement would have worn off and a cooler and quieter judgment been passed. But no matter in what light the individual may consider this action of the Association, it established one great fact, the importance of which overshadows everything else, and it is for this reason that your historian has given this subject so much time and investigation. The expulsion of Frederick Stearns impressed a character on the American Pharmaceutical Association that has not been effaced 'til to-day and never will be effaced. It declared to its members, to the pharmaceutical profession, to the whole world, that strict adherence to pure ethical honesty was its leading and most important feature; that neither long and faithful service, nor success in business, nor personal friendship could interfere with this principle, and that no sacrifice was too great to uphold it. The Association was here put to the most crucial test in its history, the temporary disagreement nearly disrupted it, but it came out of the severe trial victorious, purer and stronger. That the expulsion cast a gloom over the meeting, can easily be understood, and the next day, without further business of any importance, the members adjourned to meet again in Baltimore in 1870.

It must be considered a fortunate incident for the Association that the following meeting in 1870, the eighteenth, became more than anything else a business-meeting, under the influence of the excellent address of the President Ezekiel H. Sargent. He reviewed the affairs of the Association, not only the financial ones,

from the standpoint of a cool, sober, business man, eliminating from his address everything that might look like visionary ideals or enthusiasm. This was fortunate in more than one way; for it turned, for once, the minds of the members from the pursuit of scientific matters and a conception of their high vocation, back to solid facts and put before them the affairs of their work, their efforts and their hopes in sober and concise, even if dry, language.

Through the President's influence, the Association escaped the fate of so many noble and great enterprises, that they lose touch with reality, and, in the pursuits of high and lofty aims, forget the demands and cold facts of common life. President Sargent made a great many recommendations, the majority of which were accepted in the course of the meeting. For instance to supply money for the Committee of Progress of Pharmacy to purchase necessary journals; to create a new committee on adulteration and sophistication, consisting of such rising and enthusiastic men as Joseph P. Remington, Albert E. Ebert and William T. Wenzell; to have a general index of the proceedings of the last decade compiled; to direct the President to appoint authorized agents in the different States for the propagation of the Association; to appoint a Committee to take into consideration the invitation of the International Congress of Pharmacy to meet in the United States in 1876; and to create a committee of five on legislative action in pharmacy and the drug trade in general.

But the most important action of this meeting was the thorough revision of the Constitution and the providing of funds to put the Association on a firm financial basis. This new revision of the Constitution differed from the old one in many points.

It is this revision of the Constitution which, in essentials prevails to-day. Many changes became necessary through the growth of the Association and the establishment of different sections. An exchange of greetings with the Pharmaceutical Conference in England, that met at the same time in Liverpool, took place and an address was also sent to the North German Apothecaries' Association that met in the same year in the City of Dresden.

In the nomination and election of President, for the first time a break was made in the accustomed habit of selecting a new president from the place of meeting. Mr. R. Stabler of Alexandria, Virginia, was nominated and elected for the nineteenth meeting which was to assemble in St. Louis in 1871.

The committee on unofficial formulas was continued and Professor J. Faris Moore appointed president.

Among the many new members who joined at this meeting we notice the name of Charles Rice of New York, who afterwards became such a shining light of the Association.

The report of the committee of Progress of Pharmacy by Dr. Frederick Mahla, was as usual about one-third of the proceedings, and was a worthy continuation of the preceding ones. The committee on legislation in pharmacy in the different States, which had been continued from the previous meetings, reported the enactment of laws in the States of Rhode Island, Maryland and Pennsylvania and while these laws must be hailed as a decided progress in the development of pharmacy, they yet fell short of what they might have been, for reasons stated before.

Although this meeting was principally devoted to practical purposes, there were a long series of excellent papers by some of the leading men of those days. Mr. Joseph P. Remington read a very interesting paper on "Glycerin;" Mr. Squibb again reviewed the process of making fluid extracts and also continued his investigation on Rhubarb. His remarks on the manufacture of "Chloral" were highly interesting and received with great favor. Mr. Diehl pointed out that the indigenous drugs collected in the various parts of the Union were all shipped to New York; that it was sometimes impossible to find goods in Louisville that had been collected in its immediate surroundings and that much difficulty and delay was caused by this. Another paper devoted to "Medicinal Plants of Canada" was that of William Saunders. William Procter, Jr., read a very interesting treatise on "Morphimetric Process for the Pharmacopœia." He reviews the different methods proposed by different investigators and while his investigations lack that perfection which this work has attained at the present time, it yet showed a remarkable progress since 1862, when the committee reported that it was nearly impossible to make such investigations.

It had been customary since 1863 to add to the proceedings a short report on the social features of the Association, a custom that is continued to the present day. Another report that was handed in every year in those days, was a report on exhibits and specimens. It is to be regretted that the interest in this part of the annual meeting has disappeared, and that for many years such exhibitions have not taken place. The reason for it, if the historian is correct, is that these exhibitions took the feature of strictly commercial enterprises, while, in the beginning, specimens of all kinds of indigenous and foreign drugs, samples of rare plants, chemicals of special appearance or combinations, in fact, articles that tended to instruct and educate, were the main features of these exhibitions. The efforts to display living plants collected in the vicinity of the place of meeting that have lately been made, are good substitutes for these old exhibits and it is to be hoped that through their influence, the exhibits of educational subjects will gradually be revived. It was customary in those days for the Association to adjourn at a certain time that was fixed beforehand, for the purpose of visiting the exhibits.

With this meeting the second part of the history of the American Pharmaceutical Association may justly be closed. There is a remarkable difference between the first and the second decade. In the first part the minds of the members soared on high. The meetings were conducted by their founders and the lofty ideals which had prompted these noble men to found the Association, were the leading inspirations of the meeting. The great political upheaval in the beginning of the "60s" naturally checked this ideal tendency in many respects and plain business considerations and sober thought took their places. This condition of affairs far from having injured the Association, was of enormous benefit and gave it strength and firmness. It was now not only well known and established in the United States but it had created attention and congratulations in other countries and it had boldly reached out for the International Congress of Pharmacy to be held on this hemisphere.

Another good feature in the development of the Association must be noticed

The old members who founded the Association were not jealous of the younger; with pride they saw the young men come in, they welcomed them cheerfully, they willingly gave them an opportunity to show their mettle and take active part in the workings of the Association. We have, therefore, in this decade, the first papers, the first words of mental individuality and scientific thought of so many new men, and it is a pleasure to notice how their sometimes impetuous and radical desires, were wisely checked and guided by the older men without any desire or effort to suppress their individuality.

Thus the Association was ready to reach out further and do greater and nobler work.

---

JOHN B. BOND, M. D.

Doctor Bond, the Chairman of the State Board of Pharmacy of Arkansas and a member of the American Pharmaceutical Association since 1883 attained the ripe age of seventy-eight years in November. He was born at Gettysburg, Pa. in 1836, but made an "early escape,"—as he gleefully terms it,—to Missouri where he was educated and grew to manhood. His early life was spent upon his father's farm, after which he "tried his luck" in California for three years. He then returned to Missouri and joined the Confederate Army being attached to the Medical Corps of the Division of General Sterling Price, his qualifications for that position being that he had studied medicine in the St. Louis Medical College, now known as Washington University. He attained the rank of Chief Surgeon of Little's Division, Price's Corps, then serving in Mississippi, and while acting as such officer, he saw General Little receive his death-wound at the battle of Iuka. Soon after this lamentable episode, Dr. Bond was made Medical Purveyor on the staff of General Holmes, and was assigned to duty in Arkansas. Here he met "his fate" in the "Belle of Little Rock," whom he espoused, and thereupon transferred his citizenship from Missouri to the "Bear State."

At the close of the Civil War he practiced medicine until 1872 when he embarked in the drug business, being the senior member of Bond's Pharmacy Co. of Little Rock.

He occupied the Chair of Chemistry of the Medical Department of the University of Arkansas for three years.

He was one of the organizers of the Arkansas Association of Pharmacists and was prominent in the enactment of the Arkansas Pharmacy Law, which is considered a most equitable and satisfactory law for a frontier state requiring but some additions concerning the enforcement of the law to make it a model one. For twenty years Dr. Bond has been the President of the Arkansas State Board of Pharmacy.

## Section on Education and Legislation

Papers Presented at the Sixty-Second Annual Convention

### MINUTES OF THE SESSIONS OF THE SECTION ON EDUCATION AND LEGISLATION.

#### FIRST SESSION.

The first session was called to order by Chairman Craig at the Hotel Pontchartrain on Wednesday morning, August 26th, at 9:30 a. m.

The first business being the reading of the Chairman's Address, Mr. Marshall was requested to take the Chair during its reading. [Chairman's Address printed in this issue.]

On motion of Prof. Sayre, seconded by Mr. Richardson, the address was referred to a committee of three to report thereon at this meeting; said committee to consist of Prof. Day, and Doctors Ruddiman and Wilbert.

Chairman Craig resumed the Chair and called for the Secretary's Report. Secretary Freericks read his annual report. [Printed in this issue.]

On motion of Mr. Mayo, seconded by Dr. Wilbert, the report was referred for publication, and the thanks of the Section were extended to the Secretary for his able and comprehensive report.

The Report of the Special Committee on Postal Regulations for the Mailing of Poisons was presented by the Chairman of that Committee, Mr. Mayo, and on motion of Prof. Day, seconded by Mr. Weinstein, the report was accepted and referred for publication, and the committee was discharged from further consideration of the subject.

Papers were read by Mr. Frank R. Eldred and Dr. Wilbert upon the proper enforcement of Drug Laws, both of which papers were referred for publication. [Papers printed in this issue.]

Mr. Mayo presented a resolution opposing the taxing of proprietary medicines. The motion was seconded by Mr. Wallace, and was adopted and referred to the Council.

Chairman Craig read a paper by Dr. Jacob Diner, on Pharmaceutical Education, and on motion of Mr. Mayo, seconded by Mr. Bodemann, it was referred for publication.

The report of the Syllabus Committee was read and on motion of Mr. Weinstein, seconded by Dr. Stanislaus, the report was received and approved and the recommendations therein made referred to the Council for action.

On motion of Mr. Richardson the Section adjourned.

#### SECOND SESSION.

The meeting was called to order on Thursday morning, at 9:30 a. m., by Chairman Craig. The reading of the minutes of the previous meeting was dispensed

with. Nominations for Officers of the Section were made as follows:— For President, Matthias Noll of Kansas, and Frank H. Freericks of Ohio; for Vice-Chairmen, Prof. Zada M. Cooper, and Messrs. W. S. Richardson and George B. Topping; for Secretary, Prof. R. A. Kuever of Iowa.

The Committee on National Legislation made its report through its Chairman, Mr. John C. Wallace. On motion of Prof. Sayre, seconded by Dr. Rusby, the report was accepted and referred for publication.

Prof. Army moved that the recommendation to approve the principle of Price Standardization be referred to the House of Delegates. Mr. Freericks moved to amend by adding the words, “be referred with the approval of this Section.” The motion as amended was adopted.

The report of the Delegates to the Drug Trade Conference was presented by Chairman Wallace. [Printed in September, 1914, issue.] On motion of Dr. Anderson, seconded by Prof. Army, the report was accepted and adopted and the recommendation that the Association continue its membership in the Drug Trade Conference was approved.

An open discussion was then held upon the question submitted by Chairman Craig:— “The necessity of getting representation of the various interests embraced in the Association, in the consideration of Legislative Matters.” This discussion was opened by Secretary Freericks, and participated in by Messrs. Sayre, Woodruff, Wallace, Anderson, Weinholt, Abbott, Army, Mason, Rusby and Jordan. On motion of Prof. Jordan, seconded by Mr. Weinholt, the entire discussion was placed upon the table, and a motion to have a part of the discussion printed was declared out of order.

Prof. Sayre presented the report of the Committee on Drug Reform, and on motion of Dr. Rusby, seconded by Dr. Anderson, the report was accepted and referred for publication.

Dr. Stewart presented the report of the Committee on Patents and Trade-marks. On motion of Mr. Bodemann, seconded by Mr. Richardson, the first part of the report was referred to the Committee on Proprietary Medicines, and the resolutions contained in the report approved. [Printed in November issue.]

Associate Chairman Marshall then assumed the Chair and the report of the Committee on President’s Address was read. [Printed with Chairman’s Address.]

Dr. Anderson moved the adoption of the Report. Motion seconded by Mr. Richardson, and adopted.

The following officers were elected for the ensuing year:—

Chairman, Frank H. Freericks; Vice-Chairmen, W. S. Richardson, Zada M. Cooper and George B. Topping; Secretary, R. A. Kuever.

The Section then adjourned.

#### THIRD SESSION.

Section called to order by Chairman Craig. In the absence of the Secretary, Mr. W. S. Richardson acted in that capacity.

Papers were read as follows:—

On Pharmaceutical Education, by Frank R. Eldred.

Comparison of Lectures and Laboratory Practice, by W. B. Day. [Printed in this issue.]

A Plea for a Higher Standard for Entrance to Pharmacy, by C. B. Jordan. [Printed in this issue.]

Comparative Advantages of Practical Experience and General Education as a Prerequisite for Instruction in Schools of Pharmacy, by Dr. Rusby. [Printed in this issue.]

Dr. Anderson offered a resolution in approval of the Harrison Bill, which was adopted by the Section.

Adjourned.

---

### ADDRESS OF THE CHAIRMAN.

---

If one but glance over Article I of the Constitution of this Association, he will conclude that the founders of the organization builded not for a clearing house of pharmacal thought, but for a militant organization resistant to the evils that then threatened, and now more direfully threaten, the calling, and active to overcome the lethargy in regard to educational, ethical, and professional standards, that hampers pharmacal progress. They hoped for a protagonistic organization, not an association of mere proclaimers. Quite well, along many lines, have their ideas been advanced, but the progress has not been what an active membership would have made it. Discussion there has been in plenty and some action too. That there has not been more action is no fault of the organization; there has been lacking among the individual members, that spirit, the lack of which differentiates the American from the citizen of other countries, that spirit of seeing to it that law-makers and law-officers take care of the law, of seeing to it that this board, or that body, performs its duties as they should be performed.

Have you, or have I, pointed out the short-comings of boards of pharmacy as servants of the law? Have we endeavored to rid pharmacy of the man who we knew full well was a detriment to the entire calling? Have you, or have I raised any objection to the fraud perpetrated by the so-called "school of pharmacy" that graduates with a mark of 98 *per cent*, a young man who cannot write the full Latin name for epsom salt, or calculate the amount of a one-in-forty dilution of atropine sulphate required to make ten one-two-hundredth-grain dosages, or roll the corners off a pill? Have we not known the so-called "pharmacist" who would refill a prescription container from another pharmacy after smelling the receptacle and reading the label? Have we complained to the proper authorities concerning him? Have we exposed the druggist whom we knew was immorally, and perhaps illegally, selling narcotics? No; we have minded our own business—and let that business suffer from what really was neglect.

Along which of the two lines embraced within the purview of this section, education and legislation, we could achieve most for pharmacal advancement depends upon our bent and upon our environment. Legislation, to me, appears to be an over-exploited remedy for pharmacal ills. Education for pharmacists and for the public is of course a slower method of achievement and a method that requires constant attention; for public opinion, and pharmacal opinion as well

is evanescent—but education is a surer method; for, without education, legislation fails utterly.

There are so many problems in present-day pharmacy, that are being studied for solution along legislative lines, that they can merely be mentioned in an address that must necessarily be brief—a chairman, as I see it, should formulate and direct the program for his section, rather than occupy the greater portion of it. Others who will come before you will tell of the past year's endeavors to standardize all sorts of things from the shape of tablets of mercuric chloride to the graduations of nursing bottles. They will tell you how accroached rights and public welfare have clashed in the struggle against the drug evil; how the medicine pedler has practiced pharmacy, and the dispensing doctor has been above the law, a law apparently enacted for the protection of the public, but more evidently for the restriction of the pharmacist. When they have told you these things, do you, I pray, read the first article in your constitution and enlist in the endeavors that it purposes?

Let me call your attention to some educational needs of pharmacy; there are but two important among these. One important need is education; the other is educators. The need for education is two-fold. The pharmacist should be an educated man and the man in pharmacy should be an educated pharmacist. Slowly but surely there is dawning in general educational circles the light whose rays were first focalized by Froebel, the light that shows that to do is to know; and sense-training is fast taking the place of memory-cramming in educational methods. Glad will be the day when this light illumines pharmacal education when the pharmacy student's thoughts are directed toward the real purpose of instruction, the imparting of that knowledge that constitutes education, and away from the examination at the end of the semester or the tests by the board of pharmacy; when he comes to look upon instruction as a means toward an end and not as an end in itself.

The preliminary education that the pharmacy student should have, has been standardized to a certain extent, but apparently it has been standardized for the sake of standardization rather than for the purpose of getting an educated pharmacist. Mathematics, physical science, introductory chemistry, logic—these are necessary in the foundation of any professional education. They are usually conspicuously absent from among the counts upon which the pharmacy student certificate is granted. None can be of service to pharmacy who is but crammed with learning and has not the initiative that is the first characteristic of education. Look over a lot of theses prepared by candidates for a degree in pharmacy, even for the doctorate: What initiative, what originality, do they indicate? The fault is not all in the teaching of pharmacy; much of it lies farther back in the educational life of the student; and pharmacal instruction has a difficult task in building a trained professional man upon no other foundation than a crammed memory.

That there is a lack of efficient pharmacal educators is evident to any one who has any knowledge of educational methods and educational results. It is not enough that a man be an authority in his subject, to make him an efficient instructor of others. If he has not a thorough knowledge of human nature and at least a fair grasp of the psychology of imparting and receiving instruction, he

cannot instruct. The real teacher can tell through observation of the faces before him—he needs not wait for the examination to determine it—which, among his students, are memorizers, which miss the point of the instruction entirely, and which catch and fix the idea independent of the words in which it is expressed. There is a need for trained educators in pharmacy and this Association should endeavor to remedy it.

Few of us have not heard criticism of the apparent divergence of the lines along which schools of pharmacy and boards of pharmacy, determine the fitness of practitioners of pharmacy. That there is a divergence is evidenced by some statistics collected by my associate, Mr. R. A. Kuever, which show that of 1,497 graduates of pharmacy schools, examined recently by seventeen boards of pharmacy, only 65.06 *per cent.* were passed. Can we say, therefore, that the schools of pharmacy are not doing their duty? Is it, on the other hand, that the boards of pharmacy are poor judges of pharmaceutical fitness? This is a question that this Association might well take under consideration. Some other figures collected by Mr. Kuever are interesting in this connection. He found that thirty boards of pharmacy examined five thousand three hundred and ninety-three applicants for registration in a given period and passed 54.55 *per cent.* Twelve of these boards had examined graduates, so-called, of short-course, or cramming, schools, to the number of three hundred and ninety-one. Of these 49.36 *per cent.* were passed. Evidently the regular school of pharmacy is a little better judge of pharmaceutical fitness (on a board standard) than is the cramming school. As far as Mr. Kuever was able to ascertain, there are twelve of these cramming schools that are well known; this number does not include the correspondence-course institutions. These cramming schools are without standards; but they get half their students past the board,—and to pass the board is the chief desire of by far the greater number of pharmacy students.

There are many legislative problems upon which the chairman might base recommendations to this section, but I prefer to leave these to the several committees and delegations that have to do with legislative matters. Let me, however, suggest that you take an active part in the attempts to restrict the traffic in narcotics to moral lines, paying particular attention to the necessity for the restriction of physicians and especially veterinarians who are not amenable to very stringent laws of any sort; that you do not overlook the present-day opportunity to achieve a much-desired reform in our patent laws relative to medicinal products; that you leave not to the civic organizations the survey and regulation of the practice of pharmacy; that you cooperate in the conservation of real pharmacy; that you, in short, become protagonists for the purposes set forth in Article I of the Constitution of the American Pharmaceutical Association.

In the educational field, I would recommend: (1) That this Association create a committee to survey pharmaceutical educational methods.

(2) That this Association take steps toward the supplying of efficient pharmaceutical educators trained along pedagogic, as well as pharmaceutical, lines.

(3) That this Association interest itself in the modern movement toward the concrete and practical in general educational practices.

(4) That this Association concern itself with the coordination of the methods

of schools of pharmacy and boards of pharmacy, particularly that practical pharmacy may be conserved.

(5) That this Association take steps toward securing the better enforcement of the statutory provisions that safe-guard the practice of pharmacy.

As a topic for discussion at the meetings of state pharmacal organizations next year, I suggest this:— "Should the Ownership of a Pharmacy be Restricted to a Registered Pharmacist?"

Respectfully submitted,

HUGH CRAIG,

Chairman.

---

REPORT OF COMMITTEE ON CHAIRMAN'S ADDRESS.

Your committee, to whom was referred the address of Chairman Craig, takes this opportunity to express its appreciation of the excellence of the address, its admiration of the sentiments therein contained and its concurrence with the suggestion offered for the improvement of pharmaceutical education and legislation.

We endorse the recommendation that the Association use its best efforts to secure such restrictions of the traffic in narcotics that shall include all who are responsible for the abuses in the dispensing or sale of narcotics.

We endorse also the recommendation relative to the reform of our patent laws concerning medicinal products; likewise, the suggestion that pharmacists themselves should undertake the survey and secure the regulation of pharmacal practice, and not leave these vital matters to organizations which are non-pharmacal in character.

We believe that the survey of educational methods mentioned by our chairman should be carefully considered by this section, and, that a committee should be appointed to report a plan of classifying all the various institutions now engaged in giving instruction in pharmacy in this country.

We advise that the recommendation of our chairman concerning the co-ordination of the methods of schools and boards of pharmacy be made a subject for discussion and action at the joint session of schools and boards with this section and to the same joint session we would refer the recommendation that steps be taken to secure the enforcement of the statutory provisions that regulate the practice of pharmacy.

We approve of the chairman's suggestion of submitting a topic for discussion at the meetings of state pharmaceutical associations next year, and, we recommend that the secretary of this section communicate this suggestion to the secretaries of the various state pharmaceutical associations.

W. B. DAY,

M. I. WILBERT,

E. A. RUDDIMAN.

REPORT OF THE SECRETARY.

---

This report of your Secretary, in keeping with custom, will be largely devoted to legislative changes which have taken place during the year and to rulings and court decisions of importance. An effort has been made to compile some matter of possible historical and statistical interest pertaining to institutions of pharmaceutical learning, but owing to lack of response in some instances, this work as originally planned has not been fully completed, but it is nevertheless made a part of this report, so that if deemed of sufficient interest, it may be completed by some subsequent Secretary.

## LEGISLATIVE ACTIVITY.

During the year, apart from the United States Congress, there have been legislative sessions in Alaska, Georgia, Kentucky, Louisiana, Maryland, Massachusetts, Mississippi, New Jersey, Rhode Island, South Carolina, Vermont and Virginia. In nearly all of these legislative bodies, bills were submitted which in one manner or another were of interest to pharmacy. Aside from the United States Congress laws pertaining to pharmacy were enacted only in Massachusetts, New York and Rhode Island. Since the scope of intended legislative activity was of a nature to cover a very broad field, it seems best that only actual enactments or such measures as are yet likely to be enacted, find consideration.

*Massachusetts:*—In Massachusetts a law was enacted to further regulate the sale of the important narcotics other than cocaine, the sale and disposition of which was covered by an enactment of the previous year. A complete copy of this new Massachusetts law, is made a part of this report, because of its special interest.\* An analysis of the new law brings out the following special features, which are not generally found in such legislation as proposed at this time. Preparations sold in good faith for diarrhea, cholera, neuralgia, may contain six grains of opium or three-fourths of a grain of morphin to the fluid or avoirdupois ounce. Dover's Powder and veterinary preparations containing not over ten grains of opium, or one and one-fourth grain of morphin, to the ounce, and compound medicinal tablets, pills and powders, containing not more than one-twentieth of a grain of morphin, or one quarter of a grain of codein to each pill, powder or tablet, are also specifically exempted, when distributed in good faith. Veterinarians are specifically prohibited from prescribing the drugs for human-beings, and Physicians and dentists are prohibited from prescribing the drugs for persons known by them to be habitual users. This last named provision is immediately qualified by another provision, which sets out that nothing in the Act shall prevent practitioners of medicine, dentistry or veterinarians, from prescribing or using the drugs whenever indicated for any patient, so long as it is not done to evade the provisions of the Act. Physicians, dentists and veterinarians are required to keep a record of the names and addresses of all patients to whom they dispense the narcotics. Persons who falsely represent themselves as physicians, pharmacists, or others legally authorized to secure the drugs are made violators of the Act. It will be noted that much was sought to be accomplished by this new law, but its spirit appears to extend far beyond its actual letter. The requirement upon physicians, etc., to keep a record of the names and addresses of patients to whom they dispense the narcotics seems of little value, because they are not required to state the quantity dispensed and the day of dispensing. The law seems to properly distinguish between dispensing and administration, for it is evidently not required that a record be kept of the drugs which are administered.

*New York:* During the year New York has enacted three laws which are of special interest. One of these, known as the Boylan Law, like the Massachusetts Act already referred

---

\* See appendix.

to, provides regulations for the distribution of narcotic drugs other than cocaine, which is governed by an act of the previous year. Another, known as the Walters Law, governing hours of employment, and finally a new Trade Mark Law. The Walters Law provides separate regulation to govern work hours and employment in pharmacies and drug stores, as differing from work hours for employment generally, and seems to limit authority for the enforcement of laws governing employment in drug stores with the general authorities having in charge the enforcement of Pharmacy Laws.

The New Trade Mark Law makes the following a misdemeanor under heavy penalty.

"A person who shall knowingly sell, offer or expose for sale any article of merchandise, and shall orally or by representation, name or mark written or printed thereon, or attached thereto, or used in connection therewith, or by advertisement, or otherwise, in any manner whatsoever, make any false representation as to the person by whom such article of merchandise or the material thereof was made, or was in whole or in part produced, manufactured, finished, processed, treated, marketed, packed, bottled, or boxed, or falsely represents that such article of merchandise or the material or any part thereof has or may properly have any trade-mark attached to it or used in connection with it, or is or may properly be indicated or identified by any trade-mark, is guilty of a misdemeanor."

The law seems principally to be aimed at substitution, and within its provisions would undoubtedly be included the sale in bulk of articles which are sold from original containers and regarding which the practice of substitution may have been more or less prevalent.

The Boylan Law is intended to govern the sale of chloral, and of opium and its alkaloids, salts and derivatives. Because of its many important and new features, it is made a part of this report in its entirety. [The bill was printed in full in the Journal of June, 1914, P. 902. Ed.] The following provisions are deserving of special attention. Sales may be only on physician's prescription other than for preparations containing minimum quantities, and the prescription must contain the name of the physician, etc., his office address, office hours, telephone number, name, age and address of person to whom and date on which it was issued. Physicians may not issue a prescription to any person unless they first have made a physical examination of such person and then find the drugs to be indicated. Prescriptions containing more than four grains of morphin, thirty grains of opium, two grains heroin, six grains of codein, or four drams of chloral, must first be verified by communicating with the prescriber. Prescriptions may not be filled later than ten days after they have been issued. Persons filling a prescription must either issue a certificate or show on the label, the name and address of the persons selling, the name and address of the physician, etc., date of sale, and name of person to whom such sale is made. Possession of the named drugs by any person other than those legally authorized to handle them, is a misdemeanor, unless such possession is authorized by the certificate or label in question. Purchases and sales in the trade must be made on official order blanks furnished by the local Health Board, and such blanks can be had only by persons legally authorized to handle the drugs. Physicians, druggists, pharmacists, veterinarians and dentists must keep on record the name and address of each person to whom they administer or dispose of the drugs, together with the quantity so disposed of or administered. Hypodermic syringes may be sold only on the written order of a physician or veterinarian, and a record of such sale must be kept. Provision is made for the commitment of habitual-users to hospitals or institutions which are licensed under the State Lunacy Commission. Provision is made for the revocation of licenses issued to physicians, dentists, veterinarians, pharmacists or nurses upon proof that the licensee is addicted to the use of habit-forming drugs.

It is not the purpose of this report to discuss to any extent the provisions of this new New York Law, but attention is called to the fact, that the requirement for a certificate to the purchaser or alternatively to show the same matter on the label would include the need for setting out the contents of the drugs named. The advisability of making this requirement may be doubted. The purpose of course is, to enable the possessor of such drugs to prove lawful possession, but, in actual practice, the purchaser for legitimate use is not apt to have preserved such certificate in case he should be called upon. To require physicians to keep a record of the drugs which they themselves may administer seems an unnecessary burden, while the requirement for them, as well as druggists, pharmacists, etc., to keep a record of name,

address and quantity dispensed or disposed of, places New York in the foremost rank of those states properly seeking to control the narcotic evil, that is, of course, if the law is to be extended in this respect to cover all narcotics.

*Rhode Island:*—In Rhode Island an amendment to the narcotic laws of that state was enacted, looking toward the better enforcement of said law. The amendment provides, as of special interest, that no person, other than a manufacturer or jobber of drugs, wholesale druggists, registered pharmacists or assistants, registered physicians, dentists, or veterinarians or others who under the law are entitled thereto, may possess the drugs, unless possession can be shown to be under a physician's prescription.

#### FEDERAL LEGISLATION.

During the last and present session of Congress an enormous number of bills have been introduced which are of interest to pharmacists. At this writing none of them have been enacted into law, but it is likely that, at least, some will become laws before Congress adjourns. Among the numerous bills introduced and pending may be mentioned those which would regulate the sale of bichloride of mercury; to provide price maintenance; to prevent unfair competition; the Hinebaugh Bill to tax mail order houses; in general, either amendatory or supplementary to the Sherman Anti-Trust Act; to amend the Food and Drug Act; the Hughes-Bacon Bill to improve the condition of pharmacists in the Army; to prevent fraudulent advertising; to regulate the use of trading stamps and coupons; to amend the present patent laws; the Harrison Anti-Narcotic Bill, and many other legislative proposals touching upon almost every activity in which the pharmacist is interested. It is to be regretted that no progress has yet been made in securing a law to improve the status of pharmacists in the Army.

Of the many national legislative proposals, it will be impossible to discuss other than a few of the more important ones, and among these must, of course, be considered, as of prime importance, the Harrison Anti-Narcotic Bill, the Price Maintenance Bills and the Trade Commission Bill, which includes a provision with reference to unfair competition. Aside from the Harrison Bill, it is impossible even at this time to discuss the various other specially important legislative propositions, because they are being changed almost daily in some form or another, so that it is quite impossible to know from day to day in what form they may be.

The various Price Maintenance Bills now pending in Congress are typified largely by the so-called Stevens Bill, known as H. R. 13305. During the past year most wonderful progress has been made in popularizing the idea of price maintenance and standardization, and the support which has been given to such measures from many different sources, gives ground to hope that the cut-rate evil, which has so sorely afflicted the retail drug trade of the country, will within a reasonable time be largely checked, if not entirely overcome. The Stevens Bill, which is the most popular along this line, would legalize contracts affecting Interstate Commerce, whereunder the original producer or manufacturer will have the right to prescribe the price at which his trade-marked or specially-branded articles shall be re-sold. It is rather noteworthy that this bill does not aim to include patent or copy-righted articles, unless it was thought that their inclusion might lessen the chances for successful enactment. With reference to trade-marked and specially-branded goods, the bill, and others of the same type, are undoubtedly designed to overcome the decision of the Supreme Court in various cases

which held such contract-control to be unlawful. Whether due regard has been given to Constitutional limitation may be a question for more thorough consideration. The intended legislation is framed under the Interstate Commerce authority of the Federal Government, and not under any special authority which the Federal Government has, with reference to trade-marked or specially-branded articles. The question, therefore, may arise as to whether Congress has the legal authority under the Interstate Commerce clause to make special provisions regarding the price of certain articles which enter Interstate Commerce to the exclusion of other articles or property which are also in Interstate Commerce. Whatever the requirement may be ultimately found to be with reference to this matter, there is but little doubt that in some form a measure can be properly framed. For the present, legitimate dealers throughout the country, which include the large number of retail druggists, can be congratulated on the enormous strides which have been made towards legalizing maintenance and standardization of prices. The outlook has never before been so hopeful.

The Trade Commission Bill, which is now pending in the Senate, known as the Newlands Bill, includes, as already stated, a provision against unfair competition, which has found expression in numerous other bills, all having the same purpose. It would seem that much good is looked for by many, to come from this proposed legislation, with particular reference to unfair competition. It is likely, however, that such possible good has been largely over-estimated. Unfair competition is an extremely broad term. It would be found, or not found, according to the state of mind of the person with whom the decision rests. When left for decision to a Commission, such Commission would be bound by the present status of the general law as defined in court decisions. In late years, court decisions, either directly or indirectly, have held certain practices, which the retail trade particularly claim to be unfair competition, as not being unfair. It would seem that any law which would control and restrict unfair competition, as we understand it, should define the practice which must be regarded as unfair; and in the absence of such definition, little, if anything, will be gained.

Harrison Bill:—Faulty features which were recognized by some to be contained in the Harrison Anti-Narcotic Bill have during the year been largely corrected. In the end, absolute necessity for making the record-keeping requirement applicable to physicians, dentists and veterinarians was also more generally recognized, and an amendment proposed which to a large extent will be helpful in correcting the early defect. On the other hand, these needed changes in the bill have served to make plain that the real opposition to effective and sufficient control over the sale and use of narcotics is found with some part of the medical profession and those who are allied with them. This opposition found expression in an amendment as offered by Senator Pomerene, which is intended to exempt the physician and others altogether from the operation of the proposed law. In just what form the Harrison Bill will now be enacted, it is not possible to say. It may not be enacted at all at this session of Congress, which certainly is to be desired if the law is not to contain a requirement for record-keeping equally applicable to all.

There have been a number of court decisions and department rulings and regulations which are of vital concern. Among them as of greatest importance reference should be made to the following:—

*Itinerant Vendors:*—During the year a decision of the Supreme Court of the United States on the Louisiana Itinerant Vendors Law, has attracted general attention. The decision is of importance. It was rendered in the case of *Baccus vs. the State of Louisiana*. It appears from a statement of facts, that the sale of drugs and medicines in any form by itinerant vendors is prohibited under the Louisiana Law. A number of defenses were set up under which it was claimed, that the act in question was unconstitutional, both under the State and under the Federal Constitution. The finding of the Louisiana Court was against the defense, and a conviction entered, and the case was then carried to the United States Supreme Court. Chief Justice White, rendering the decision for the Supreme Court, in substance merely found that the law was not in conflict with the Federal Constitution. It of course is a recognized fact that the police powers belong exclusively to the several states, and where a measure must be recognized as one exercising the police power, and is not altogether unreasonable, it cannot be declared unconstitutional under the Federal Constitution, after having been held constitutional under the State Constitution. While the opinion of Chief Justice White, contains expressions which would uphold the Louisiana Law, regardless of this limitation, the limitation, nevertheless, must be regarded as controlling. The decision of the United States Supreme Court in this case, really means, that it will not disturb the decision which may have been rendered by the highest court of the several states on a question of this kind. It will be remembered, that the Illinois Court of Appeals, held an Itinerant Vendor's Law of that state to be in conflict with the constitution of the state, and had it been possible to carry that decision to the Supreme Court of the United States, it is altogether likely, that it would also have been affirmed. Therefore, notwithstanding the decision of the Supreme Court of the United States in this case, it is optional with the State Courts of every state other than Louisiana, to reach a decision directly opposite to the one announced by the Louisiana Courts. It is likely, that the courts of most states will continue to hold, that an Itinerant Vendor's Law must be uniform in application, either in that it will apply to itinerant vendors of all kinds in like manner, or that its uniformity will be based on making a distinction between qualified and unqualified vendors, whether they be itinerant or not.

*Saccharin Law:* Legislation and rulings have been quite general to prevent the use of saccharin in food-stuffs and soft-drinks. A law preventing the use of saccharin in soft-drinks was lately held by the Missouri Supreme Court to be discriminatory, and therefore unconstitutional, because it was not made applicable to food-stuffs in general.

*Insecticide Law:* In Ohio an Insecticide Law of such wide scope as to include, practically, every drug which may be used as an insecticide or fungicide, and requiring special license and labeling has been successfully contested in the lower courts. The Ohio Commission, with whom the enforcement of this law rests, have averred that they had no intention to construe it beyond reasonable bounds, but the letter of the law certainly would permit them to do so, and a ruling by the National Insecticide and Fungicide Board of the Department of Agriculture, under the National Insecticide Act, with reference to peroxide of hydrogen, would certainly indicate, that there can be a disposition to extend the widest possible scope to such law.

*Philippine Formula Labeling Law:* A reference to this is possibly not appropriate under decisions and rulings, but it is of such importance as to deserve notice. This new Philippine Law will compel the labeling of all patent and proprietary medicines with their complete formulas. There seem to be some authority with the Department of State to modify legislation in the Philippine Islands, but without such possible modification, the law in question became effective July 1st.

*The New York Health Department:* Some of the late actions of the New York Health Department, would indicate that said department is clothed with unusual powers. The action of this department in this respect, is of special interest, because it has amended the

Sanitary Code by prohibiting entirely the sale of preparations which contain the generally permitted minimum quantity of narcotics, and has also adopted an ordinance which prohibits the use of wood-alcohol in preparations of all kinds intended for internal and external use. One not conversant with the constitutional limitations which govern the New York City Health Department, can hardly understand the wide authority which it would exercise. Evidently, this department is the first one of those which seem to have legislative authority, to go so far as to prohibit the sale of preparations containing a very slight quantity of narcotics, such as paregoric, etc. The action of the Health Department is also remarkable in view of the Boylan Law just enacted in New York State, and wherein at least by indirection, preparations containing minimum quantities are exempted. If there are no constitutional limitations, which would prevent the New York Health Department from enacting such a provision, after the enactment of a general law by the State, then it must be doubtful as to whether there be any constitutional limitations to govern said Body.

*Parcel Post:*—The wide discretion and authority given the Postmaster General with reference to the Parcel Post Law, has already caused the extension of parcel post facilities beyond what Congress was willing to specifically provide. Even greater extensions appear to be contemplated, and the present Postmaster General seems to be willing to go far beyond the limits which would prevail, if Congress had retained to itself the power of extension.

*Postal Laws Governing the Transmission of Poisons:*—With reference to the use of mails for shipping medicinal preparations, postal regulations continue to be in an unsatisfactory state. Changes have been proposed both by the Drug Trade Conference and by the Drug Trade Section of the New York Board of Trade. The greatest difficulty in finding a proper solution for this problem, which has confronted the Postal Authorities, seems to rest in the fact, that a definition for the word "Poison" yet remains to be found.

*Treasury Decision regulating the Importation and Sale of Cocain:*—During the latter part of last year a decision was rendered by the Treasury Department under which it was sought to practically control the distribution of cocain and its derivatives, as well as coca leaves in all channels throughout the country inclusive of importation. Under the decision, every person desiring to secure the articles in question, is required to declare, that they are intended to be used in good faith, and in a manner not dangerous to health. The declaration-requirement appears so broad as to include even such declaration from a person receiving the drugs on prescription. The decision would appear to be an altogether impossible one beyond that part which governs importation. The Bureau of Chemistry, at an early time, announced that it did not find in the decision the wide scope which plainly appears to be therein, and held, that the requirement did not apply to distribution on physicians' prescriptions. While the decision may be enforced, as with reference to importation, it does not appear, generally, to have been extended beyond that point.

*Guaranty under the Food and Drugs Act:*—The three Secretaries having supreme control over the Food and Drugs Act and its enforcement, early in the year, rendered a decision to abolish the guaranty requirement to be shown on packages of food and drugs. This requirement is too well understood to need discussion. The order abolishing the requirement was first to become effective with May 1st, 1915, but a subsequent order was made postponing this to May 1st, 1916, and as to products already packed and labeled prior to that time, to November 1st, 1916. Under the change as proposed, guarantees are to be made on invoices, or in other manner apart from the product. While it may be true that the guaranty legend has been misused in the sense of causing misunderstanding and practical misrepresentation, there is no good reason for going from one extreme to another. To place the retailer in a position where he will be dependent upon his invoices, to prove that the responsibility rests with someone else, seems to be entirely uncalled for. In this connection it is to be noted, that many manufacturers most heartily approve of the new ruling. The thought has been advanced from different sources, that the danger of deception and misunderstanding, might be entirely avoided by abolishing the use of the word "Guaranty", and by making the requirement simply to show serial number under the Food and Drugs Act; requiring such exact wording as under the ruling, would be held equivalent to the Guaranty. Such method certainly appears likely to produce far better and more satisfactory results.

## APPENDIX.

## MASSACHUSETTS NARCOTIC LAW.

An Act to regulate the sale of opium, morphin and other narcotic drugs.

Section 1. On and after the first day of January, nineteen hundred and fifteen, it shall be unlawful for any person, firm or corporation to sell, furnish, give away or deliver any opium, morphin, heroin, codein, cannabis indica, cannabis sativa, or any preparation thereof, or any salt or compound of the said substances, except upon the written prescription or written order of a registered physician, dentist, or veterinary surgeon, bearing the name of the physician, dentist, or veterinary surgeon giving it, which prescription when filled shall show the date of each filling and shall be retained on file by the druggist filling it for a period of at least two years, and it shall not again be filled except upon the order of the prescriber, given in person or in writing. The prescription shall not be copied, except for the purpose of record by the druggist filling the same, and it shall at all times be open to inspection by the officers of the state board of health, the board of registration in pharmacy and its authorized agents, and by the police authorities and police officers of cities and towns. But the provisions of this act shall not apply to prescriptions, nor to the sale, distribution, giving away, or dispensing of preparations and remedies, if such prescriptions, preparations or remedies do not contain more than two grains of opium or more than one quarter of a grain of morphin, or more than one quarter of a grain of heroin, or more than one grain of codein, or more than one-half of a grain of extract of cannabis indica, or more than one-half of a grain of extract of cannabis sativa, or any salt or compound of any of them in one fluid ounce, or, if a solid or semi-solid preparation, to the avoirdupois ounce; nor to liniments, ointments or other preparations which are prepared for external use only; nor to preparations containing any of the said substances which are sold in good faith for diarrhea or cholera or neuralgia, and which do not contain more than six grains of opium or more than three quarters of a grain of morphin to each fluid ounce, or, if a solid or semi-solid preparation, to the avoirdupois ounce; nor to Dover's Powder; nor to veterinary preparations containing not over ten grains of opium or more than one grain and a quarter of morphin to each fluid ounce, or, if a solid or semi-solid preparation, to the avoirdupois ounce; nor to compound medicinal tablets, pills or powders containing not over one twentieth of a grain of morphin or one quarter of a grain of codein or any of their salts, except heroin, to each pill, powder or tablet; provided that such preparations, remedies or prescriptions are sold, distributed, given away or dispensed in good faith as medicines, and not sold for the purpose of evading the provisions of this act.

Section 2. It shall be unlawful for any practitioner of veterinary medicine or surgery to prescribe any of the drugs mentioned in section one of this act for the use of a human being, and it shall be unlawful for any physician or dentist to prescribe, sell, give away or deliver any opium, morphin, heroin, codein, cannabis indica, cannabis sativa, or any preparation thereof, or any salt or compound of said substance to any person known to such physician or dentist to be an habitual user of those drugs.

Section 3. The provisions of this act shall not be construed to prevent any lawfully authorized practitioner of medicine or of veterinary medicine or of dentistry, from prescribing, administering or dispensing any drug that may be indicated for any patient under his care; provided, that such prescribing, administering or dispensing, is not for the purpose of evading the provisions of this act; and provided, further, that every physician, veterinarian and dentist shall keep a record in a suitable book of the names and addresses of all patients to whom he dispenses narcotics.

Section 4. Any manufacturer or jobber and any wholesale druggist and any registered pharmacist, physician, veterinarian or dentist may sell opium, morphin, codein, heroin, cannabis indica, cannabis sativa, or any preparation thereof, or any salt or compound of such substances to any manufacturer, jobber, wholesale druggist, registered pharmacist, physician, veterinarian or dentist, or to any incorporated hospital; but such substances or preparations, except such as are included within the exemptions set forth in section one shall be sold only upon a written order duly signed by such manufacturer, jobber, wholesale druggist, pharmacist, physician, veterinarian, dentist or superintendent of such incorporated hospital, which order shall state the article or articles ordered and the date. The said orders shall be kept on file in the laboratory, warehouse pharmacy or store in which they are filled by the proprietor thereof, or his successors, for a period of not less than two years from the date of delivery, and shall be at all times open to inspection by officers of the state board of health, members of the board of registration in pharmacy, or their authorized agents, and by the police authorities and police officers of cities and towns.

Section 5. Any person who, for the purpose of evading or assisting in the evasion of any provision of this act shall falsely represent that he is a physician, dentist or veterinarian, or that he is a manufacturer, jobber, wholesale druggist, or pharmacist, or an agent or employee of an incorporated hospital, or who, not being an authorized physician, dentist or veterinarian, makes or alters a prescription for any of the said substances, shall be deemed guilty of a violation of this act.

Section 6. Whoever violates any provision of this act shall be deemed guilty of a misdemeanor, and shall be punished by a fine of not less than fifty nor more than one thousand

dollars, or by imprisonment in the house of correction or jail for a term not exceeding one year, or by both such fine and imprisonment.

Section 7. Chapter two hundred and seventy-one of the acts of the year nineteen hundred and ten is hereby repealed.

Section 8. This act shall take effect on the first day of January, nineteen hundred and fifteen.

#### SOME FACTS OF HISTORICAL AND PRESENT-DAY INTEREST CONCERNING PHARMACEUTICAL INSTITUTIONS.

As already stated, an effort has been made to collect some matters of historical and statistical interest concerning pharmaceutical institutions of learning. The scope of this effort will be recognized from details hereinafter set out. Unfortunately, some institutions failed to respond to several requests for information and, therefore, the work is not complete. Out of the total number of eighty colleges, departments and schools of pharmacy, which, from various sources, were learned to now exist within the United States proper, responses were received from fifty-six. Of this number thirty-nine (39) were reported to be either endowed or to be supported in varying degree by public funds, in one form or another. During the year the Pharmacy Department of the Starling-Ohio Medical College was merged with the College of the Ohio State University. At the close of the college year, the school of pharmacy of the Texas Christian University, of Fort Worth, was discontinued. The various institutions from which responses were received and which, of course, do not include any information from such as have been discontinued from time to time, are shown, collectively, to have had a total of 35,824 graduates since their organization. During the 1914 school year they had 5100 matriculants and 359 special students, making a total of 5459 who were receiving their education at said institutions. The same institutions conferred a total of 1700 degrees at the close of the 1914 college year. An effort was made to separate the various degrees as conferred, depending upon the varying character of study and time, but the different customs and conditions in this connection, made such altogether a hopeless task. However, the total number of graduates as credited for the year have had, at least, a two-year course. It is not out of mind, that out of the total number of graduates, some must have had higher degrees conferred after graduating in pharmacy, but this is not likely to materially effect the total number.

The summary herein before shown, has been compiled from the following information as submitted by the several institutions which have extended kind attention, and matters of general and statistical interest are shown separately as with reference to each, compiled in alphabetical order according to states in which they are respectively located.

*Alabama.* School of Pharmacy, Birmingham Medical College. The college organized in 1894, School of Pharmacy in 1903. Organization largely due to Drs. B. L. Wyman, E. P. Hogan, L. C. Morris, J. D. S. Davis, R. M. Cunningham, B. G. Copeland, F. A. Lupton, J. M. McLester and Park. First regular course of instruction commenced 1903. In the year 1914 had fifty-one matriculants and no special students. In 1914 conferred degrees of Ph. G. (two-year course) upon eighteen; Ph. Ch. (two- or three-year course) upon five; B. S. in Phar. (four-year course) upon one; Phar. D. (one-year graduate work) upon one. Total twenty-five.

*California.* California College of Pharmacy, University of California. Organized in 1872. Organization largely due to James G. Steele, William M. Searby, William Simpson, William T. Wenzell, Winchell Forbes, Dr. H. H. Behr and John Calvert. This institution occupies state premises, and building rent free. First regular course of instructions commenced 1872. Has conferred degrees upon eight hundred seventy. In 1914 had one hundred twenty matriculants

and two special students and conferred degrees of Ph. C. (two-year course) upon forty-three; Phar. B. (three-year course) upon one. Total forty-four.

**College of Pharmacy, University of Southern California.** Organized in 1905. Organization largely due to Walter Taylor, Laird J. Stabler, C. W. Hill. First regular course of instruction commenced in 1905. Has conferred degrees upon one hundred twenty-one since organization. In 1914 had eighty matriculants and conferred degree of Ph. C. (two-year course) upon thirty-five.

**Colorado.** School of Pharmacy of the University of Colorado. Organized in April, 1911. Organization largely due to the activity of Dr. W. P. Harlow, Messrs. W. A. Hoover, E. L. Sholtz and Chas. Ford. First regular course of instructions commenced Sept. 1911. Is supported by legislative appropriation. Has conferred degrees on five persons. For the year 1914 it had twenty matriculants and two special students, and conferred the Degree of Ph. C. (two-year course) upon four, and the Degree of B. S. in Pharmacy (four-year course) upon one.

**District of Columbia.** National College of Pharmacy of George Washington University. Organized in 1872. Affiliated with George Washington University 1906. Organization largely due to J. L. Kidwell, Chas. Stott, Dan'l. B. Clarke, J. P. Milburn, R. B. Ferguson, J. C. Fill, Z. D. Gilman, Jos. W. Nairn, W. S. Thompson, G. G. C. Simms, J. D. O'Donnell, D. P. Hickling, Oscar Oldberg and Frank C. Gaither. Commenced its first regular course in the Fall of that year, and has been continuously operating since that time. Not endowed and not supported by public funds. Has conferred a total of four hundred and fifty-three degrees. For the year 1914, conferred the degree Phar. D. (three-year course) upon eleven. For the year 1914 it had eighty matriculants and sixteen special students.

**Washington, D. C.** Pharmaceutical College of Howard University. Organized March 2, 1867. Organization largely due to Drs. Chas. B. Purvis, Prof. Materia Medica; G. S. Palmer, Prof. Pharmacy; and S. L. Loomis, Prof. Chemistry. First regular course of instruction commenced January 2, 1870. Not endowed and not supported by public funds. Has conferred a total of two hundred forty degrees. For 1914, conferred the degree of Phar. D. (three-year course) upon nine. For the year 1914 it had sixty-two matriculants and one special student.

**Georgia.** University of Georgia, School of Pharmacy. Organized in 1903. Organization largely due to Dr. W. B. Hill, Dr. S. C. Benedict and R. C. Wilson, Ph. G. First regular course of instruction commenced in 1903. Discontinued in 1904 for one year, because of fire. Supported by legislative appropriations principally. Has conferred degrees on thirty-five persons. For the year 1914 had twenty-two regular students. In 1914 conferred the degree of Ph. G. (two-year course, two terms, nine months each) upon seven.

**School of Pharmacy, Mercer University.** Organized 1903. Organization largely due to Prof. J. E. Sellers, Professor of Chemistry at Mercer University, and doctors and druggists of Macon, Ga. First regular course commenced fall of 1903. Supported as a Baptist institution. Has had ninety-six graduates since its organization. In 1914 thirty-nine matriculants and conferred degree of Bachelor of Pharmacy upon ten (two-year course.)

**Illinois.** Northwestern University School of Pharmacy. Organized in 1886. Organization largely due to D. R. Dyche, E. H. Sargent, T. H. Patterson, Wm. Bodenmann, H. S. Maynard and Oscar Oldberg. First regular course of instruction commenced September 3, 1886. Not endowed and not supported by public funds. Has conferred degrees upon approximately, 2050. In 1914 had one hundred twenty-four matriculants and eight special students and conferred degrees upon fifty-seven graduates in Pharmacy and twelve Pharmaceutical Chemists.

**University of Illinois, School of Pharmacy.** Organized in 1859, as the Chicago College of Pharmacy and became a part of the University of Illinois in 1896. Organization largely due to the pharmacists of Chicago, F. Scammon, J. M. Woodworth, F. Mahla, J. D. Payne, S. S. Bliss, W. H. Muller, Geo. Buck, L. F. Humiston, E. O. Gale, F. A. Bryan, E. L. O'Hara and others. First regular course of instruction commenced in November, 1859. No teaching from 1860 to 1870, although the organization, library, museum, etc., were continued. It is supported by state appropriations; last appropriation was \$10,000 annually for two years. Has conferred degrees upon about sixteen hundred. In 1914 had one hundred matriculants and eighty-three special students and conferred degrees on thirty-nine graduates—Ph. C. degree (two-year course) five, Ph. C. (three year course) one, Ph. G. (two-year course) thirty-three.

**Indiana.** Purdue University School of Pharmacy. Organized in 1885. Organization largely due to Drs. Sweet and J. N. Hurty. First regular course of instruction commenced in 1885. Supported by public fund and by tuition. Has conferred degrees upon about eight hundred. In 1914 had fifty-four matriculants and conferred degrees Ph. C. (two year course) sixteen, B. S. degree (four-year course) two.

**Valparaiso University, Department of Pharmacy.** Organized the Institution in 1873, Department in 1892. Organization largely due to Dr. H. M. Evans and Prof. A. E. Hiss. First regular course of instruction commenced in 1892, graduating its first class in August, 1893. Supported by endowment and state funds. Has conferred degrees upon one thousand one hundred and twenty-one. In 1914 had one hundred and forty-three students, about twenty-eight of which were special students, and conferred degrees on forty-five Ph. G. (two-year

course of nine months each) and six Ph. C. (two-year course of twelve months each) graduates.

**Indianapolis College of Pharmacy.** Organized in 1904. Organized as a Department of the Winona Technical Institute. First regular course of instruction commenced in September, 1904. Not endowed or publicly supported. Has conferred degrees upon three hundred. In 1914 had fifty-four matriculants and three special students, and conferred the degree of Ph. G. (two years required, twenty-six and thirty-six weeks each) upon twenty-two. Ph. C. (two-year course, twenty-six and thirty-six weeks each) upon four.

**Iowa.** The College of Pharmacy of the State University of Iowa. Organized in 1885. Organization largely due to J. H. Harrison, Davenport, Iowa; Geo. H. Schafer, Ft. Madison, Iowa; E. L. Boemer, Iowa City, Iowa. First regular course of instruction commenced September, 1885. Supported by the State of Iowa, being a part of the State University of Iowa. Has conferred degrees upon three hundred seventeen. In the year 1914 had sixty-seven students, and conferred Ph. G. degree (two-year course) upon fourteen. Ph. C. degree (three-year course) upon three.

**Highland Park College of Phar., Highland Park College.** Organized in 1891. Organization largely due to Dr. O. H. Longwell and Dr. S. R. Macy. Is controlled by Presbyterian Church and supported to the extent of \$200,000 by public since taken over. Was self-supporting before that time. First regular course of instruction commenced in September, 1891. Has conferred degrees upon about one thousand one hundred, many more having taken work. In 1914 had sixty matriculants and thirty-five special students and conferred degrees Ph. G. (two years; twenty-five weeks) upon fourteen Ph. C. (two years, thirty-six weeks course) upon nine.

**Kentucky.** Louisville College of Pharmacy. Organized August 16, 1870. Organization largely due to C. Lewis Diehl, John Colgan, Geo. A. Newman, F. J. Pflugst, H. H. Rademaker, C. Tafel, Geo. Zubrod, Arthur Peter, Graham Wilder, Floyd Parks, etc. First regular course of instruction commenced in 1871. Not endowed and not publicly supported. Has conferred degrees upon six hundred eleven graduates, 1914 inclusive. For the year 1914 had eighty-three matriculants and conferred Ph. D. degree (two-year course) upon twenty-nine.

**Louisiana.** New Orleans College of Pharmacy. Organized 1900. Organization largely due to F. C. Godbold, M. T. Breslin, W. T. Taylor and Phillip Asher. First regular course commenced November 5, 1900. Not endowed and is not publicly supported. Has conferred degrees upon two hundred sixty-seven. For the year 1914 had eighty-one regular and two special students and conferred degrees of Ph. G. (two-year course) upon twenty.

**New Orleans.** School of Pharmacy, College of Medicine, Tulane University of Louisiana. Organized 1838. First regular course commenced 1838. Was discontinued during the Civil War, 1862-65. Shares the endowment of School and College of Medicine, \$1,000,000. Has conferred four hundred and twenty-eight degrees. For the year 1914 had seven students, and conferred Ph. C. degree (two-year course) upon three.

**Flint Medical College, Department of New Orleans University.** Was organized in 1900. Organization largely due to Dr. Clements. First regular course commenced 1900. The Medical College, of which the Pharmacy School was formerly a part, had a \$10,000 endowment. Has conferred fifty-nine degrees. For the year 1914 had twenty-six regular students, and conferred Ph. G. degree (two-year course, eight months each) upon eight.

**Maryland.** Department of Pharmacy, University of Maryland (Maryland College of Pharmacy, 1841-1904.) Organized 1840. Incorporated 1841. Organization largely due to Drs. Samuel G. Baker, W. E. A. Aikin, William Riley; Pharmacists, Thomas G. Mackenzie, Geo. W. Andrews, David Stewart, Robt. H. Coleman, B. H. Atkinson, John Hill, Jonathan Chapman and J. W. M. Gordan. First regular course commenced November, 1841. Discontinued 1847 to 1856, because of the few students and lack of interest in the college on the part of pharmacists. Not endowed or publicly supported. Has conferred one thousand sixty-one degrees. For the year 1914 had seventy-three regular students and three special students, and conferred twenty-four degrees of Ph. D. (two-year course.)

**Massachusetts.** Massachusetts College of Pharmacy. Organized in 1823. First regular course of instruction commenced in 1867. Is endowed with about \$240,000. Has conferred about eight hundred and ninety degrees. In the year 1914 had two hundred and twelve regular students and twenty-six special students, and had thirty-two graduates in pharmacy (two-year course) and seven pharmaceutical chemists (three-year course.)

**Michigan.** School of Pharmacy, University of Michigan. Organized 1868. Organization largely due to Dr. Albert B. Prescott. First regular course commenced October, 1868. Is supported entirely by the state. Has conferred one thousand one hundred and seventeen degrees. In 1914 had ninety-eight regular students and nine special students, and conferred B. S. degree (four-year course) upon three; Ph. C. degree (two-year course) upon twelve. Owing to change in the course, the number of graduates was less than usual.

**Minnesota.** College of Pharmacy of the University of Minnesota. Organized in 1892. Organization largely due to the Minnesota State Pharmaceutical Association and the University of Minnesota Board of Regents. First regular course commenced in 1892. Not endowed but received recent legislative and other appropriations to the amount of \$109,000,

used for the erection of fireproof new pharmacy building. Has conferred three hundred and forty-four degrees. In 1914 had ninety-nine students, and conferred Ph. M. degree (four-year course) upon two. Ph. B. degree (two and three-year courses) upon twenty-eight.

*Missouri.* Kansas City College of Pharmacy and Natural Sciences. Organized 1884, re-organized 1898. Organization largely due to S. Emery Lamphear, A. M., M. D., Randall R. Hunter, M. D., Julius G. Kiefer, M. D., Ph. G., Thos. J. Eaton, M. D. First regular course commenced 1887-1888. Not endowed and not supported by public funds. Has conferred four hundred and forty-three degrees. In 1914 had forty-seven regular students and eight special students and conferred Ph. G. degree (two terms of eight months each, four years experience) upon fifteen. Ph. B. degree (two terms of eight months each, two years experience) upon three.

St. Louis. School of Pharmacy, National University. Organized 1904. Organization largely due to Barnes Medical College. Was re-organized by National University and the name changed 1912. First regular course of instruction commenced 1904, as Barnes College. Not endowed. Has conferred one hundred fifty degrees since organization. In 1914 had twenty-eight regular students and two special students, and conferred Ph. G. degree upon seven; Ph. C. upon one, and one special with no degree.

*Montana.* University of Montana, School of Pharmacy. Organized 1907 in connection with the state agricultural college and transferred July, 1913, to the University at Missoula. Organization largely due to state board of education. Is supported by state funds and from moneys from State Land Grants. First regular course of instructions commenced in September, 1907. In 1914 had thirteen matriculants and two special students, and conferred the degree of Ph. C. (three-year course) upon one. Has conferred fourteen degrees since organization.

*Nebraska.* Creighton University, College of Pharmacy, Omaha. Organized September 1, 1905. Organization largely due to board of trustees. First regular course commenced September 1, 1905. University has sufficient endowment. Has conferred about three hundred forty degrees. In the year 1914 had as students: Seniors, seventy-five, one special; juniors sixty-six, regulars, three specials, and conferred Ph. G. degree (two-year course) upon sixty-two.

School of Pharmacy, University of Nebraska. Organized in 1908. Organization largely due to E. Benj. Andrews, Chancellor Rufus A. Lyman, Henry B. Ward, Samuel Avery and Chas. F. Beasy. First regular course commenced in September, 1908. Supported by taxation, approximately \$20,000 per year. Has conferred about thirty-seven degrees. In the year 1914 had thirty-seven regular students and two special students, and conferred degrees on eleven students. B. Sc. (four-year course) upon two. Ph. C. degree (three-year course) upon two. Ph. G. degree (two-year course) upon seven.

*New Jersey.* Department of Pharmacy, College of Jersey City, (formerly University of the State of New Jersey.) Organized in 1908. Organization largely due to pharmacists, physicians and business men of Jersey City and New York. First regular course commenced in 1908. Has conferred Ph. G. degree upon eighty-two and Phar. D. upon fifty-nine since organization. In the year 1914 had ninety-nine regular students and one special student and conferred Ph. G. degree (two-year course) upon sixteen; Phar. D. (three-year course) upon thirty-five.

*New York.* Albany College of Pharmacy, Department of Pharmacy, Union University. Organized in the year 1881. Organization largely due to Willis G. Tucker, M. D.; Jacob S. Mosher, M. D.; and Gustavus Michaelis. First regular course of instruction commenced October, 1881. Has conferred seven hundred and forty degrees since organization. In 1914 had one hundred and ten regular students and five special students, and conferred degree of Ph. G. (two-year course) upon forty-one.

Brooklyn College of Pharmacy. Organized in 1886. Organization largely due to the Kings County Pharmaceutical Society. First regular course of instruction commenced in 1890. Has conferred Ph. G. degree to one thousand three hundred and forty-two students and Phar. D. degree to one hundred and forty-six since organization. In 1914 had three hundred regular students and conferred Ph. G. degree (two-year course) upon one hundred and ten and Phar. D. degree (three-year course) upon twenty-nine, making a total of one hundred and thirty-nine.

Buffalo College of Pharmacy (By permission, legal title, Department of Pharmacy, University of Buffalo.) Organized in 1886. Organization largely due to Dr. Matthew D. Mann, (McKinley's surgeon, Pres. William, chemist). First regular course of instruction commenced September, 1886. Has conferred degrees upon eight hundred and twenty-one since organization. In 1914 had one hundred and thirty-two pharmacists, forty chemists, and six special students, and conferred degrees upon fifty-six graduates in Phar., (Ph. G.) and fourteen in Pharm. B. Science, (A. C. C.).

College of Pharmacy of the City of New York, Columbia University. Organized 1829. Organization largely due to Messrs. John D. Koese, Henry H. Schiffelin, Constantine Adamson, John F. Embree, and many others. First regular course commenced in 1829. Has conferred degrees to four thousand and ninety-four pharmacists. In 1914 had five hundred and fourteen students and conferred degree of Ph. G. (two-year course) upon one hundred and

thirty-six; Ph. Ch. (two-year course, course now three years) upon twenty; Phar. D. upon six and upon Food and Drug Analysts, two.

Fordham University, College of Pharmacy, New York City. Organized in 1911. Organization largely due to Rev. Father Thos. J. McClusky, president of university. Dr. J. J. Sheridan, registrar, and Dr. Jacob Diner, pro-dean. First regular course commenced September, 1911. Has conferred degrees upon seven since organization. In 1914 had thirty-eight regular students and seven special students and conferred degree of Ph. G. (two-year course) upon seven.

*North Carolina.* Leonard School of Pharmacy, Raleigh, N. C. Organized in 1890. Organization largely due to Henry Martin Tupper. First regular course commenced November 2, 1891. Has conferred degrees upon one hundred and nine since organization. In 1914 had twenty-seven students and conferred Ph. G. degree upon two.

School of Pharmacy, University of North Carolina. Organized in 1897. Organization largely due to Dr. F. P. Venable, Chapel Hill; Pres. E. A. Alderman, now president University of Virginia. It is supported by University. First regular course of instructions commenced September, 1907. Has conferred degrees upon, approximately, one hundred and fifty since organization. In 1914 had forty-eight matriculants and eight special students and conferred degree of Ph. G. (two-year course of nine months each) upon four.

*North Dakota.* School of Pharmacy, North Dakota Agricultural College. Organized 1902. Organization largely due to the druggists of the state and to E. F. Ladd. First regular course commenced in the fall of 1902. Supported by land endowment fund, national appropriation and state appropriation. Has had forty-three graduates and some three hundred students not graduates. In 1914 had twenty-nine regular students and conferred degrees of Ph. G. (two-year course) upon five and B. S. (four-year course) upon one.

*Ohio.* Ohio Northern University, College of Pharmacy. Organized in 1885. Organization largely due to President H. L. Lehr. Is supported in part, by a \$200,000 endowment. First regular course commenced in the fall of 1885 and has had about one thousand and one hundred graduates. In 1914 had ninety-six regular students and conferred degree of Pharm. Grad. upon thirty-three, course requiring two years of thirty-two weeks each.

College of Pharmacy, Ohio State University. Organized in 1885. Organization largely due to Professor Sidney A. Norton and Professor Geo. B. Kauffman. Is supported by funds appropriated to the university and then set apart for the college. First regular course commenced September, 1885. Has conferred degrees upon about two hundred and ninety-five. In 1914 had ninety-five regular students and ten special students and conferred degrees of B. Sc. in Pharmacy (four-year course) upon six; certificate, Ph. C. (two-year course) upon seventeen.

Cincinnati College of Pharmacy. Organized March, 1850. Organization largely due to Wm. S. Gordon, Jas. M. Ayers and C. Smith. Was discontinued during Civil War. Messrs. E. S. Wayne, Wm. B. Chapman and A. Fennel being instrumental in its re-organization. Mutual interchange of knowledge and discussions commenced in 1850. Has conferred fully one thousand degrees since organization. In 1914 had forty-two regular students and conferred degree of Ph. B. (twelve hundred-hour course) upon thirty and degree of Ph. C. (seventeen hundred-hour course) upon two.

*Oregon.* North Pacific College of Pharmacy, a department of North Pacific College. Organized in 1907. Organization largely due to Dr. Herbert C. Miller. Department is supported by North Pacific College. First regular course commenced in 1908. Has conferred forty-three degrees since organization. In 1914 had twenty-eight regular students and eleven graduates received Ph. G. degree (two-year course.)

Oregon Agricultural College, Department of Pharmacy. Organized in 1899. Is supported by state and federal funds. First regular course commenced in September, 1899. Has conferred degrees upon seventy-eight with B. S. degree. In 1914 had sixty-nine regular students, conferred B. S. degree (four-year course) upon four and had three graduates from two-year course.

*Pennsylvania.* Medico Chirurgical College, Department of Pharmacy and Chemistry, Philadelphia, Pa. Organized in 1898. Organization largely due to Dr. John V. Shoemaker, Dr. Geo. H. Meeker, the board of trustees and medical faculty of the Medico Chi. College. First regular course commenced in September, 1898. Has conferred degrees upon about seven hundred graduates. In 1914 had one hundred and sixty-four regular students and conferred degree of Phar. D. (four-year course) upon three; Ph. C. degree (three-year course) upon twelve; Ph. G. degree (two-year course) upon forty. Total fifty-five.

Pittsburg College of Pharmacy, School of Pharmacy, University of Pittsburg. Organized in 1878. Organization largely due to Messrs. W. G. Schirmer, Louis Emanuel and J. B. Cherry. First regular course commenced on October 1, 1878. Has conferred degrees upon about one thousand six hundred. In 1914 had two hundred twenty regular students, and three special students and conferred degrees of Ph. G. (two-year course) upon eighty; Ph. C. (three-year course) upon one; Phar. D. (three-year course) upon five; Certificate of Proficiency (two-year course) upon two.

Philadelphia College of Pharmacy. Organized in 1821 by druggists of the city and districts. Incorporated, 1822. First regular course commenced in 1821. Has conferred degrees upon six thousand, three hundred sixty-three. In 1914 had four hundred eighteen regular

students and forty-nine special students and conferred degrees of P. D. (three-year course) upon one hundred five; P. C. (three-year course) upon eleven; six certificates of Proficiency in Chemistry (three-year course); one certificate of Proficiency in Food and Drugs (two-year course); twenty-three certificates in Bacteriology (ten-weeks course.)

*South Carolina.* Medical College of the State of South Carolina, School of Pharmacy. Organized in 1882. Discontinued in 1884 and resumed in 1894, and has continued in operation since. First regular course commenced in 1882. The college being owned by the state this school in conjunction with the school of medicine, supported by the state. Has conferred three hundred twenty-two degrees. In 1914 had forty-three regular students and conferred degree Ph. G. (two-year course) upon twenty-one.

*Tennessee.* Department of Pharmacy, Vanderbilt University. Organized in 1879. Organization largely due to Bishop McTycire, President Board of Trustees, Chancellor Garland. First regular course commenced in 1879. No endowment or public funds, other than those of the university. Has conferred approximately three hundred fifty degrees since organization. In 1914 had forty regular students and conferred degrees of Ph. D. upon seven and Ph. C. upon three.

University of Tennessee, School of Pharmacy. Organized in 1898 as an integral department of the state university and maintained for the first twelve years with the seven other departments in Knoxville, Tenn. First regular course commenced in 1898. Removed from Knoxville to Memphis 1911, where it has since absorbed the University of Memphis, College of Pharmacy. Integral part of the state university supported by appropriation from the state. Has conferred degrees upon sixty-two since organization. In 1914 had sixteen regular students and conferred degrees of Ph. C. upon ten; the two-year course hereafter leads to Ph. G. certificate. The three-year course to the Ph. C. degree.

Mcharry Pharmaceutical College, Walden University. Organized 1889. Organization largely due to Mcharry Family, Rev. J. Branden and G. W. Hubbard, M. D. Not endowed and no public funds. First course commenced October 7, 1889. Has had two hundred six graduates. In the year 1911 had fifty-two regular students and conferred degree of Ph. C. upon eight.

*Texas.* School of Pharmacy, Medical Department, Texas Christian University. Organized in 1905. Organization largely due to M. H. Gilmore, Ph. C., M. D., Fort Worth, Texas; R. W. Needham, Ph. C., Fort Worth, Texas. First course commenced October 10, 1905. Has conferred degrees upon sixty-one since organization. In 1914 had fourteen regular students and two special students and conferred degrees upon six graduates in Phar. (two-year course)

*Virginia.* School of Phar., Medical College of Virginia. (Result of Amalgamation of Virginia School of Phar. and Department of Pharmacy, University College of Medicine in July, 1913.) Organized 1893. Both schools forming the merged institution, were organized through their board of trustees. First regular course commenced in 1893. The Medical College of Virginia, of which School of Phar. is a part, receives \$5000 annually from the state. The total number of degrees conferred from both schools forming merger is about five hundred. In 1911 it had sixty-six regular students and five special students, and degrees of Ph. G. was conferred upon twenty-five graduates (two-year course, eight months each.)

*Washington.* University of Washington College of Phar., Seattle. Organized in 1894. Is supported as a department of the university by a mill-tax. First regular course commenced fall of 1894. Has conferred degrees upon about one hundred fifty since organization. In 1914 had eighty-one regular students and conferred degree of Ph. C. (two-year course) upon thirteen and degree of B. S. (four-year course) upon six.

State College of Washington. Organized in 1896 when Department of Pharmacy was added. Organization largely due to the members of state legislature. Supported by state and federal funds as a part of the state agricultural college. First regular course commenced in 1896. Has conferred degrees upon one hundred sixty since organization. In 1914 had thirty regular students and conferred Ph. G. degree (two-year course) upon ten; B. Sc. degree (four-year course) upon one.

*Wisconsin.* University of Wisconsin Course in Pharmacy. Organized in 1883. Organization largely due to Wisconsin Pharmaceutical Association. Is supported by legislative appropriation. First regular course commenced in 1883. Has conferred degrees upon three hundred twenty-eight since organization. In 1914 had thirty-nine regular students, and one special student and conferred Ph. G. degree (two-year course) upon seven and B. S. degree (four year course) upon five.

Marquette University, School of Pharmacy. Organized 1893 as private school, 1900 as a department of the Milwaukee Medical College, 1907 as a department of Marquette. Organization largely due to R. F. W. Sommer, Ph. D. Is supported by university funds. Up to 1900 it merely gave "quiz" courses. After that date it gave regular courses leading to degrees. Has conferred degrees upon one hundred ninety since organization. In 1914 had fifty regular students, and twenty four special students and conferred degree Ph. G. (two-year course) upon twenty one and Ph. C. degree (three year course) upon three.

Respectfully submitted,

FRANK H. FREEBICKS,  
Secretary.

COMPARATIVE REAL AND PERMANENT BENEFIT TO THE  
STUDENT OF LECTURES AND LABORATORY PRACTICE.

---

W. B. DAY, PH. G.

---

I would certainly not have ventured upon the preparation of a paper covering so broad a field, were it not for the assurance of our chairman, at whose request this paper was prepared, that it would be intended simply as a basis for discussion and that the subject would be restricted to the student of pharmacy. Had the choice been left to me, I think I should have elected as a subject, "Some Thoughts on Teaching," and the discussion then might have become an "experience meeting!"

At the outset, we may safely assume that there is no difference of opinion among pharmaceutical teachers in regard to the great importance—even the absolute necessity of laboratory courses. Few would assign an *inferior* position to laboratory instruction in valuing the *curriculum* of the pharmaceutical school.

The chief object of teaching is to train the mind to clear thinking,—the power to forecast what will happen under given conditions. The imparting of information, however necessary or desirable, especially to the professional or technical student, must nevertheless be regarded as of secondary importance.

Laboratory-practise best gives the training which enables the learner to successfully attack new problems, hence its immediate bearing upon actual life, where new problems and new conditions are constantly being presented.

In the laboratory the student learns from his mistakes, and with less serious consequences than in after life. In lecture courses, on the other hand, the lecturer presents information which has, perhaps, cost years of study and preparation and sets this forth in attractive form with demonstrations and explanations such as clarify the subject in hand and make it as simple and as easily grasped as its nature permits. The interest of the learner is aroused, his enthusiasm grows, reference reading is suggested, he is led to a sincere desire to know, which is the hall-mark of the real student.

The dangers of the lecture system arise from this very ease by which information is imbibed. We are all apt to underrate what is easily attained, the surmounting of obstacles, the courage and will-power growing out of effort and the joy of achievement gained over difficulties, are largely lost.

Yet, we must not forget that the instruction in our schools of pharmacy, until within a few decades, consisted exclusively of lectures; and by means of this instruction or through it, many pharmacists of superior professional attainments were developed. If you reply that the drug-store training afforded in those times a more acceptable substitute for laboratory-practise than it does at present, I grant the truth of your argument, but not its sufficiency. No one can say which form of discipline is best in every case. So much depends upon the teacher and not less upon the student. Garfield's definition of a university was, "Mark Hopkins on one end of a log and a student on the other."

We may be sure that when we fail to interest, we fail to educate. The first requisite to success in teaching, is the ability to create or to awaken this desire

to learn. But to interest, does not mean to amuse, though some pupils seem to incline to this view. A former associate of mine could never escape the feeling that a considerable number of his pupils regarded the carefully prepared and exceedingly interesting experiments, with which he illustrated his lectures in chemistry, as a sort of vaudeville performance.

Unfortunately, many students in schools of pharmacy are studying, not primarily to equip themselves for their life-work, but rather to attain some object which should be of secondary importance—to pass the state examination for license or to secure just sufficient credits to obtain a diploma. Seldom does a class distinguish itself by showing a general interest in the studies all along the line.

One reason for lack of interest by pharmaceutical students, is the opinion held by some pharmacists that success in college does not especially fit the student for a successful career. Occasionally this view has been impressed upon otherwise bright and capable young men, and results in an attitude of cynicism and indifference not easily overcome.

Again, a small proportion of the student-body seem to hold the opinion that when their fees are paid, the teachers should do the rest. They seem to take seriously the words which Mr. Dooley wittily puts in the mouth of the college president who asks the incoming freshman: "What branch iv learnin' wud ye like to have studied f'r ye be our compitint professors?"

But how much want of real interest is due to causes outside the student, to prosy and uninteresting lectures, to a routine of carelessly-supervised laboratory operations and to dry and formal text-book recitations, which undertake to force set tasks on reluctant youth?

The problems we encounter here will not be solved by sitting down and thinking about them. More intimate and personal contact between teacher and pupil, so that each may better acquire the viewpoint of the other, will be of great help. This implies smaller classes or at least smaller groups and more carefully inspected, more closely checked, work, it means more time from both teacher and student.

Rigorous exclusion of incompetent and idle students early in the course will aid wonderfully. As President Nichols of Dartmouth said, "It is difficult to conduct a college which shall be at once an effective training-school for studious men and an infirmary for the treatment of mental apathy."

However, I believe that students of pharmacy, as a class, will compare favorably with other college students. The great majority attend school to learn, even if their ambitions are too easily satisfied. Students who seek social advantages, or who are interested chiefly in athletics, or whose sole aim is to have "a good time" are not likely to select the schools of pharmacy. With the increasing requirements for entrance, a further improvement in the *morale* of the student body may be confidently expected.

Thanks largely to the growing appreciation by educators generally, of the advantages of concrete methods over the memory-cramming system which has so long held sway in our elementary schools, I believe that our students are better fitted now than formerly, to appreciate the advantages afforded by the

laboratory and are less likely to consider its work as made up of "stunts" which have little connection with the general course.

And,—to return to our subject,—from which method of instruction, lectures or laboratory-practise, does the student benefit most? I answer, it depends on the teacher and on the student. But, in general, I think you will agree with me, that lectures which most closely approach the laboratory method, namely those which freely employ demonstration and experiment, are the most efficient, while laboratory-practise which shares some of the lecture methods, if indeed it does not directly accompany or follow a lecture, gives also the best results.

To my mind, the ideal plan is the combination of lectures, recitations and laboratory-practise associated together in each subject and with the teacher allowed much latitude in the assignment of the relative number of hours devoted to each of these means of instruction. I believe that when the present minimum course adopted by our syllabus committee is increased, the hours added should be very largely given to laboratory-practise.

And let us keep in mind the changed conditions now confronting students of pharmacy and anticipate, as we can, the further changes which are near at hand. As Professor Mann has put it aptly, concerning the student in another branch of education, "It is no longer, What does he know?—but, What can he do? No longer, How much can he reproduce?—but, How well can he produce?"

*University of Illinois School of Pharmacy.*

---

## THE COMPARATIVE ADVANTAGES OF PRACTICAL EXPERIENCE AND GENERAL EDUCATION AS A PRE-REQUISITE OF INSTRUCTION IN A SCHOOL OF PHARMACY.

---

DR. HENRY H. RUSBY.

---

If the pharmacist were a machine, possessing no other intelligence than that which represented the maker, and doing his work as a result of having been wound up and set going, it would appear desirable to leave out of his construction every unnecessary cog and rivet, lever and spring, so that he would do nothing else than go through the motions for which he was constructed, and would know nothing about what he was doing or why he was doing it. To approach, as nearly as it is possible for a human being to do, to this condition appears to be the conception of the pharmacist's duty which is entertained by a large number of persons connected with the calling. Being a human soul, the real duty of the pharmacist would appear to be to escape just as far from the state suggested, as is consistent with his professional work. The thoughtful person will not fail to recall, that, even in the performance of his ordinary duties, the pharmacist is as often called upon to meet emergencies, and to be thrown upon the resources of his individual intelligence, as are most other members of the community. He will best do this, whose ideas and whose judgment have been the most broadened, and whose intellect has been the most developed;

strictly professional knowledge and skill being not considered. My claim, therefore, as to the value and importance of the preparatory general education of the pharmacy student, is a double one: first, that his professional work is not the *end* of his living, but merely a *means* to the end of that individual development, which he shares with all other members of society, and for the promotion of which he is entitled to a liberal preparatory education. Second, that such a preparatory education is necessary to give him the intellectual capacity that his professional work requires.

On the other hand, practical professional training is indispensable, and the earlier that a student gets it, the better will be his preparation. To attempt to compare the value and importance of these two elements in his preparation, is, therefore, like comparing the relative importance of food and drink in the human diet. Since both are essential, it becomes a question, not of their relative importance, but of the appropriate division of time between them and the most opportune period of its assignment. It must be remembered that there is but one time when the pharmacist can secure any systematic general education, and that is before he begins his professional course of study. From the day of the opening of his pharmacy course, until the day of his professional retirement on a competence, should he be so fortunate, his studies will become more and more narrowly professional. In the first year of his pharmacy course, there will be some latitude in the direction of a broad theoretical foundation for his studies, but in the second, his attention is to be restricted to purely technical matters. As soon as he graduates, the life and death struggle with finance, will begin to absorb him. Having decided then, how much general education he should receive, there appears to be no choice as to the place of its assignment; it must come before he matriculates in the pharmacy school, except for the slight theoretical teaching of the introductory year. Practical training on the other hand begins with matriculation, increases in the second year and becomes the exclusive occupation after graduation.

The question now arises as to the desirability of beginning this practical training earlier and of excising, in its interest, a part of the scanty general education that can come only in the ante-pharmacy period of life. It is frequently said, and truthfully so, that a boy who has a year in a store, before he attends college, makes a better pharmacy student than one who does not. It is equally true that, if he never attended primary, grammar or high school at all, but went to work in the drug store as soon as he was capable of performing any duties, he would do still better with his strictly professional work in the pharmacy school. Indeed, he would probably not have to attend that school at all, in order to be able to pass the ordinary board examination. Now, would that fact constitute a justification for instituting such an arrangement?

As a matter of fact, it makes a boy a still better student and a much better pharmacist, if he can take a year of store work between his first and second years of school work, and this arrangement is far less open to objection than the other. Far better than either, is the plan of combining the two kinds of work in a single course, as is done in our larger cities. Given a sufficiently extended course of study,—which a two-year course is not,—and the alternate days of school work

in store experience, with long vacations devoted also to store experience, is the ideal way for gaining practical experience, and this arrangement entirely eliminates the grounds for demanding practical training before the school course begins.

---

## THE NEED FOR ENFORCING EXISTING LAWS.

---

BY M. I. WILBERT, PH. D.

---

If one were to be influenced solely by the evidence presented in the printed proceedings of the state pharmaceutical associations and in the pages of trade-journals one would be justified in the conclusion that the great American mania for law-making is more frequently evidenced in the followers of our craft than in the votaries of any other occupation.

There are, of course, good and sufficient reasons for the periodic interest on the part of members of the drug trade in legislative matters, not the least important of which is the fact, that the drug business offers such a variety of possibilities for the activities of well-meaning but usually poorly-informed reformers; which from a very early period has offered a fruitful field for so-called reform legislation, with all of the inconsistencies and inconveniences that are usually entailed.

It should be remembered though, that many of the existing laws, had their origin with well-meaning, though not always far-seeing members, of the pharmaceutical craft, who were really desirous of accomplishing something of value for the purpose of protecting the interests of the public, and that we of to-day are loath to have their work undone. These early advocates of statutory laws and we, their followers, frequently fail in our legislative program because we lose sight of the essential truth that, without strong public opinion to insist on their enforcement, statute laws are of necessity in-operative.

General arguments, however, are not always convincing and for the purpose in hand it may perhaps be best to restrict the discussion to specific instances.

The Pharmacopœia itself is now so thoroughly well established as an essential feature of the statutes relating to the drug trade, that no argument would appear to be necessary to convince members of our craft that the requirements of the pharmacopœia are *in fact* law and should be lived up to by all members of the trade entrusted with the important duty of controlling the nature and purity of drugs dispensed to the consumer.

In recent years, we have heard many and at times apparently reasonable arguments, in favor of the elimination of that feature of Section 7. of the Food and Drugs Act, which permits of variations from pharmacopœial strength, providing the variation be plainly stated upon the bottle, box or other container. The need for, or even the desirability of, such a change is open to question, when one considers that food and drugs laws are now generally well-recognized as being measures to compel commercial honesty and, strictly and impartially enforced along the lines suggested in recent court decisions, these laws will go

far toward accomplishing even more good than was expected of them by their original promoters. The enforcement of these laws, however, must be consistent and include the practices in all branches of the trade.

The futility of amending Section 7., referred to above, at the present time, without first adequately safeguarding the very foundation of the drug business, *the final distribution to the consumer*, will be apparent when one considers the reports of officials entrusted with the enforcement of pure drugs laws and of laws designed to regulate weights and measures.

The reports from the former sources are fairly well reflected in recent numbers of Hygienic Laboratory Bulletins containing the compilations entitled, "Digest of Comments on the Pharmacopœia and National Formulary." A recent compilation of some of this data (Public Health Reports, 1914, v. 29, p. 1137) shows that of 10,524 samples of twenty-six official articles reported on, no less than 3,288 or thirty-one and two-tenths per cent. were not in compliance with the official requirements.

The one important factor in the non-compliance of these articles, is carelessness, criminal carelessness, on the part of persons entrusted by law to dispense medicines to the consumer.

How fundamentally careless retail druggists really are becomes evident when we learn that in a comparatively recent report from the State of Kansas, it was stated that nearly one-half of the prescription weights examined were condemned and that of 718 prescription scales examined, 195 were found to be unfit for use.

In an address before the National Conference on Weights and Measures, held at Washington, in 1914, F. P. Downing, the Chief Inspector of Weights and Measures, asserted that the coin-weights used in the delicate weighing-apparatus in drug stores, were often found to be ten to thirty per cent. light, and that, in a recent inspection in the city of Milwaukee, twenty-two and one-tenth per cent. of dispensing scales and forty-three and six-tenths per cent. of the dispensing weights in use were found in error.

An even more serious arraignment of dispensing store practices, is contained in a report by George B. Taylor to the Louisiana Board of Health. A prescription calling for two grains of boric acid and two ounces of distilled water was filled by sixty-eight New Orleans druggists. Of these only twenty-two, or thirty-two and three-tenths per cent. were correct both as to distilled water and to weight; considerable allowance being given in weight. Seventeen, or twenty-five per cent., were correct as to weight, but not as to the use of distilled water; fourteen, or twenty-six and six-tenths per cent. were correct as to the use of distilled water but incorrect in weight and fifteen, or twenty-two and one-tenth per cent. were incorrect both as to the use of distilled water and as to weight.

These instances could, of course, be duplicated many times over, but enough has been said to emphasize the point I desire to make, that a very marked improvement, in the nature of the control exercised in the distribution of drugs to the consumer, should be made, and must be made, if the pharmacopœia is to be continued as a recognized book of standards. It goes without saying that quite regardless of the purity or kind of drugs purchased or sold by the manufacturer, unless they are adequately controlled and accurately dispensed, the consumer cannot possibly derive any benefit from the laws designed to compel

commercial honesty so far as drug products are concerned. The second point I wish to make, is the need for enforcing existing laws designed to restrict the sale and use of poisons. This need is being emphasized in connection with corrosive mercuric chloride, particularly the tablets of this substance which have had more than their share of attention during the past year. For a period of nearly a year, persons in touch with newspaper work took it upon themselves to institute an altogether unwarranted agitation for legislation to prevent something that in reality did not exist.

In not a few instances, even pharmacists were carried away with the newspaper clatter for specific legislation to control the sale of so-called "antiseptic tablets," apparently quite oblivious of the fact that they, themselves, were constantly violating existing statute laws that, in themselves, would be quite sufficient to control the traffic if *honestly* enforced. Practically, all of the existing poison-laws, either directly or by inference, require that the seller satisfy himself above all, that the article is to be used for a legitimate purpose. It is generally recognized, that a very large proportion of the so-called "antiseptic tablets" sold in this country, are not used and are not designed to be used, for legitimate purposes and to this extent the drug trade of the country has been negligent of its duty in safeguarding the best interests of the public. Apart, however, from this particular phase of the subject, it is interesting to learn that the agitation for safeguarding the sale of tablets of corrosive mercuric chloride, because of possible accidental poisoning was, and still is, absolutely unwarranted. Unfortunately, reliable statistics recording cases of poisoning in this country are not readily available, so that the figures are not as startling as they would be were more complete reports available.

For six months, from October, 1913, to March, 1914, I made an effort to compile, from newspaper-clippings, all of the reported cases of corrosive mercuric chloride poisoning in the city of Washington. This compilation of newspaper-clippings, aggregating several hundred, some of them long and harrowing accounts of meaningless details, when analyzed, show a total of twenty-one cases, five males and sixteen females. Of the five males, two fatal cases were acknowledged suicides, one non-fatal case was uncertain and two children, both under two years of age, were found playing with tablets of corrosive mercuric chloride but had probably not taken any of the drug, certainly not a sufficient amount to injure them in any way. Of the sixteen females, four cases were fatal and were undoubtedly cases of suicide, nine were not fatal and in three cases the final outcome is unknown but the patients probably recovered. Summing up the intent, as evidenced by the newspaper reports, we find that the six fatal cases of poisoning were intentional or deliberate suicide; ten of the remaining cases had evidently taken the poison with suicidal intent and in three cases, including the two cases of supposed poisoning in children, the ingestion, if ingestion there was, was due to rank carelessness on the part of some other person and in two additional cases the intent was not apparent, or, as seemed more probable, the cases themselves were "faked" either by the patients or the newspaper reporters.

Somewhat more illuminating data can be obtained from a comparative study of the annual report of the Registrar-General for England and Wales. This

report for 1911 was for a total of 36,070,492 people and the specific cases of poisoning from corrosive mercuric chloride in that year, included five suicides and two cases of accidental poisoning. The report for 1912, just published, includes ten suicides and three cases of accidental poisoning.

The comparative effect of newspaper notoriety on the use of a substance for suicidal purposes, is well shown by a compilation from the annual reports by the coroner of the city of St. Louis, secured by Mr. Francis Hemm, who has kindly furnished the figures. The annual report covers the period from April 1st to March 31st, 1913-1914, which includes practically the time during which much of the unwarranted publicity was given to cases of poisoning by corrosive mercuric chloride in the newspapers of this country. Taking the figures for five years we find that the number of cases of accidental poisoning from the use of corrosive mercuric chloride in St. Louis, a city of 687,027 people in 1910, were three, viz.:— 1910, 0; 1911, 1; 1912, 1; 1913, 1; 1914, 0. The number of suicides from the use of corrosive mercuric chloride during the same period was twenty-one, viz.:— 1910, 1; 1911, 1; 1912, 4; 1913, 3; 1914, 12. It will be seen that the marked increase during the years 1913-1914, is out of all proportion to what might have been expected normally, and plainly shows the suggestive effect of newspaper publicity. Compared with the population of England and Wales, the rate reported in St. Louis would aggregate a total of more than 600 cases of poisoning from corrosive mercuric chloride alone.

In connection with the corrosive sublimate agitation, we, as pharmacists, are doubly to blame, first, in not living up to existing laws or in not compelling our competitors to comply with the law, and, secondly, in not directing the attention of newspapers, in language sufficiently convincing, to the fact that suggestive material in the way of details regarding the use of a poison or of any other agency for the destruction of human life, is unwarranted publicity, and, at best, offers an unnecessary incentive to the morbidly inclined to use the suggested method of self-destruction.

Finally, a word on narcotic legislation and the tremendous misuse and abuse of drugs of this kind. Practically every State in the Union at the present time has on its statute books a reasonably efficient anti-narcotic law which if it were not such an absolutely dead-letter would serve to effectually control the sale and use of drugs of this kind.

As members of the drug trade, we cannot effectually hide behind the frequently made statement, that the distribution of drugs of this type to the consumer, is by peddlers or irresponsible dealers. While this may be true to a considerable extent, so far as the final distribution is concerned, it is safe to say that, at some one stage, all of the material sold in this country for use by *habitues* is obtained and obtainable from otherwise respectable and responsible members of the trade who are just not sufficiently alive, morally, to be strictly law abiding.

The recently enacted Harrison anti narcotic measure, should serve to furnish the information necessary to make existing statutes operative, and will, at all events, serve to place us, as members of the drug trade, on record as we have never been placed on record before, as to how far we are really in earnest in our efforts to restrict the sale and use of narcotic drugs.

I think I have said enough to show that existing laws, relating to the practice of pharmacy in its wider scope, are not being enforced as they should be, and that we as pharmacists owe it to ourselves, and to the communities that have entrusted us with certain responsibilities to eliminate many of the existing abuses.

We must, above all, realize that existing pharmacy laws place all who are registered in accordance with their provisions, on an equal footing, so that we, individually and collectively, must share any discredit to our occupation from the illegal practices of registered pharmacists. The people at large, rightfully look to the law for protection and if we, as beneficiaries under a law, allow others to impose on and to take advantage of persons who rightfully look to us for protection, we are in fact responsible, quite regardless of whether we ourselves are the transgressors or allow our competitors to continue their illegal practices unchallenged.

In conclusion I beg to make the one plea that we, individually and collectively, make an honest and an earnest effort to disabuse our own minds and also the minds of our fellow citizens, of the notion that all existing wrongs can be corrected by the enactment of suitable laws. Let us develop the necessary courage to call attention unflinchingly, to existing abuses and let us insist that, whenever possible, the laws now on our statute books be enforced; that such as cannot be enforced be repealed, and that, in all future-agitations for new legislation, the best interests of the people at large only be considered as the governing incentive.

---

## ENFORCEMENT OF DRUG LAWS.

---

BY FRANK R. ELDRED.

---

The effect of a law is altogether dependent upon its enforcement and the construction placed upon it. It is a matter of common observation that the objects of the law maker may be partially or entirely defeated by the method of administration. While there has been a very general discussion in regard to drug laws, the discussion of their enforcement has been confined largely to the officials to whom this work is entrusted. The enforcement of these laws, since the enactment of the Food and Drugs Act of 1906, has resulted in great benefit to the public; no class has profited more than honest drug manufacturers and dealers, and the entire drug trade has been placed upon a sounder foundation. As in every new undertaking, mistakes have been made and it has been necessary to learn by experience; the result has been a rapid improvement in the manner of enforcing the laws. The good accomplished has justified the methods which have been employed, but we have now advanced so far and conditions are so satisfactory, that it is time to enquire thoroughly into the possibilities of further improvement, for while it is important that drug laws should be standardized, it is no less important that the methods used in their enforcement should be standardized. In order to obtain a clear view of the situation, which is necessary before such improvements can be effected, it is necessary to approach the subject

from different angles. The present discussion is from the view-point of the manufacturer.

The first principle to be established, is that the laws were originally designed to protect the entire public, and not one class as opposed to another; only, as one necessary means for accomplishing this, did they provide for the punishment of law violators. In order to protect all classes, the drug dealers, wholesale and retail, and the drug manufacturers, must not be discriminated against and in assisting and instructing them in their efforts to serve the general public, officials can accomplish more than in any other way. The penalty should be reserved for intentional or persistent law violators. It is gratifying to note that this principle is being recognized in some of the states, and that the officials are publishing bulletins of information for the drug trade and for the consumer. Although the prime object of the law, was to protect the public, it has sometimes happened the prime object of the drug-official has been to punish the offender. Such officials have not yet learned the important lesson that most manufacturers and dealers are honest and intelligent, and are anxious to coöperate with them in protecting the public from impure or sub-standard drugs.

Another way in which the objects of certain laws have been perverted, is by arbitrary regulations or standards, which have been promulgated by officials charged with the enforcement of the law. These rulings are too often based upon a technical construction of the law, without due consideration of their effect upon the public.

It can thus be seen that, however excellent the laws may be, their power for good is dependent upon those who enforce them. It is, in some respects, unfortunate that laws relating to foods and drugs are, in most cases, administered by the same officials. When the Federal Food and Drugs Act, which is to a certain extent a model for the state laws, was passed, there were many men qualified as analysts of agricultural and food products, and this class of work had already received general recognition on account of the work of the agricultural experiment stations. Pharmaceutical chemists were few, and their work not generally known, therefore, with very few exceptions, the food chemist was called upon to administer the food and drug laws. The average food chemist, with drug work thus thrust upon him, found that, added to his inexperience in this line of work, the analysis of drugs was much more difficult than the analysis of food products. He was unfamiliar with the literature of pharmacy and disappointed, because drug analysis was not and could not well be treated, within the covers of a single volume, as in the case of food analysis. When chemists in charge of food and drug laboratories, endeavored to employ competent drug analysts, they found that this field of chemistry was practically unoccupied, and they were forced to employ as drug chemists, men without pharmaceutical training or experience. This condition resulted, at first, in the examination of certain drugs whose strength could be easily determined and, in order to make as great an impression as possible in the drug work, those which were known to deteriorate rapidly were usually selected. When this class of drugs was exhausted attention was then turned to those which required more skill upon the part of the analyst. Under the circumstances, this was probably the best procedure that

could be adopted, but it has led to some unfortunate results which will be pointed out later.

Bearing in mind this general discussion of the situation, let us examine in more detail, the procedure now followed in enforcing these laws. The first step to be considered is the collection of samples for examination. An important regulation under the Federal law, requiring three samples to be taken, one of which is available to the seller, has not been adopted by many of the States. The Federal law, also, requires a preliminary hearing for the alleged violator of the law, while some of the State laws do not provide for such a hearing. As the State laws differ among themselves, as well as from the Federal law, and as the methods adopted for the enforcement of the laws, differ even more than the laws themselves, no general statement can apply in all cases, and, in pointing out the abuses which exist, it must be recognized that these abuses are far from universal; in fact, most of the suggested reforms are already in effect in one locality or another. In those states where law does not provide for the collection of more than one sample of each product, the seller has no recourse in case of an error in analysis, indeed the samples taken are frequently too small to allow the chemist in the state laboratory to confirm his own results by a second analysis. It is usual in such cases for the state chemist to maintain his position; neither he, himself, or any one else can establish proof of the error, for there is no official sample left, and the statement of the seller, that any subsequent sample, which he may supply, is from the same stock as that obtained by the inspector, is usually discredited. In fact, the long delay in publishing or prosecuting such cases frequently makes it impossible for him to supply another sample from the same lot of goods.

The selection of products to be investigated, is of importance, and this has too often been decided by the ease of analysis and the probability of finding sub-standard goods, rather than by the importance of the product to the community. It was known that precipitated sulphur frequently contained calcium sulphate as an impurity, and although this product was of no practical importance, it became a favorite subject for examination. Drugs known to deteriorate rapidly, have also been much more frequently selected than drugs known to be stable. While it is conceded that these drugs should be pure and of full strength, time has often been devoted to them which should have been given to more important drugs. Because of this manner of selecting products for examination, statistics in regard to the percentage of adulterated drugs on the market, which have been compiled in the various states, give an entirely erroneous idea of the extent of drug adulteration. These statistics are also misleading on account of the use of the terms "illegal" and "adulterated," when only a slight variation from the legal standard exists, or even when an error has been made by the official chemist. The figures thus obtained are heralded by newspapers and other agencies, until a false idea of the entire drug trade is created in the public mind.

The collection of the sample, is followed by its examination in the laboratory, and it is here that the standard by which it is judged and the method of analysis, become matters of vital importance. Some of the standards are established by the Pharmacopœia, others are published in the form of regulations for the enforcement of the law, while still others exist only in the mind of the chemist

in charge of the work. If the standard is established by the Pharmacopœia, it has had the sanction of a committee chosen from recognized authorities on the subject, but the regulations are often framed by persons having no practical knowledge of the matter which they attempt to regulate. Manufacturers may have studied for years the preparation of a product which will best serve their trade, and such a regulation may force them to forego all the advantages derived from their study and to supply a product which is not what the trade demands, or to increase the price without a corresponding increase in value. There are instances where it has even been necessary to lower the quality, in order to comply with the regulation. The unwritten standards are usually arbitrary and represent purely personal opinions, some are supplementary to published standards and others are not based upon any such standard. They exist for the case in hand, and while they are not made the basis of legal action, it must be remembered that publicity may do more damage to a seller than a legal penalty.

The Pharmacopœia also establishes many methods of analysis, but where an official method is not available, some other method is arbitrarily selected, usually without a thorough investigation of its accuracy. The inconsistency has been observed of recognizing the need for coöperative work to determine the accuracy of a method, and, at the same time, using results obtained by it as a basis for prosecuting a manufacturer. Moreover, many recognized methods will give accurate results only when the chemist employing them has had long experience in their use and this is particularly true of the methods used in drug assaying. The difficulty of obtaining competent drug chemists has already been noted and it is therefore not uncommon to find erroneous results reported by state laboratories.

After the analysis has been made and the product is measured by the standard, it frequently happens that legal proceedings are not instituted, but the results are published in one way or another. Even though the manufacturer or dealer may have been entirely in the right, he has in this case no recourse, for any suit which he might bring to force a retraction, would only place him in the light of opposing the enforcement of the drug laws and he is usually handicapped also by having no official sample. The only hope of the seller, is that the official who has occasioned the undesirable notoriety will voluntarily correct his statements, even though this involves considerable embarrassment to himself. Publicity in such cases is deplorable, as also in cases of unintentional or technical violations of the law. It has been suggested, by certain malicious individuals, that agitation and publicity of this kind are necessary to justify the office and show the efficiency of the officer, but if any drug official ever shared this idea, experience quickly dispelled it, as the most successful officials are those who recognize the need for constructive work. It is difficult to see how publicity of this kind can be of service to the public, for it places the seller who may have committed no offense, or only an unintentional or technical one, in the same light as the dishonest or persistent violator of the law and thus affords no opportunity to guard against the latter class.

This discussion of drug law enforcement, is based upon specific cases which have come under the observation of the writer, and in order to illustrate what

has been said, a few of these cases will be presented, omitting, for obvious reasons, names and localities.

Several druggists received notice that the Tincture of Digitalis purchased from them was below standard. The manufacturer was also notified that his product was below standard but not where it had been obtained, this information, however, was given upon request. Further inquiry brought out the fact that the "standard" referred to was an extractive-standard which had been arrived at by making several tinctures by the U. S. P. process and taking the average of the total solids as a standard. It is needless to point out to any one familiar with the great variations in strength of digitalis that this unpublished standard was absurd and moreover, it had no legal standing in the state. The tinctures which were declared to be below standard, had been standardized physiologically and, as nearly as could be determined by such means, they were uniform in strength and represented ten per cent. of the strength of an active digitalis leaf. Upon calling the official's attention to these facts, he evaded the question as to the propriety of a physiological standard, and refused to modify his statement to the druggists. In the opinion of the writer, this and some of the other cases cited, would furnish just grounds for legal action against officials who thus attack the reputation of a manufacturer and whose only justification is that they do not hold the manufacturer legally responsible, since the original package was broken.

A somewhat similar experience, illustrates also the danger of erroneous analytical results. A number of druggists in a certain section of the country were notified that the Tincture of Belladonna, which had been taken from them, was found to be below standard. After an exchange of several letters, the manufacturer of the preparation learned the names and addresses of the druggists from whom the tincture had been obtained and also that the strength of the various samples was from 42% to 82% of the official requirement. Samples obtained from several of the druggists concerned, were found to be of full strength and upon assaying samples from all lots manufactured during the previous six years, the weakest was only seven per cent. below the U. S. P. standard. These results showed conclusively that errors had been made in the state laboratory, but they maintained the correctness of their assays and refused to send any portion of their samples to the manufacturer, or to give credence to the statements of some of the druggists, that samples supplied to the manufacturer were identical with those taken up by the inspector.

An almost identical experience with Tincture of Opium, could be cited, although it is well known that inexperience in assaying opium preparations is a frequent cause of low results. The same situation was met in a wiser way, by an official who has always recognized the value of conservative and constructive work. All the samples of Tincture of Opium collected, were below standard. Suspecting that this was due to an error on the part of the analyst, the director of the laboratory consulted an experienced drug analyst, and it was found that such was the case. The results were therefore not reported and no injustice was done.

Arbitrary methods of analysis are often stumbling blocks. Only recently it was insisted that 8.8% of water be declared upon a label, although by actual manufacturing data it was known that less than 5% was present.

The interpretation of results is a matter which requires the exercise of good judgment. When several pharmaceutical preparations were classed as "illegal" in a board of health report, it was pointed out to the chemist in charge, that the reported results varied from the official standards by less than the inherent error of the methods and that if a second determination had been made in each case (which had not been done) the result might have been as much above the standard as the first was below. The original statement, however, was never modified, for it was argued that, as the determinations which had been made were below the official requirements although ever so little, the clerks who compiled the statistics must class the products as illegal; thus the injustice to the manufacturers whose names had been published was not corrected. Fortunately, the forthcoming Pharmacopœia will provide against such errors of judgment, by establishing maximum and minimum limits, instead of giving exact figures as standards.

Many more such instances might be cited, as well as instances showing wise and judicious administration of the drug laws, but it is not desired to multiply examples and only one more will be given to show how premature publication of results affects the conscientious official. Two druggists were notified that their Tincture of Nux Vomica was below standard; the manufacturer being also notified at the same time. Samples were obtained from the druggists, assayed by the manufacturer and found to be of standard strength. This fact was communicated to the drug official with a request for portions of his samples, the request was granted and they were found to be of standard strength, the mistake was acknowledged and rectified by letters to the druggists.

These criticisms and examples have been given only for the purpose of justifying the suggestions which are to be offered. The basis of any plan for the enforcement of the drug laws should be coöperation between drug officials and all branches of the drug trade. In the first place, products should be selected for examination on account of their power for good or evil to the community. Three samples should be taken and sealed in the presence of the inspector and dealer, one should be kept by the dealer, one used for examination and the third filed for use in case of a disagreement. If the law does not provide for duplicate or triplicate samples, then the druggist or manufacturer should insist on keeping a sample which has been sealed by the inspector, and this should be retained until a report is received from the official in charge of the work. Should the druggist or manufacturer fail to take this precaution he should be requested to do so by the inspector. In case the product is reported below standard, this sample can then be examined by the manufacturer or by a commercial chemist and, if their findings do not agree with those of the official chemist, the triplicate sample, which should be in reserve, can be used in settling the controversy. In any event, after the sample has been examined by the official chemist, his findings, if adverse, should be reported first to the manufacturer of the product. If he can show that the product is of standard quality, of course the report should go no further. Should it appear that only a technical or unintentional violation exists, not due to ignorance or carelessness, it is difficult to see how any good can be accomplished by making the matter public. Of course, honest differences of opinion will arise, but if the manufacturer cannot prove that he is in the right, the drug official can then have recourse to publicity or legal proceedings. After

the matter has been discussed with the manufacturer, the dealer should receive notice of the disposition of the case, and, in fairness to both dealer and manufacturer, notices should also be sent when the drugs examined are found to be of standard strength. This course would unite the honest manufacturers and dealers with the drug officials in their campaign against impure and adulterated drugs and would thus result in a more adequate protection of the public against them.

Much constructive work can be done by the drug officials, with expert assistance which they can easily enlist, in working out proper standards and in establishing accurate methods of analysis. It is needless to say, that both standards and methods should be published, and that intelligent criticism should be encouraged. Bulletins of information for the drug trade and the public, can also be made very valuable and a good start has already been made in this direction by some of the states.

If some such plan of action could receive the support of this and other organizations interested in the enforcement of the drug laws, it would be only a short time until all antagonism between officials and dealers would disappear and everybody concerned would be working harmoniously for the enforcement of these laws.

## A PLEA FOR A HIGHER STANDARD FOR ENTRANCE TO THE PROFESSION OF PHARMACY.

---

C. B. JORDAN, PH. C., M. S.

---

We are living in an age of progress in which the arts, sciences, and trades are making rapid advancement. Old methods and standards are inadequate to cope with modern problems. The professions allied to pharmacy, medicine and dentistry, have changed their methods and raised their standards and are giving to the public better service than ever before. It behooves us, the pharmacists of the country, to advance with and keep abreast of this progress or we will lose out and the profession will be seriously injured.

If pharmacy is a profession, the standard for entrance to it should be comparable to the present-day standards for entrance to the other professions. But is pharmacy a profession? I am ashamed to say that this question is asked in all seriousness by the pharmacists themselves. A short time ago, a series of articles appeared in Merck's Report in which this question was viewed from all standpoints by the pharmacists of the United States and some men who are prominent in pharmacy to-day declared that it is not a profession but a commercial business. Careful consideration of these articles, showed clearly that pharmacy will be what we pharmacists desire to make it. If we wish, we can make it a commercial proposition, or we can make it a dignified profession.

What are some of the things that should be done to make it a dignified profession? First, and most important, we must raise the standard for entrance to the profession.

Our standard to-day is very low. To prove this, I have only to cite the fact, that some of our state legislatures have seriously considered such bills as the one to register, without examination, all persons who have been connected with a drug store for ten years, be it in the capacity of porter, errand-boy, or soda-fountain tender.

We were all highly indignant when a New York judge declared that pharmacists are a class of men with little learning. This, however, shows us how people outside of the profession view us. When we stop to consider that in many of our states, a man can become a full-registered pharmacist by serving a four-year apprenticeship, which may mean selling patent medicine and kodaks for four years, and passing an examination so easy that he can prepare for it by taking a three months' "quiz-compend-erum" course in one of our so-called schools of pharmacy, we must concede that they are, in a measure, justified in taking such a view of us. Men in the other professions, the lawyer, engineer, doctor, dentist, chemist, and even the agriculturist, look upon our profession as an inferior one, because it requires so little preparation to enter it.

Ten years ago, the profession of medicine was in a rut. Little or no standard was maintained in many states, and we suffered from an over-production of incompetent and poorly-trained physicians and the public had little confidence in the profession. By the combined efforts of the physicians and their boards of medical registration, all this has been changed. Standards have been raised and maintained, so that to-day, in many states, a person must complete a six year college course and pass a rigid examination, before he is allowed to practice and, in a short time, he will be compelled, in addition, to spend one year in hospital work. This elevation of standard has accomplished wonders for the profession and to-day we have fewer but better physicians and the public is better served. Pharmacy is to-day, where medicine was ten years ago and an elevation in our standard will do for pharmacy what it has done for medicine.

The standards for entrance to the trades, have been raised with a like result. To illustrate, a plumber must serve four years apprenticeship, and does not receive full wage until the end of six years. The pharmacist serves a four-year apprenticeship which may mean four years behind a soda fountain and then takes an examination that he can prepare for by taking a three months' "erum-course." Plumbing is a trade, while pharmacy is a profession, and the only difference in preparation, is that the pharmacist must take this easy examination. I am speaking now of the standards obtaining in many of our western and middle-western states. I know that some states have higher requirements, and, as a result, the pharmacists in these states enjoy a much better professional business.

As a result of our low standard, we have a great army of poorly-trained men, causing fierce competition, low wages, long hours, the commercialization of the profession, and lack of public confidence. There is hardly a city, village or hamlet in the United States, that does not contain two or three times as many

drug stores as are necessary, to carry on the legitimate drug business of the community. This fierce competition causes the druggist to add side-line after side-line, until it is difficult, in some cases, to distinguish the drug store from the notion shop. It also causes the druggist to pay his clerks low wages and to work himself and his clerks long hours, in order to make a living.

Fierce competition demands cheap help, cheap help demands low standards, low standards cause overcrowding of the profession, and overcrowding causes fierce competition. Thus we have a complete cycle of cause and effect. If we attempt to break the chain at any point, we are told that we will disturb trade conditions. What if we do disturb trade conditions? You cannot remove a cancer without causing the patient pain. An uplifting of standards will not debar any one who is already registered, and the effect upon trade conditions will be so gradual that any one who is failing, will have time to adjust his affairs and enter another field.

Our low standards permit many undesirables to enter the profession, men who have no respect or regard for it, but who adopt it for the purpose of private gain. The "booze and dope" seller can easily qualify, and conduct a "saloon or dope joint" under the guise of a drug business and thus bring the legitimate pharmacist into disrepute. Only a short time ago, a saloon-keeper applied for membership in one of our state pharmaceutical associations, believing that, since he was pretending to conduct a drug business, he was eligible for membership.

The profession of pharmacy is not very attractive to our best prepared young men, because of the small compensation received by the drug-clerk. The shoe-clerk and the grocer-clerk receive as much compensation and have much shorter hours, with no educational qualifications for entrance. A young man who has completed a high-school course, and who is trying to decide what profession to enter, usually steers clear of pharmacy. A great many men who are in the profession, are dissatisfied with it and do not encourage their friends who are well-prepared to enter it. I have heard men who are pharmacists, declare that they would never let their sons enter the profession. Under these conditions, we cannot hope to recruit the profession from the ranks of the best-prepared young men.

There is a demand to-day, more than ever before, for well-trained pharmacists. The younger physicians are asking for careful urinary analysis, the incubation, isolation and determination of bacteria, the determination of the bacterial content of the secretions of the body, etc., all of which require skilful laboratory workers. I am sorry to see that, in some places, this work, instead of going to the pharmacist where it belongs, is going to the younger physicians because they are better prepared for it.

Our medical colleges are laying much stress upon bacterial diagnosis and upon the use of biological products, in the treatment of diseases. The pharmacist should be prepared to assist the physician in this work. To be prepared for this, a person should have a good college course of four years or more. What incentive is there for a young man to secure this preparation and become registered as a pharmacist when he is placed on a par, in the eyes of the law, with the man

who has sold patent medicines and kodaks for four years and has taken a short "cram-course" in pharmacy?

I have shown that our low standard causes overcrowding of the profession, fierce competition, low wages, poorly-trained and incompetent pharmacists, and lack of public confidence. Therefore I believe that the hope of the profession lies in an elevation of standard for entrance to it.

I would respectfully urge that the Association inaugurates a campaign to secure a higher standard for entrance to our profession.

---

#### SIMPLE METHOD FOR DETERMINING GLUCOSE IN DIABETIC URINE AND OTHER LIQUIDS.

Ten mls of the urine is measured into a 200-ml flask, and water added to make 200 mls. A solution of potassium carbonate (2 oz. to 6 oz. of distilled water) is filtered and made up to 8 fl. oz. To 20 mls of the diluted urine, 10 mls of the potassium carbonate solution is added in a small flask, the mixture boiled carefully for three minutes, cooled, and made up to 50 or 100 mls with distilled water. A solution of pure glucose is prepared, 1 Gm. in 200 mls of distilled water; 20 mls of this and 10 mls of the potassium carbonate solution are boiled together in a small flask for three minutes, cooled, and made up to 50 or 100 mls. The two solutions are then compared by holding the glass tubes over a piece of white paper at an angle of 45°. By pouring the liquid from the known solution into a measure glass until the tints of both are alike, and observing the amount of the known glucose solution used, the percentage can readily be determined; for example, if 27 mls of the pure glucose solution were required for the solution, then, multiplying by 2 we obtain 5.4 as the percentage of glucose in the urine.—A. F. Dimmock, M. D. (Brit. Med. Journ., August 29, 1914, 399).

#### THE MOST POWERFUL MAGNET.

Probably the strongest electro-magnet is produced on the new method which Professors Perot and Deslandres are applying with success. Their idea is to take one of the strong electro-magnets of laboratory type with pointed pole-pieces which already give a high value of the magnetic field, and then to put an extra coil around the air-gap between the poles so as to add considerable to the field. Such coil is made of thin copper strip and is cooled down as low as -30 degrees C. by a current of oil, so that a remarkably heavy current can be put into the coil without burning it; for instance, it will stand a current density of 1800 amperes per square millimetre, using a 0.2 millimetre strip. Such a coil is put on a Weiss electro magnet which carries the usual coils, and gives 41,000 gauss for the magnetic field strength. Putting on the 30,000 ampere-turns of the new coil, this brought the field strength up to 51,000 gauss, and it was only lack of current supply that prevented running as high as probably 60,000 gauss, so that a most powerful field can be thus obtained.—*Boston Transcript*.

## Editorial

ERNEST C. MARSHALL, Acting Editor.....63 Clinton Building, Columbus, Ohio

### PATIENCE AND "PEARSON'S."

THERE is no human quality so useful as Patience under misrepresentation; a tolerance which endures; a serenity of mind which allows oneself to be maligned; which, confident of strength sees petty natures lie and injure without a word of protest or one thought of dismay. Sanco Panza tells us, "Patience and shuffle the cards." And we should have been patient under the criticism of the profession which recently appeared in a fourth-rate magazine, rather than to have encouraged and stimulated their untrue attack by striving to show them that they were wrong. They knew they were wrong, that they were misrepresenting matters, but they simply wished to bring a dying venture into the lime-light, to acquire notoriety. Did they care that what they said was untrue? Not at all. Did they care what injury they might do by their false misrepresentation? Did they care that they maligned a body of men whose services to humanity and to every community are second to none? They cared not for this. And the only answer to such criticism is a dignified silence. You please a blackguard, when you notice him. To reply to him is as unwise as for a gentleman to answer the gibes and jeers of a boozy corner-bully.

"It don't pay to do much talkin'  
When you're mad enough to choke,  
For the word that stings the deepest  
Is the word that's never spoke.

"Let the other feller do the talkin'  
Till the clouds are cleared away,  
Then he'll do a heap er thinkin'  
'Bont the things you didn't say."

### DRUG IMPORTATIONS.

IN view of the testimony recently given by Mr. Harry B. French, President of the Smith, Kline and French Company of Philadelphia, before the Committee on Uniform Food and Drug Regulations of the Chamber of Commerce of the United States, it is evident that it is exceedingly difficult for Government officials at different ports, however honest their intention, to pass judgment upon drug-importations and arrive at the same conclusions.

Mr. French testified that:—

"If the Government makes a statement that the goods will not be released because of certain allegations on the part of the Government, these allegations are made to the importer and he is given an opportunity to appear before the collector of the port of entry and present arguments. The samples and arguments are then sent to Washington, and if the Washington officials uphold the local officials, the importer has no alternative but to re-export the goods. The tendency at Washington is invariably to support the reports received from the authorities of the different ports, and the reports vary with the numbers of ports.

"For example: (1) We imported Asafetida. Its solubility test was 40 per cent. It was rejected at Philadelphia. The goods were re-exported to London. We then bought Asafetida in New York. It tested only 30 per cent. solubility and we so labelled it. The goods were seized by the U. S. officials, but the Courts decided that the goods were legally our property because they were properly marked: (2) We imported Myrrh through New York. The Collector of the Port refused to pass the drug on the grounds that it contained too much ash

and did not answer the U. S. P. description. The Pharmacopœia gives no standard for ash. The Government officials suspected the presence of foreign gum. They did not assert that they could show its presence, but they refused the admission on suspicion, and their stand was upheld by the Washington authorities. An independent examination by one of the leading experts of the country showed the entire absence of foreign gum; (3) We imported Saffron through Philadelphia. It was refused admittance on the ground that it contained too much moisture, ash and sugar. Saffron is not official in the present U. S. P. (VIII) but the next edition of the U. S. P. (IX) will permit 7.5 per cent. of ash. The content of ash in the Saffron was less than that allowed by the new Pharmacopœia. There is, of course, no moisture-standard in the U. S. P. (VIII), but the next edition of the U. S. P. (IX) will permit 14 per cent. The Saffron rejected contained a slightly larger percentage of moisture than the standard to be, but this could have been readily removed by drying before admission (as it was later). As regards the sugar, it can be said that all Saffron contains sugar, and the quantity present was less than the standard. Other instances of abuses in drug importations can be cited."

According to Mr. French, the following abuses are possible:—

"The same quality of drug may be brought to five different ports. At one port the drug may be permitted entry without examination; at another port the drug may be examined and admission granted; at the third port the drug may be examined and refused admission on grounds which have a legal basis; at the fourth port importation may be refused because of suspicions on the part of executive officials and for reasons that are not legal, and at the fifth port the drug may be examined and delivery made on conditions that the goods are marked in a certain manner."

Drugs imported into the United States must comply with the provisions of the Drugs and Medicine Act of 1848 and the provisions of the Food and Drugs Act of June 30, 1906. These two acts are held by the Attorney General to be cumulative. Decisions whether drugs shall be admitted in the United States rest with the administrative officers of the Government. Neither act provides for a review by the courts of such decisions. Under Section 11 of the Food and Drug Act, importers are privileged to appeal to the Secretary of Agriculture and submit testimony, but such appeals are usually made or referred to the Bureau of Chemistry (which may have prejudged the case), and are then passed upon by the Secretary of Agriculture, whose decision is final.

In a letter to Hon. F. M. Simmons, Chairman of the Finance Committee of the U. S. Senate, Secretary Houston, of the U. S. Department of Agriculture, writes:

"It is true, as stated by Smith, Kline & French Co., that there have been differences in the findings of the Department's chemists at different ports of entry with respect to crude drugs. The number of samples of imported food and drugs examined since the Food and Drugs Act became effective, January 1, 1907, has been enormous. It has been impossible to avoid differences in results of analyses made by different chemists at the same or different ports. The Department, however, has endeavored to be fair and consistent in its rulings. When differences in analyses have been noted, or the results of the analyses have been questioned by importers, such analyses have been made before arriving at decisions. It is believed that as a result of the experience of the Department, fewer differences in analyses occur now than formerly, but in view of the large number of samples of imported food and drugs required to be examined, it is to be anticipated that there will be some differences in the findings of the chemists in the future."

And it is these differences that should be corrected. The methods of examining imported drugs at the ports of entry should be standardized, as suggested by the Drug Trade Section of the New York Board of Trade and Transportation,

and the conditions of entry made as uniform as possible at all ports. The "personal equation" factor should be eliminated. Rejections should be based on demonstrable facts and not on suspicions.

It must be borne in mind that customs officials exercise the power of passing importations without examination; that it is within their power to give legal reasons for the rejection of an importation, which objections, however, may not have been founded on fact, and yet the importer has no legal redress. It is manifest that such a system gives a large scope for the use of personal influence, and offers the possibility of gratifying private grudges. It is not asserted or intimated that any of the officials of the ports of this country are guilty of such nefarious practice, but it is certain that the system encourages such practice. Russia is the only great civilized country in the world that has a bureaucratic government and the power of Russian officials to send citizens to Siberia, without trial, should not commend the system to American citizens.

Importers of drugs should be given the right of judicial appeal when a refusal of delivery of goods is made by the Treasury Department, a right accorded by law to importers in the assessment of goods for duty under the Tariff Act.

It may be argued that it would not be expedient to give importers the right of appeal to the courts upon matters of a scientific or technical character—that such questions should be determined only by Government officials trained in the work. But Government officials are human and naturally sustain the findings of each other. Whoever heard of a Government official in any department failing to sustain the scientific or technical report of a fellow official?

As to the lack of scientific or technical training by the Court, the latter could readily appoint a scientific or technical referee (as it does other referees) who could take testimony and report upon the facts to the Court, when an impartial decision could be rendered.

Section 11 of the Food and Drugs Act should be amended to provide for appeals to the courts from decisions of the Secretary of Agriculture in the matter of *both* food and drug importations, and it should be entirely possible to do this, and also, "adequately safe-guard the admission into the United States of only such foods and drugs as are not adulterated or misbranded or otherwise in violation of the Act."

The great principle involved in the demand for an amendment of the Act is that American citizens should not be deprived of their constitutional rights and their business placed at the mercy of executive officials without the power of judicial appeal.

J. W. ENGLAND.

## THE HARRISON BILL.

THIS law has been discussed at such length that it is almost unnecessary to speak of it except to note the fact that *Jacta alca est*, it is now the law of the land, and as such it must be obeyed.

It is certainly very satisfactory that many vexatious and burdensome restrictions have been eliminated from the original bill and, in its present form, it is as unobjectionable as such a bill could well be to the trade. The National Drug Trade Conference has again demonstrated the wisdom of its establishment, for by its wise direction the bill has been wisely amended and much that was mischievous has been eliminated.

The country demanded some law to control what was termed the drug-evil. Exaggerated statements and garbled statistics had engendered the belief that the nation was largely composed of weak-minded people, who must be protected against themselves. Now that this law is passed it may be that those who thought the nation was going straight to "the demnition how-wows" will be for a time satisfied, will allow it to demonstrate its usefulness, and will cease their striving to impose further restrictions upon an already overburdened profession.

The results of the bill may be salutary. It must be said that the intent of the framer of the bill and of its protagonists is most commendable, but sometimes laws intended to be restrictive fail, because they attempt to do too much.

Lord Chesterfield, in his famous letters to his son, told him that he wished him to frequent the Courts of Europe, principally to see "with what little wit the world was governed." And if this law proves ineffective, it will not disappoint those of us who have seen so many other laws fail in attaining the results which they were intended to accomplish.

## SAN FRANCISCO.

THE attention of the members is called to the advertisement of the World's Fair Company, which appears on Page VII of our advertising pages.

This company has the backing of some of the leading citizens of Columbus, and the inclusive price, which they make for the trip, embraces unusual features for the excursion to the meeting.

The special trains which this company will run will be equipped with moving-picture outfits and it is planned that cabaret artists will accompany every party to relieve the tedium of the long railroad journey.

Full information regarding these many attractive features may be received by writing to Mr. Robert C. Byers, the District Director, at 27-28 Ruggery Building, Columbus, Ohio, and the name of every person so writing will be placed upon a list to receive the latest information in regard to the Fair and the advantages of use of the company's arrangements in going and returning from the meeting.

## JAMES HARTLEY BEAL, PHAR. D., SC. D., LL. B.

Professor Beal was born on the twenty-third of September, 1861 near New Philadelphia, Ohio. He received the education of that municipality and during the school-vacations he worked at farming and coal-mining. After leaving school he entered the profession of Pharmacy in Urichsville, Ohio, and afterwards was employed in its active practice in Akron, Ohio.

Filled with the ambition for a college-education he entered Scio College graduating from that institution in 1884, with the degree of Ph. B. He then studied Chemistry and Pharmacy in the University of Michigan, also attending the Law School of that institution. Later he entered the Cincinnati Law School, from which he graduated in 1886. He has never practiced the profession of law, but his studies in that line have been decidedly useful to the profession in the service he has rendered to it in the preparation of many legislative bills and the study of Pharmacy Laws.

In 1895 he received the degree of Doctor of Science *in Curia* from Mount Union College and Phar. D. from the University of Western Pennsylvania. He was Dean of the Department of Pharmacy of Scio College from 1887 until 1908, and was the acting president of that institution from 1902-1904.

His activities in the Association has embraced all fields of its endeavor. He became a member of the Association in 1892. In 1897 he was elected Chairman of the Section on Education and Legislation. He was chosen First Vice President in 1900, and President for the year 1904-5. He was President of the Conference of Pharmaceutical Faculties in 1906-7; President of the Ohio State Pharmaceutical Association in 1898-9; Chairman of the Committee on Uniformity of Legislation, Methods of Analysis and Marking of Food Products at the National Pure Food and Drug Congress in 1898. At the present time he is Chairman of the Board of Trustees of the U. S. P. Convention and a member of the Food and Drug Trades Conference and a member of the Board of Directors of the American Druggist's Fire Insurance Company of Cincinnati, Ohio.

In 1911 he was elected General Secretary of the Association and Editor of the JOURNAL, from which positions he resigned in June of last year. He has contributed largely to pharmaceutical literature and is the author of many books relating to Pharmacy and its co-ordinate professions, among these works being "The Elements of Pharmacy," "Chemical Arithmetic," "The Era Course in Pharmacy," "Pharmaceutical Interrogations," "Interrogations in Dental Metallurgy," "Equation Writing."

Prof. Beal was a member of the Seventy-fifth General Assembly of Ohio. In his legislative service he was Chairman and member of important committees, and he left upon the statute-books of the state an enduring impress in the Beal Local Option Law, now one of the most effective and wise laws of the State.

For many years Dr. Beal has been interested in the oil and natural gas properties of the Midland region.

In 1886 he espoused Fannie Snyder Young of Urichsville and two children have been born of that union; George Denton Beal, Associate Professor of Chemistry of the University of Illinois, and Nannie Esther Beal. Prof. Beal now resides in Urbana, Ill.

## Scientific Section

Papers Presented at the Sixty-Second Annual Convention

### THIRD ALKALOID FROM GELSEMIUM.

A. E. STEVENSON AND L. E. SAYRE.

The Proceedings of the American Pharmaceutical Association for a number of years past have recorded the progressive work of the laboratory of the University of Kansas in regard to the alkaloids of Gelsemium.

Last year a report was made on the further study of Gelsemium, giving, in the first place, the percentage of various alkaloidal and acid products from fifty pounds of the crude drug; secondly, a very complete statement as to the physiological action of the alkaloids, Gelsemine and Gelseminine. This latter work was contributed by Doctor F. P. Chillingsworth. It may be said in passing that during the past year, Doctor S. A. Mathews, pharmacologist, has gone over the physiological action of Gelseminine and his results confirm those of Doctor Chillingsworth.

During the past year, two separate lots of Gelsemium, from different sources, have been investigated for alkaloidal constituents. The results of this work, being somewhat noteworthy, we desire to record them in the present Proceedings of this Association.

The first lot of Gelsemium consisted of one pound of the concentrated fluid extract, which assayed .4% of total alkaloids. The second lot consisted of five pounds of powdered gelsemium root, ground especially for investigation.

By a change of a method of procedure, suggested by one of us (Stevenson) we have secured, as a result, a purification of what seems to promise a third alkaloid, which furnishes definite forms of crystals in the alkaloidal condition as well as in two of its salts, namely, the hydrochloride and the nitrate, the only ones thus far studied.

The method of procedure for the isolation of this alkaloid was practically the same in the two cases and, as results were the same, we shall give only the details for the isolation from the powdered drug, which was as follows:—

Five pounds of the finely-powdered drug were first treated with 70% alcohol until exhausted. The tincture thus obtained was evaporated to a viscous liquid. This concentrated liquid was then extracted with five litres of chloroform, divided into five one litre portions. The chloroformic washings were then mixed and the chloroform distilled off until the liquid was concentrated to 100 cc. This second concentrate was then treated with .5% hydrochloric acid, washing the concentrate in a separatory funnel with five portions of 100 cc. each of the above acid; then six times with 100 cc. each of .25% hydrochloric acid. The combined acid solutions now were shaken out with 900 cc. of benzol in three portions of 300 cc. each. This was to remove the gelsemic acid. Then the residue was shaken out with

chloroform, 400 cc., 300 cc., 300 cc., and 300 cc.—in all, 1300 cc. in order to remove any trace of gelsemic acid.

The chloroformic solution was distilled until a highly concentrated chloroformic solution was left behind. This concentrate was washed with water. This aqueous solution, which was found to be strongly alkaloidal, was evaporated to a solid. This was completely soluble in alcohol. The alcoholic solution was evaporated until highly concentrated and then mixed with sand and dried in current of warm air. The powder which resulted was extracted first with acetone; the residue, left behind from the acetone treatment, was then extracted with alcohol. On evaporation of the alcohol, the hydrochloride of the alkaloid in question crystallized out. Photographs of the crystals of the alkaloid, the nitrate and hydrochloride, are herewith appended.

"SEMPERVIRENE" SALTS AND ALKALOID.

HYDROCHLORIDE.  
(Crystals on left are the more characteristic.)

NITRATE.

FREE ALKALOID.

We would suggest as a name for this alkaloid, "Sempervirene." This alkaloid exists in gelsemium only in minute quantities (the exact amount obtained was not determined), and it was only through the insolubility of its salts that it was discovered. On adding hydrochloric acid, sulphuric acid, or nitric acid to a neutral aqueous solution of the hydrochloride, the hydrochloride, sulphate and nitrate, respectively, of the alkaloid are precipitated. Phosphoric acid does not cause a precipitate. The alkaloid is so completely precipitated by the addition of nitric acid to the aqueous solution of the hydrochloride, that only a faint opalescence is produced by the addition of Mayer's reagent to the filtrate. In the insolubility of its nitrate the alkaloid shows a striking similarity to cinchonamine.

The nitrate is slightly soluble in alcohol from which it may readily be crystallized, separating in the form of well-defined yellow needles. The nitrate begins to darken when heated to  $210^{\circ}$ ; at  $280^{\circ}$  C., it formed a black, partially fused mass.

The free alkaloid was prepared from the re-crystallized nitrate. Its chloroformic solution was yellow. The alkaloid formed pale yellow crystals, the characteristic form from alcoholic solution seeming to be short and rather thick needles.

The hydrochloride formed pale yellow crystals easily soluble in alcohol, which

crystallized on evaporation of the aqueous solution in the form shown in the photograph above.

We are convinced that this principle differs from any one that has heretofore been reported and, since we have obtained the same alkaloid from both the fluid extract and from the drug, we cannot believe that it is due to any foreign admixture in the drug. But, in order to assure ourselves that this is not the case, we are having ground, at the present time, a specially selected gelsemium for the purpose and will go over the same work repeatedly in order to reassure ourselves that no error could have crept in from such a source.

Referring to a letter from J. U. Lloyd, with whom one of us (Sayre) has had some correspondence in connection with this subject, he says: "I take it you have surely taken the pains to see that your new alkaloid is not a chemical product, in which some reaction on another of the alkaloids has produced the new one as a split off?" He further states,—“Please bear in mind the fact that drugs at different seasons of the year contain different constituents or varying amounts of the usual constituents, and that possibly you will find variations in gelsemium, in more directions than one.”

It would be of interest to us to continue this investigation to see whether there are gelsemiums of different collections in which this alkaloid is absent.

---

## THE STRUCTURAL VARIATION OF ALLSPICE.

---

WILLIAM MANSFIELD, M. D.

---

Allspice, *Pimenta officinalis*, is a New World spice. It was not known in Europe until after the discovery of America. The exact history of its discovery, and its subsequent introduction into commerce, is obscured in the haze of passing years. It is definitely known, though, that in the seventeenth century it was imported into England, where it was known by a variety of names. About the close of the seventeenth century, it was in wide use in England as a condiment, and was sold as Jamaica Pepper or allspice. The latter name is in common use to-day, but we do not hyphenate the word as they did formerly. At the beginning of the eighteenth century, allspice was used in medicine. It was not until 1721, however, that allspice was made official in the British Pharmacopœia; and not until 1816, was it made official in the United States Pharmacopœia. In the 1816, U. S. P., allspice was recognized under the name of Pimento; the common name was given as Jamaica Pepper, and its botanical origin as *Myrtus Pimento*. In the 1820 and 1828, Pharmacopœia the oil was official under the title of *Oleum Pimenta*. In the 1830, U. S. P., its title was Oil of Pimento, from Pimento. In the 1831, U. S. P., both the fruit and the oil were official. The title of the fruit was *Pimenta* *Myrtus pimenta*, the berries. The title of the oil was *Oleum Pimenta*. In the 1842, U. S. P., the title of the fruit was *Pimenta*, Pimento. The unripe berries of *Myrtus Pimenta*. The title of the oil was *Oleum Pimenta*, Oil of Pimento, from Pimento. In the 1857, U. S. P., the title of the fruit was *Pimenta*, Pimento, the unripe berries of *Myrtus Pimenta*. The title of the oil

was *Oleum Pimentæ*, Oil of Pimento, from Pimento. In the 1868, U. S. P., the title of the fruit was *Pimenta*, Pimento,—“the unripe berries of *Eugenia Pimenta* (*De Candolle*).” The title of the oil was *Oleum Pimentæ*, oil of Pimento. It was not until 1873 that the name Allspice was applied to this drug. In the 1873, U. S. P., the title of the fruit was *Pimenta*, Pimento, *Syn.* Allspice,—“the unripe berries of *Eugenia Pimenta* (*De Candolle*).” The title of the oil was *Oleum Pimentæ*, Oil of Pimento. In the 1880, U. S. P., the title of the fruit was *Pimenta*, Pimento, *Syn.* Allspice. “The nearly ripe fruit of *Eugenia Pimenta* (*De Candolle*).” (*Nat. Ord., Myrtacæ*).” The oil was official as *Oleum Pimentæ*, Oil of Pimenta, Oil of Allspice. “A volatile oil distilled from Pimenta. Prep. *Spiritus Myrciæ*.” This oil was described, the specific gravity given, etc. The 1883, U. S. P., was similar to that of the Pharmacopœia of 1880. In the 1890, Pharmacopœia, its title was *Pimenta*, and its common name Pimenta. Its botanical origin was given as *Pimenta officinalis*, (*Lindley*). (*Nat. Ord. Myrtacæ*). The oil was of-

Allspice with Male Flowers

Allspice with Perfect Flowers

ficial as *Oleum Pimentæ*, Oil of Pimenta, and it was directed that the oil yield 65 per cent. by volume of Eugenol, and a method was given for its assay.

Its first use as a condiment, is the predominating use of allspice to-day.

Allspice is a native of the West Indies. It is also found growing in Central America, Mexico, Costa Rica, Venezuela, and in Cuba. In the latter place, Dr. Britton, the well-known author of the Flora of Northern United States and Canada, has frequently observed it while exploring the wilds of the island. It is cultivated to a limited extent in most tropical countries. The climate and soil-conditions of Porto Rico are well-suited to the growth, and there is little reason why it should not be grown on a commercial scale on the island.

Most of the allspice in the market is collected on the Island of Jamaica. The allspice tree, which is common to all parts of the island, is usually propagated by birds, which are very fond of the ripe fruit. In their flight about the island, the seeds are dropped on the ground. So many seeds are distributed in this manner, that it is not necessary to cultivate the seed and transplant the young trees. In fact, until recent years, the people believed that only bird-distributed

seed would grow. This belief has been disproved by experiments which have shown that if the pulp is removed from the seeds, they will renew their growth and develop into fruit-bearing trees within a period of five years.

The allspice plantations of Jamaica are made up of wild trees, standing twenty to thirty feet apart. The land between them is kept clean of trees and shrubs.

The allspice tree grows to a height of twenty to thirty feet. The bark of the tree is smooth, shiny, and of a greenish-gray color. The leaves, which are arranged opposite on the stem, vary in length from two to seven inches. They are dark-green, shining above, lighter and pellucid-punctate on the under surface. When held between the eye and the source of light, the leaf appears full of small, rounded, translucent bodies. These are the oil-cavities, in which the oil is stored. When the leaf is crushed, the oil-cavities are broken, and the characteristic odor of the oil of allspice is obtained. The oil does not evaporate readily from the dried leaf. Herbarium specimens, collected years ago, still smell aromatic when crushed. It is indeed, surprising to me that the oil is not extracted from the leaves on a commercial scale.

The flowers are of two kinds, and are borne on different trees. The fleshy, perfect flowers, which are the most abundant, grow in clusters. The calyx-tube is ovoid, and divided above into four small, rounded, spreading, persistent sepals. The four white petals are rounded, and in the mature flower are bent back. After fertilization, the petals fall from the developing fruit. The stamens, which are indefinite in number, stand erect from the throat of the calyx. The pistil has a short, erect style, and a two- or three-celled ovary.

The other type of flowers common to allspice, is the so-called "male flowers," (staminate flowers), which are similar in structure to the above, with the exception that the stamens are more numerous, the pistil is abortive, and the ovules are not fertile. It is claimed by many planters, that larger yields of fruit are produced, if a few of the trees bearing staminate flowers are allowed to grow among the trees bearing perfect flowers. This is quite believable, for the reason that this would bring about cross-fertilization, which many plants secure by reason of their floral structure, or by having fertile flowers of one kind only growing on a plant, just as we have in staminate flowers of allspice.

The fruit, which begins to develop as soon as fertilized, matures in August. When fully developed, the fruit is a fleshy berry, about the size of a pea. The outer part of the fruit, is fleshy and of sweet, aromatic taste. When such a fruit is dried, it retains little of the aromatic properties of the slight, immature fruit. The full grown, but immature fruits, are gathered for market. The gathering is usually done by children, who snap off the fruiting branches by the aid of a forked stick. Later, the branches with fruits, are collected in piles under the tree, and the fruits separated from the stalks and leaves. The green fruits are then taken to paved courts, where the berries are spread out on the pavements, or on specially constructed frames. The berries are frequently turned during the day by a workman who uses a wooden rake for the purpose. At night, they are covered, in order to protect them from rain and dew. Under favorable conditions, allspice is dried at the end of seven to ten days. The variation in time required for drying allspice, is due to possible rainy days.

Allspice is sometimes dried by placing the berries on drying-frames over heat. When thoroughly dried, they are placed in bags and sent to market.

Allspice of commerce is a fruit, varying in color from brownish-gray to grayish-brown, to reddish-brown, to reddish-black. All the fruits, with the exception of the reddish-black ones, which are at first sweet, then sweet-aromatic, and finally slightly astringent, are first aromatic and then aromatic-astringent. The surface is granular in appearance and rough to the touch. The outline of the fruit varies from indistinctly four- to indistinctly three-sided. The upper part of the fruit is crowned either with the four-parted calyx or its fragments, or by the remains of the cohering calyx-tube, which appears as a gray ring around the rim of the tube. In the center of the small depression, there is a persistent style of variable length. The base of the fruit is either marked by a slightly depressed scar, or attached (rarely) to a short stalk.

On cross-sections the pericarp is about 1 m.m. in thickness. The septa is thin and membranous. The fruit is two to three-celled, and from one to three-seeded. In the one-seeded form, fragments of the septa are visible. In each cell there is a solitary seed. In the two-celled fruits, the seed is slightly reniform, two-sided, concave on the inner face, and indistinctly beaked. The seeds of the three-celled fruits, are indistinctly three-sided, and slightly angled. The seeds of the two and three-celled forms vary from astringent to astringent-aromatic. Most of the tannic acid is contained in the seed,—at least judging from the taste, one is led to believe that.

The structural variation of allspice is not of recent origin, for I found a similar variation when I examined a sample of allspice which had been placed in our museum many years ago.

## THE PHARMACOGNOSY OF THE MEDICINAL RHAMNUS BARKS.

---

E. N. GATHERCOAL, PH. G.

---

### INTRODUCTION.

*The European Group of Rhamni:*—For centuries the bark of a wild shrub, known in England as Alder Buckthorn or Berry Alder, has been used in Europe as a purgative. This bark is now recognized in most of the leading pharmacopœias of the world, under the name of FRANGULA or FRANGULÆ CORTEX. The plant yielding the drug, RHAMNUS FRANGULA, (*Linnaeus*), ranges along roadsides and in thickets over all of Europe, except the very northernmost parts and east over northern Asia.

Associated with RHAMNUS FRANGULA is RHAMNUS CATHARTICUS, (*Linnaeus*), a thorny shrub, named in England, Buckthorn or Waythorn. This plant is also found in northern Africa, India and eastern United States. The fruit, especially, has been employed for many centuries in Europe as a cathartic. It is now official in a few of the European pharmacopœias. As a medicine the fresh, ripe berries are made into a decoction or the abundant juice is expressed and made into a syrup. The juice of the partially-ripe Buckthorn Berries is yellow and

has been used for staining parchments, etc., while the juice from the ripe berries, is of a greenish-purple color and, when evaporated to dryness with lime or alum, produces the well-known water-color pigment, "sap-green." The bark, also, possesses purgative properties, which, in the fresh bark, are said to be more drastic than Frangula.

Among the other European Rhamni may be mentioned RHAMNUS INFECTORIUS, (*Linnaeus*) yielding "French Berries"; RHAMNUS SAXATILIS, (*Linnaeus*), RHAMNUS TINCTORIUS, (*Waldstein et Kitaibel*) and other species yielding "Persian Berries"; and RHAMNUS CARNIOLICA, (*Kern*) (possibly identical with RHAMNUS SAXATILIS), the bark of which has been found admixed with Frangula. These plants grow wild in southern and eastern Europe and Asia Minor. From French Berries a valuable yellow dye for textiles is prepared and from Persian Berries is obtained the dye used in staining Morocco leather.

*The American Rhamni*:—Another group of Rhamni furnishing medicinal barks, is found along the western coast of North America. With the settlement of California by the Spaniards, the new-comers noted that the native Indians used the bark of a certain kind of shrubby-tree, as a cathartic. The Spaniards named this plant and its bark Cascara Sagrada (Sacred Bark). The early American settlers used the name "Chittem Bark" (Chittam, Shittem, Shittim, Sittem), the origin of which is unknown. This drug is now official in nearly all the pharmacopœias of the world. It is obtained from the plant RHAMNUS PURSHIANA, (*DeCandolle*), which ranges over the west slopes of the Cascade Mountains, from central California well up into British Columbia, and forms extensive low forests on the valley and mountain sides.

Associated with RHAMNUS PURSHIANA, though ranging more to the south, is RHAMNUS CALIFORNICA, (*Eschscholtz*), locally known as Wild Coffee, found in central and southern California and northwestern Mexico, a shrub or small tree. Probably the bark of this plant was that originally introduced as cascara bark. It was gathered for years along with the RHAMNUS PURSHIANA bark.

RHAMNUS CROCEUS, (*Nuttall*), a shrub of central and southern California, also furnishes a bark with cathartic properties.

Another American Rhamnus which has furnished a medicinal bark is RHAMNUS CAROLINIANA, (*Walter*), of southeastern United States, commonly known as Southern or Carolina Buckthorn.

*Foreign Medicinal Rhamni*:—Little mention is made, in medical or pharmaceutical literature, of the medicinal use of Rhamnus barks from other countries. The bark of RHAMNUS WIGHTII, (*Wight and Arnott*), of India, is described by Hooper, (1888), who states that it is commonly sold in the shops of Bombay. The plant is included by Tavera, (1892), in a list of the medicinal plants of the Philippines. It is a tall shrub or small tree ranging over the higher hills and valley slopes in the forests of Western Bombay and Madras; is also found in central Ceylon and in Batangas, Philippines. The bark possesses cathartic, also tonic and astringent properties.

A specimen of the bark of RHAMNUS CHLOROPHORUS, (*Decaisne*), from China, was exhibited, in a collection of rare drugs, at the World's Columbian Exposition in 1893. Whether other lots of this bark have ever been received into the United States is not known. This plant, with another species, RHAMNUS UTILIS,

(*Decaisne*), was described and named by Decaisne, from specimens sent to Europe in 1854. Hemsley, however, claims that *RHAMNUS CHLOROPHORUS* is identical with *RHAMNUS TINCTORIUS* and that *RHAMNUS UTILIS* is the same as *RHAMNUS DAVURICUS*. Fortune, in an account of his travels in China, states that the bark and twigs of these species, mixed together, furnishes the dye long known in Europe as "Chinese Green." In China, the mixed barks are boiled with water, the liquor sopped up with cotton cloth coated with lime, and the resultant beautiful, green color washed out of the cloth. The plants were introduced into France and cultivated for the dye-stuff, but later the project was abandoned because of the high cost of production. The color is, apparently, very similar to sap-green.

#### LITERATURE AND HISTORY.

*Botany*:—The term "*ramnos*" used by the early Greek physicians and naturalists, is thought to be derived from the Celtic "*ram*," signifying a tuft of thorns or branches. The name was applied to certain thorny plants by these writers, but from their meager or inaccurate descriptions it is impossible to establish that the plants mentioned by them were any of the Rhamni as we know them to-day.

Theophrastus mentions two kinds of *ramnos*, black and white, both thorny, thus shutting out *RHAMNUS FRANGULA*, which is not thorny. Dioscorides describes three kinds: one with long, flat, soft leaves; one with white leaves, and a third with round leaves. He states that the leaves should be used in the form of poultice for erysipelas and herpes.

Pliny, the Roman physician, under the name "*rhamnos*," mentions two kinds, one whiter or lighter in color (*candidior*), and more shrubby (*fruticosior*), the branches terminating in straight thorns and with larger leaves. The other kind is darker, more of a reddish-color with curved spines and bearing a sort of pod. It is very evident that the second plant mentioned, is not a modern *Rhamnus* and while the first one has some characteristics of the *RHAMNUS CATHARTICUS*, one fails to see why it should be described as white, for the bark is black and even the flowers are greenish. Galen makes no further distinction than this one of color.

The early Anglo-Saxons were acquainted with the purgative properties of, at least, the *RHAMNUS CATHARTICUS*, for we find the plant mentioned in their medical writings before the Norman Conquest. The juice of Waythorn Berries is described as an aperient by Welsh physicians (Physicians of Myddvai), at the beginning of the thirteenth century.

Crescentius (1305), mentions *RHAMNUS CATHARTICUS* under the name *Spina Cervina* and describes *RHAMNUS FRANGULA* under the name *Azornus*, mentioning the use of the middle bark as an evacuant.

With the enlightenment appearing in natural science at the beginning of the sixteenth century, many important contributions were made to botanical and medical literature. Ruellius (1537), does not recognize *RHAMNUS FRANGULA*, but does refer to a thorny species of *Rhamnus*, probably *RHAMNUS CATHARTICUS*.

It is not until Matthioli (1548), in his commentary on the materia medica of Dioscorides, that a good description of *RHAMNUS FRANGULA*, with mention of the purgative property of bark and berries, is found in literature. He first uses

the name "frangula" in connection with the plant; (*frango, frangere* meaning "to break," an allusion to the soft and fragile nature of its wood).

Among those who describe one or both plants or refer to their medicinal properties, after Mattioli, one may mention Tragus (Hieronymus Bock) (1551), a Bavarian clergyman, who carefully illustrated and described several European Rhamni; Eucharius Rosslin (1569), a German physician, who called RHAMNUS FRANGULA "arbor foetida," from which originated the present common German name for FRANGULA, "Faulbaum"; the Dutch physicians, L'Obell (1576),—to whom is credited the specific name "catharticus,"—and Dodoens (1583), whose writings have been translated into several languages, including English, and constitute a basis for modern pharmacognosy; Dalechamps (1586), a famous French botanist, who mentions the yellow staining properties of the fresh juice of the fruit and the production of green pigment by treatment of this juice with alum; Tabernæmontanus (1588), one of the creators of German botany; Bauhin (1596), a famous Swiss professor of botany who fully describes these plants and gives the name "*Alnus nigra baccifera*" to frangula; Camerarius (1598); Gerarde (1666), the author of an English herbal and history of plants; Ray (1696), an English botanist of note, etc., etc.

By this time the botanical characters of most of the European Rhamni were well established. Linnæus (1753), places them in the *Pentandria Monogynia*. He includes both RHAMNUS FRANGULA and CATHARTICUS as natives of Sweden, in his *Flora Svecica* (1745), and mentions as pharmaceutical products derived from them: *Spina Cerdica Bacca*, *Syrupus Domesticus*, *Frangula Cortex*.

Jussieu (1787), introduced the term *Rhamna* as a generic name and Willdenow (1806), established these plants in the natural system.

The California group of Rhamni was studied by many botanists during the first part of the nineteenth century. Pursh, in 1814, described the plant RHAMNUS PURSHIANA under the name RHAMNUS ALNIFOLIUS, and it was named as a new species by DeCandolle in 1825. RHAMNUS CALIFORNICA was described and named by Eschscholtz in 1823 from specimens sent to him. This plant is closely allied to RHAMNUS PURSHIANA, if not identical with it, as has been repeatedly pointed out from time to time. (Beckett, Rusby, True and Klugh, Brandegees.) RHAMNUS CROCEUS was described and named by Nuttall, from plants seen near Monterey, California, his manuscripts being published by Torrey and Gray in 1838.

About 1850, Mayer mentions the use of Chittam Bark as a purgative among the Indians and trappers in California. Probably the Yokio and Yuki Indians of Mendocino County, California, may be credited with the introduction of cascara bark to the American settlers. These Indians used the bark in decoction—a handful boiled in about a gallon of water—as a cathartic and a kidney-remedy. The Indian name for the plant is *Hosa-kala*.

In 1877, Pandey, in a short article about *Berberis aquifolium* mentions the cathartic qualities of cascara bark and in the following year published a description of the drug and suggested its more general use as a valuable medicine.

*Collection and Commerce*.—Within a few years after 1877, Cascara Sagrada established a reputation as a tonic laxative and peristaltic that placed it in the

foremost rank of purgative medicines, and its collection became an established industry in the regions where cascara trees were abundant.

The bark, stripped from the trees during the season (April to August), when it "peels" easily, is laid, outer-side upwards, over racks placed in the open and when dry, it is broken into smaller pieces, sacked, sold to local dealers and shipped out by the car-load.

The trees soon die after the removal of the bark, and the dried wood, either of the tree cut down or standing, has been an added fire-menace to the forests.

The exact amount of frangula and cascara barks entering commerce yearly, is hard to estimate, though it is stated by Henkel that probably more than two million pounds of dried cascara bark, is consumed annually. The total consumption of frangula bark is far less in amount.

*Cultivation*.—The Cascara plant has been cultivated in Washington, D. C. (True and Klugh), in Michigan (Farwell), in Kew Gardens and in Ireland, but nowhere, as yet, for the commercial production of bark. While there have been very extensive areas of the wild growth in California, Oregon, Washington and British Columbia (Zeig), the annual destruction of trees has also been very large, so that the district of bark-collection has been gradually driven north, until now apprehension has arisen lest the entire natural growth of Cascara trees be destroyed. (True and Klugh.)

*Pharmacopæial History*.—The fruit of RHAMNUS CATHARTICUS was recognized in the London Pharmacopœia of 1650 and in later pharmacopœias, until the present day. It was official in the U. S. Pharmacopœia, only in 1820. The fresh fruit is now official in the pharmacopœias of Belgium and Greece and in the French Codex, and the Syrup, made from the juice of the fruit, in the pharmacopœias of Belgium, Germany and Switzerland and in the French Codex.

The bark of RHAMNUS FRANGULA has been recognized in the pharmacopœias of central Europe since the middle of the last century, including the Danish, (1868), Norwegian, (1870), Swedish, (1871), German, (1870), Prussian, (1862), Hanoverian, (1861), and Dutch, (1871). It was recognized in the Austrian Pharmacopœia first in 1889, in the French Codex in 1908, in the U. S. Pharmacopœia in 1880, and in the British Pharmacopœia in 1885, though it was omitted from the last edition. Neither is it mentioned in those of Croatia, Hungary, Italy, Roumania, Servia and Spain, but otherwise it is at present recognized in all the pharmacopœias of Europe and in those of the United States and Japan.

The bark of RHAMNUS PURSHIANA, first made official in the U. S. Pharmacopœia of 1890, is now recognized in the pharmacopœias of the United States and Japan, and in all those of Europe except the Finnish, and that of Portugal, which has not been revised since 1878.

None of the other Rhamnus barks have been made official in any pharmacopœia nor do any of them appear in the commerce of Europe or America except, possibly, as adulterants.

*Adulterations*.—The fruit of RHAMNUS CATHARTICUS and also the juice from the fruit, have both been repeatedly reported as adulterated. The early Edinburgh Dispensatories mention the adulteration of the fresh fruit with fruits of the Dogberry (*Cornus*) and of the Black Alderberry (*Frangula*). The juice of

the fruit was very frequently diluted with water by those who prepared it. (Quincy's English Dispensatory.)

Van Pelt, (1874), points out that the juice of *RHAMNUS FRANGULA* berries is substituted in Belgium for that of *RHAMNUS CATHARTICUS* berries. As the former juice is much inferior as a cathartic, the substitution is very reprehensible.

Unney, (1874), states that the freshly prepared juice of Buckthorn Berries has a specific gravity of 1.070 to 1.080, which, after the juice has stood for a year, is reduced to 1.035. However, four commercial samples of fresh juice gave a specific gravity about 1.005, indicating the addition of water to the extent possibly of 500%.

Adulteration of *Frangula* has apparently never been extensively practiced. The bark of *RHAMNUS CATHARTICUS* has been found admixed with *Frangula* bark, and Moser, also Mitlacher, reported in 1905 the presence of *RHAMNUS CARNIOLICA* bark in *Frangula*. The barks of several species of *Alnus*, especially of *ALNUS GLUTINOSA* (Wuerffel, 1907), have been mentioned as adulterants.

Cascara bark has been reported adulterated with *RHAMNUS CALIFORNICA* bark, but in view of the facts that the species are nearly if not quite identical; that unquestionably the *RHAMNUS CALIFORNICA* bark was the one originally employed by the Spaniards and named by them *Cascara Sagrada*; that the chemical constituents cannot be differentiated and that the gross characters of the barks as also their histological structure are very similar, it seems hardly correct to name the one an adulterant of the other. Moss in 1888, and Squibb in 1890, complain of the poor quality of the Cascara of those dates, but attribute it to bark gathered out of season and improperly cured, on account of the heavy demand and high price created for the drug. Rusby, (1890), mentions the bark of *CORNUS NUTTALLII*, as an adulterant of Cascara bark. Perrot, (1901), mentions the admixture, in Europe, of *RHAMNUS FRANGULA* bark with powdered Cascara. Miller, (1912), finds in a large consignment of Cascara a spurious bark rather uniformly mixed and present to a considerable extent. In 1913, a large consignment of bark from Europe labeled "BUCKTHORN," received at Chicago, was found to consist entirely of this same *non-Rhamnus* bark. It resembles cascara quite closely, in size, shape and external markings, but, upon closer examination, was found to be the bark of a *Prunus*. The taste is quite astringent, somewhat bitter and has a decided flavor of hydrocyanic acid and benzaldehyde. The structure is much like that of *PRUNUS VIRGINIANA* bark and the external markings also closely resemble those of unroasted wild cherry bark.

*Histology:* Moeller, (1892), places accurate illustrations of the structure of *FRANGULA* and of *RHAMNUS PURSHIANA* in his *Pharmakognostischer Atlas*. Cubanes, in 1895, refers to the histology of *Frangula* and, likewise, do Sayre, (1897), Wuerffel, (1907), Mitlacher, (1905), and Moser, (1909).

The bark of *RHAMNUS PURSHIANA* was first described histologically, by Prescott in 1879, who mentions the presence of "thick walled" yellow cells." Later, it was more carefully and fully described by Moeller, (1882), who differentiated it from *Frangula*, pointing out the presence of "stone cells" in the Cascara, and their absence from the *Frangula*.

Beckett, (1889), refers to the histology of Cascara, and so do Rusby, (1890), and Sayre, (1897), who attempt to differentiate the Cascara barks from *RHAMNUS*

PURSHIANA and RHAMNUS CALIFORNICA. They find, however, but slight points of difference, principally some distinctions in the characters of the medullary rays.

Perrot, (1900), and Miller, (1912), refer to the structure of Cascara bark in connection with certain adulterants thereof.

Kraemer, (1912), discusses and illustrates the number of cells in the medullary rays of Cascara bark, and Farwell, (1914), compares the medullary rays of RHAMNUS CALIFORNICA bark with those of RHAMNUS PURSHIANA bark, differentiating between the barks by the differences in the rays.

*Chemistry*.—The chemistry of the *Rhamnus* barks presents much of interest because from the first analysis of frangula bark by Gerber in 1828, it has been observed that the active principles are resinous in nature, difficult to separate from one another and to determine their true constitution. Even at the present day, these analyses are far from being in a satisfactory condition.

Gerber obtained, among numerous other vegetable constituents, 2.7% of yellow resinous coloring matter and 4.6% of bitter-acrid extractive, which he considered contained the active constituents. He noted that the yellow coloring matter became dark-red with alkalis.

Hubert, (1830), analyzed the juice from the fruit of RHAMNUS CATHARTICUS. He found a bitter substance, apparently the active constituent, and closely resembling the *cathartin* of senna leaves, a green coloring matter, which, in the ripe fruit is purple-red, due to the action of acids in the ripening fruit and a brown material, insoluble in alcohol but easily soluble in water.

Fleury, (1842), obtained from the unripe berries of RHAMNUS CATHARTICUS, *rhamnin* in pale yellow crystals.

Kane, (1843), isolated *chrysorhamnin* from unripe Persian berries and *xanthorhamnin* from the ripe berries. *Chrysorhamnin*, ( $C_{23}H_{12}O_{11}$ ), extracted with ether, formed golden-yellow, silky, stellated needles, sparingly soluble in cold water, soluble in alcohol and ether and in alkalis, (though much altered), and by boiling in water is changed into xanthorhamnin, ( $C_{23}H_{12}O_{14}$ ). This latter substance is extracted from the ripe fruit with boiling water and is olive-green in color.

Winckler, (1849), obtained *rhamnin* from the unripe fruit of RHAMNUS CATHARTICUS and *cathartin* from the ripe fruit. He considered that *rhamnin*, by the ripening process is converted into *cathartin* and glucose. (This is the first published evidence of the glucosidic nature of these resinous constituents of the *Rhamni*.)

Binswanger, (1849), found in frangula bark the crystallizable yellow coloring principle which was named (by L. A. Buchner) *rhamno-xanthin*, an ether-soluble amorphous resin, one or more alcohol-soluble resins, a bitter substance of resinous nature in which the purgative properties of the bark seem to lie, sugar, gum, tannin, plant acids, extractive, etc. He compared the bark of RHAMNUS CATHARTICUS with frangula bark, and found that the constituents were similar, but included also a bitter, water-soluble, crystallizable substance to which he attributed the greater hydragogue properties of the RHAMNUS CATHARTICUS bark. This principle was differentiated from the *cathartin* of senna leaves and named *rhamno-cathartin*. He found *rhamno-xanthin* also in the seeds of RHAMNUS CATHARTICUS and RHAMNUS FRANGULA. The juice of the ripe berries contained

a violet coloring-matter turned red with acids and green with alkalis, a bitter extractive, etc. The unripe berries and those also of *RHAMNUS INFECTORIUS* contained only the *rhamnin* of Fleury.

Buchner, (1853), who worked with Binswanger at Munich in 1849, obtained from the root-bark of *RHAMNUS FRANGULA*, *rhamnoxanthin* in sublimable, golden-yellow needles, very slightly soluble in water, but easily so in alcohol or ether, (especially hot), readily in solutions of ammonia and the fixed alkalis with a fine, purple-red color and in concentrated sulphuric acid with a red color. By neutralization of the alkaline solution, the *rhamnoxanthin* was thrown out as a yellow powder and by dilution of the concentrated sulphuric acid solution with water it was likewise separated out.

Casselmann (1857), obtained the resinous constituent from Frangula in crystalline form, designated it *frangulin* and decomposed it with the formation of glucose and an acid product he named *frangulinic* or *nitro-frangulic* acid.

Phipson, (1858), found *rhamnoxanthin* in the branches of *RHAMNUS FRANGULA* and of *RHAMNUS CATHARTICUS* and corroborated Buchner's description of it.

Gellatly, (1858), obtained from Persian berries, a substance which corresponded with Kane's *xanthorhamnin*, but to which he ascribes the formula  $C_{48}H_{28}O_{28}$ , and which, hydrolyzed, yields grape sugar and *rhamnetin*, ( $C_{22}H_{10}O_{10}$ ) in yellow needles nearly insoluble in cold water but soluble in alcohol or ether.

Kubly, (1866), separated from frangula bark the glucoside, which he named *azornin*, an amorphous resin and a principle similar to cathartic acid, which he had a short time previously isolated from senna leaves. The *azornin* he split into *azornic acid* and glucose.

Lefort, (1866), named *rhamnine* and *rhamnegine* as the coloring constituents of *RHAMNUS CATHARTICUS* berries.

Stein, (1868), indicated that the *rhamnine* of Fleury, the *chrysorhamnine* of Kane, the *rhamnetine* of Gellatly and the *rhamnine* of Lefort, to be the same substance in different degrees of purity, while the *xanthorhamnine* of Gellatly and the *rhamnegine* of Lefort were also identical, but the *xanthorhamnine* of Kane and that of Gellatly, were not the same substance. He stated that, undoubtedly, *rhamnetin* was identical with *quercetin*. He named as the coloring principles of Persian berries *rhamnin*, soluble in water and *rhamnetin*, insoluble in water. The *rhamnin* upon hydrolysis with dilute acids, or with the ferment present in the fruit, yielded *rhamnetin* and a sugar.

Schutzenberger, (1868), revised the formula of the *rhamnegine* of Lefort and decomposed it with the formation of *rhamnetin* and a sugar isomeric with mannite.

Faust, (1869), stated that the *frangulin* of Casselmann, and the *azornin* of Kubly, are identical, and assigned them the formula  $C_{20}H_{10}O_{10}$ . He named the acid-resin from the decomposition of this glucoside, *frangulic acid*.

Liebermann and Waldstein, (1876), identified *emodin* (trioxymethylanthroquinone) from frangula bark and stated that frangulic acid is probably *emodin*.

Liebermann and Hornmann, (1878), found *rhamnoxanthin* in the pericarp of the berries of *RHAMNUS INFECTORIUS* and determined that, under the action of a ferment, it splits into *rhamnetin* and *isodulcite*.

Prescott, (1879), was the first to analyze cascara sagrada bark. He found

a brown resin of strongly-bitter taste, colored a vivid purple-red by potassium hydrate solution, sparingly soluble in water or ether, but freely so in alcohol, chloroform, benzole, carbon disulphide and solutions of caustic alkalies, though precipitated from the latter by acids. He found also some other resins, tannin, oxalic and malic acids, etc.

Limousin, (1885), noted that the scraped surface of Cascara bark, touched with strong ammonia or potash solution, gave a fine red coloration and considered it an incontestable evidence of *chrysophanic acid*, which he declared the "resins" of Prescott to be.

Ward and Dunlop, (1887), described the enzymatic action in the berries of *RHAMNUS INFECTORIUS*, but found that no such action took place in the fruits of *RHAMNUS TINCTORIUS*, *CATHARTICUS*, *CAROLINIANA*, etc.

Meier and Webber, (1888), mentioned in addition to other constituents found in *RHAMNUS PURSHIANA* bark, an enzyme, to which they attribute the griping effects and the epigastric pain sometimes accompanying the use of the drug, especially of the fresh bark.

Eccles, (1888), found minute quantities of an alkaloid present in Cascara fluid extracts. He also examined twenty prominent drugs by treating the ethereal extracts obtained from fluid extract, with ammonia water and found that the ethereal extracts from frangula and cascara barks alone assumed a red color. He did not distinguish between them.

Schwabe, (1888), found frangula to yield *frangulin* 0.04%, and *cmodin* 0.1%. He corroborated the physical characters of *frangulin* as stated by Casselmann and Faust and amplified upon them. His proximate analysis indicated the formula  $C_{21}H_{20}O_9$ . *Frangulin*, by hydrolysis, yields *cmodin*. He found in cascara bark *cmodin* but no *frangulin*.

Hooper, (1888), examined the bark of *RHAMNUS WIGHTII*. He reported several resins, some ether-soluble, some alcohol-soluble, tannin, bitter principle, etc. From the published analyses of *RHAMNUS PURSHIANA* bark, he concluded that the two barks rather closely correspond chemically, though the former probably had a larger tannin-content. He mentions a yellow coloring-matter in the phloem layer of the bark, which assumes a brilliant red with potash.

Thorpe and Miller, (1892), corroborated Schwabe's formula for *frangulin* and determined that the sugar from the decomposition of *frangulin* was a true *rhamnose*.

Leprince, (1892), isolated a crystalline constituent from cascara bark which formed prismatic needles of a yellow color, insoluble in water, slightly soluble in chloroform but readily so in alcohol and in aqueous solutions of alkalies with a purple-red color. He named it *cascarine*.

Phipson, (1892), regarded the principle isolated by Leprince as identical with *rhamnoxanthin* described in 1858.

Perkin and Geldard, (1894), named the coloring principles of the fruit of *RHAMNUS INFECTORIUS*: *rhamnazin*, *rhamnetin* and *quercetin*.

Cabanes, (1895), reported that, in sections of frangula bark, treated with alcoholic potassa solution, the parenchyma of the cortex, medullary rays and bast, all acquire a strong red color, but that in cascara bark sections, only one or

two layers of the cortical parenchyma, the medullary rays and the five or six inner rows of bast parenchyma, take the color. Ammonia and soda solutions react the same as potassa.

Dohme and Englehardt, (1897), obtained what they declared to be the glucoside of cascara bark, *purshianin*, in dark, red-brown needles, not responding to the tests for *emodin*, nor identical with *frangulin*, but yielding, by hydrolysis, *emodin* and a sugar.

Sayre, (1897), proposed identity-tests for distinguishing between the barks of *RHAMNUS CALIFORNICA* and *RHAMNUS PURSHIANA* as follows: To 0.2 gm. of the powdered bark in a small test-tube add 2 cc. of potash, T. S. *RHAMNUS CALIFORNICA* gives a blood-red color at once. *RHAMNUS PURSHIANA* an orange-red color.

Leprince, (1899), reports cascara bark to contain *chrysarobin*, *emodin* and *chrysophanic acid*.

Aweng, (1899), presented a method for separating the glucosides of frangula, cascara and rhubarb into groups, by successive extraction with benzene, benzene and absolute alcohol, and 60% alcohol. He obtained a number of glucosides, in varying proportions, from each of the three drugs, most of them yielding, by hydrolysis, *emodin*, *chrysophanic acid* and *frangula-rhamnetin*.

Oesterle, (1899), found that *frangula-emodin* differs from *aloe-emodin*.

Perrot, (1900), stated that powdered frangula bark with alkalis, produces a deep-red color, but that powdered cascara bark gives a yellow-color and that the powders could be distinguished in this manner.

Tschirch and Polacco, (1900), analyzed *RHAMNUS CATHARTICUS* fruit and determined the presence of *emodin*, several coloring matters, a sugar, etc. The purgative action was ascribed to the *emodin*.

Jowett, (1904), found in cascara bark, *emodin*, glucose, an enzyme, fat, etc. His attempts to isolate the bitter principle, were unsuccessful, but he claimed that *emodin* was not the most important purgative principle. The enzyme, in one-gram doses, was not griping. There was practically no distinction in the chemistry of the barks from *RHAMNUS PURSHIANA* and *RHAMNUS CALIFORNICA*.

Warin, (1905), presented a colorimetric method for the quantitative determination of the *emodin* in frangula bark, by neutralizing the rose-red tint of a measured, alkaline, aqueous extract of the drug, with the green tint of a standardized, nickel salt solution. Later, he pointed out that, before this method could be applied to cascara bark or its preparations, the same must be so treated as to hydrolyse the glucosides.

Tschirch and Pool, (1908), found that the *emodins* from frangula and cascara barks were identical, that neither of the barks yielded *rhein*, but that *chrysophanic acid* was present in frangula bark. They approved Warin's colorimetric assay.

Walja Chilo and Krassowski, (1908), claim that the same coloring principles occur in the fruit of *RHAMNUS CATHARTICUS* as in those of *RHAMNUS INFLAMMATORICUS* and *RHAMNUS LAXATORICUS*. In addition the fruits of *RHAMNUS CATHARTICUS* were found to contain about 2% of *emodin* bodies.

Tschirch and Bromberger, (1911), obtain from the bark of *RHAMNUS CATHARTICUS*, *frangula emodin*, *chrysophanic acid*, *rhamnothecin*, *rhamnosterol*, glucose, tannin, etc.

Oesterle, (1911), states, regarding the oxymethylanthroquinones, that *aloe emodin* reduced, forms chrysophanic acid, but oxidized, forms *rhein*, while chrysophanic acid oxidized, likewise forms *rhein*.

Tutin and Clewer, (1911), state that the anthroquinone derivatives from rhubarb,—*rhein*, *emodin*, *aloe-emodin*, *frangula-emodin*, *emodin-monomethyl-ether* and chrysophanic acid, are derived from medicinally inert glucosides; that only *aloe-emodin* and chrysophanic acid possess purgative properties, and that most of the purgative value of the drug, lies in a non-glucosidic resin which they isolated.

Rosenthaler, (1911), presents a list of anthroquinone drugs distinguished from one another by the physical characters of their micro-sublimates and the color-reaction of these sublimates in alcoholic solution with ferric chloride solution.

Schmidt, (1912), describes *frangulin*, (*rhamnoxanthin*), ( $C_{21}H_{20}O_8$ ), as occurring in lemon-yellow, glistening, fine needle-crystals, odorless and tasteless, melting at  $228^{\circ}$  to  $230^{\circ}$  C. It is almost insoluble in water and in cold ether, but soluble in 180 parts of 80% hot alcohol. Concentrated sulphuric acid dissolves it with a dark-red color and with caustic alkalis it forms solutions of a purple-red color. By boiling with an alcoholic solution of hydrochloric acid, it becomes converted into *rhamnose* and *frangula-emodin*, ( $C_{15}H_{10}O_5$ ), which forms bright-red, glistening needles melting at  $255^{\circ}$  C. It is insoluble in water, slightly soluble in alcohol and easily in chloroform and benzol. In ammonia it dissolves with a red, slightly bluish color.

(To be continued.)

---

## A NEW METHOD FOR THE ESTIMATION OF GLYCERIN IN PHARMACEUTICAL PREPARATIONS.

---

C. H. BRIGGS, M. S.

---

Glycerin is one of the most common and generally used substances in pharmacy and yet its quantitative determination in pharmaceutical preparations presents many difficulties. On several occasions in our laboratory it has been necessary to attempt to assay for glycerin such preparations as elixirs, tooth-pastes, shaving soaps, liquid face creams, and essences of pepsin, and the results have been far from satisfactory. Several methods with necessary modifications to adapt them to the particular preparations were tried, but in some cases the duplicate results showed marked variations, thus making doubtful the reliability of the process.

The official methods for the determination of glycerin in wines are not applicable to all pharmaceutical preparations because of interfering substances and, to say the least, they are long and tedious. (See Allen's Organic Analysis Vol. I, page 167.)

It would seem therefore that a simple and reliable method for the estimation

of glycerin, applicable to all pharmaceutical preparations, is much to be desired. For pharmaceutical purposes it is not necessary that the method shall be extremely accurate, for if the results do not vary more than 2% from the actual glycerin content, this will meet all practical requirements.

Pharmaceutical preparations contain such a wide range of substances such as sugars, salts, organic acids, soaps, proteids, resins, colors, etc., that it is almost impossible to separate the glycerin in a pure condition by means of solvents and precipitants. It occurred to the writer that perhaps the glycerin could be separated from many of these substances by distillation in a vacuum, provided some liquid could be added with which the glycerin is not miscible and which would also distil and help carry over all of the glycerin. Glycerin boils at 162° C. at 10 m. m. pressure, but by the law of partial pressures, it will vaporize at a lower temperature if distilled with some substance with which it is not miscible. After the trial of several substances it was found that santal oil was best adapted for this purpose, and that, if a small amount of glycerin was distilled with a relatively large amount of santal oil, the glycerin was completely carried over. It was also found that the glycerin could be readily separated from the santal oil in the distillate by dissolving the oil in purified petroleum benzine and washing out the glycerin with small quantities of water in a separatory funnel. The glycerin in the combined aqueous solutions could then be estimated by various methods, but the writer prefers evaporating off most of the water at a low temperature and completely dehydrating the glycerin in a vacuum over sulphuric acid. This procedure has not been noted elsewhere in the literature.

The glycerin used in these tests was of the ordinary U. S. P. grade and when about two grams were dried in a vacuum over sulphuric acid for 24 hours, it lost about 3% of moisture. Water was then added and the solution evaporated to a thin syrup at about 50° C. After drying for 24 hours in a vacuum as above the same weight of anhydrous glycerin was recovered, showing that none had been lost by the dehydration.

Two determinations by the above distillation method of a 20% solution of glycerin in water gave 99.3% and 100.8% of the glycerin, showing that where there are no interfering substances the method works satisfactorily.

The method was next tried on a mixture containing 10% of sugar and 10% of glycerin. Three determinations gave 110, 109 and 108% of the glycerin taken. A test with Fehling's solution showed that some of the sugar was decomposed and carried over with the distillate. The addition of a small quantity of slaked lime to the distillation flask prevented the sugar from going over but it also held back part of the glycerin. Calcium carbonate did not prevent the sugar from being carried over but calcined magnesium oxide worked better and three determinations of the glycerin in a solution containing 20% of sugar and 20% of glycerin, using one-half gram calcined magnesia, gave 100.1%, 101.5% and 99.9% of the glycerin content. The use of more magnesia did not work as well.

In order to test the method on products containing various ingredients, samples

were prepared of six preparations of widely different character. The amount of glycerin found was as follows:—

	Glycerin used	Glycerin found
Elixir Gentian Glycerinated N. F.	50%	49.4% 48.9%
Tooth Paste	50%	48.1% 48.6%
Shaving Soap	25%	27.6% 26.7%
Essence of Pepsin	20%	18.8% 19.7%
Elixir Lactated Pepsin	10%	10.5% 11.4%
Stearic Acid Cold Cream	8%	7.2% 8.1%

While these results are not as accurate as the writer at first hoped for, still considering the wide range of the preparations, the results are fairly satisfactory as they give a good indication of the amount of glycerin present and probably accurate enough for all pharmaceutical purposes.

The method is not applicable without some modification to preparations where there is a large amount of sugar and a small amount of glycerin, as some of the sugar decomposes and is carried over. One test was made on such a preparation by repeating the distillation and the result was slightly low.

The length of time required to complete a test by this method is about two days, but four or five tests can be made per day, so that the actual time consumed is about two hours per assay.

The apparatus found most convenient for this assay consisted of a 500 cc. distillation flask with the side neck bent so that the flask would be inclined to an angle of 45° when in use. The top of the flask was cut off to within 1½ inches of the side neck, and the flask was closed with a rubber stopper fitted with a glass tube drawn to a very fine capillary. The flask was connected to an ordinary straight tube condenser, the side neck being inserted well into the condenser. For a receiver an 8 oz. Squibb separatory funnel was used and the end of the condenser was bent slightly and inserted into the large end of the separatory funnel so that the funnel rested horizontally. This enabled the vacuum to be connected to the small end of the separatory funnel and at the same time allowed the funnel to act as a receiver for the distillate.

The method in detail is as follows:—

Take sufficient of the sample to obtain about two grams of glycerin and place in the 500 cc. side neck distillation flask with one-half gram of calcined magnesium oxide. Warm on a steam bath for five minutes. Now add 75 cc. of santal oil and distil in vacuo until about two-thirds of the oil has been distilled. Rinse the

condenser with about 100 cc. of purified petroleum benzine and add to the distillate. Now rinse the condenser well with 5 cc. of water and add to the distillate. Stopper the separatory funnel, shake well, and draw off the aqueous layer into a second separatory funnel. Extract the benzine oil solution three times with 5 cc. of water to completely remove the glycerin and add to the first extract. Shake the combined aqueous extracts with 30 cc. of petroleum benzine to remove traces of oil. Allow to stand one-half hour and draw off the aqueous layer into a tared four inch petrie dish. Rinse the separator with 5 cc. of water and add to the glycerin extract. Evaporate off most of the water at a low temperature (not over 50° C.) and de-hydrate in a vacuum dessicator over sulphuric acid for 24 hours or to constant weight. This anhydrous glycerin is very hygroscopic and must be weighed quickly. To convert to ordinary commercial glycerin divide the weight obtained by .97.

The distillation must be carried out cautiously at first to prevent bumping. After the water has passed over, the distillation proceeds quietly and can be carried out rapidly. A free flame should be used and this should be held in the hand and kept in constant rotation around the bottom of the flask.

In conclusion the writer wishes to express his thanks and indebtedness to Mr. W. B. Parker, who carried out the assays and did most of the experimental work in connection with this paper.

*Scientific Department Parke, Davis & Co., August 20, 1914.*

---

### A SIMPLIFIED GLYCERIN ASSAY.

---

F. T. BRADT.

---

The object of this investigation has been to work out a simple, rapid, and accurate method of estimating the quantity of glycerin in a sample reasonably free from impurities.

The wide variation in results of assays in recent years was deemed of sufficient importance to warrant the appointment of committees in this country and Europe to study methods of analysis and recommend the ones that gave most satisfaction. As a result it was agreed that the acetin method should be the basis on which glycerin should be bought and sold, but that the dichromate method might continue to be used for technical purposes in a properly standardized form. The exact procedure to be followed in purification was described very minutely and also the actual process of assay. The dichromate method was substantially the same as that proposed by Helmer, using solid dichromate for oxidation, an excess of ferrous ammonium sulphate, and dilute dichromate solution to titrate the excess.

Many other methods, besides these two well known ones, have been suggested for the assay of glycerin, and some of them are well worth a brief review.

In 1891 Benedikt and Zsigmondy proposed to oxidize glycerin with potassium permanganate in alkaline sol. precipitate the manganese by treatment with  $\text{H}_2\text{O}_2$ ,

---

<sup>1</sup> *Zeit. Angew. Chem.*, 1891, 400-401.

add sulphuric acid, and titrate the oxalic acid formed with volumetric permanganate. The advantage claimed for this method is that butyric acid, if present, does not interfere; chemically it is little different from the dichromate method, but is lacking in the simplicity of the latter.

Five years later <sup>2</sup>Bordas suggested adding potassium dichromate (48 gm. per litre) to 5 cc. of a dilute glycerin solution until the color changed from a bluish green to a yellowish green. If the glycerin be either too dilute or too strong, difficulty will be experienced in detecting promptly the color change. Two years later Maurice Nicloux pointed out that the above method was based on the supposition that glycerin is oxidized to formic acid. He pointed out the fact that it was changed directly to CO<sub>2</sub> and water, giving as the equivalent 37.28 gms. per litre, and not 48 gms. as first proposed.

A method proposed by <sup>3</sup>Simon Zeisel in 1902 is especially interesting. He proposed to distill the glycerin with 63 *per cent.* hydriodic acid in a current of carbon dioxide. The vapors, cooled to 60°, are passed through a small wash bottle containing amorphous phosphorus suspended in water to remove iodine or hydriodic acid fumes. The isopropyl iodide formed is then passed through a four *per cent.* alcoholic silver nitrate solution and the silver iodide collected and weighed. Schultze, in 1905, in a paper giving a comparison of results by various methods, insists that this is the only trustworthy estimation in many cases.

<sup>4</sup>Chaumeil, in 1902, suggested oxidizing glycerin with iodic acid in the presence of sulphuric acid and titrating the iodine liberated with thiosulphate. Chlorides, of course, will interfere, but by a preliminary estimation a correction may be made.

The specific gravity method is recommended by <sup>5</sup>Stiepel, subtracting from the percentage found, the *per cent.* of ash multiplied by 3.33. This, of course, would only hold good in the presence of small amounts of salts. However, the method may be of marked value as a means of quick checking.

An extraction method is described by <sup>6</sup>Schukoff in which he uses a sample containing about one gram of glycerin and evaporates to a syrupy consistency on a water bath. It is then mixed with twenty grams of anhydrous sodium sulphate, and extracted with anhydrous acetone in a Soxhlet apparatus. After evaporating the acetone the residue is weighed as glycerin.

A method which at first seems very simple and satisfactory is one proposed by <sup>7</sup>Wagenaar in 1911. He precipitates copper by means of a fixed alkali in the presence of glycerin. The glycerin holds a quantity of copper in solution varying with certain physical constants. This is determined by causing liberation of an equivalent of iodine which is titrated with thiosulphate. In calculation of results an empirical table is used giving the quantity of glycerin equivalent to from one to thirty cc. of thiosulphate.

Three other methods may be just mentioned, (a) the litharge method which

<sup>2</sup> Compt. Rend., 1896, 1071-1072.

<sup>3</sup> Chem. Centr., 1902, 1424-1425.

<sup>4</sup> Bull. Soc. Chem., 1902, 629-634.

<sup>5</sup> Chem. Centr., 1904, 1626-1627.

<sup>6</sup> Zeit. Angew. Chem., 1905, 294-295.

<sup>7</sup> Pharm. Weekblad, 1911, 497-502.

gives results neither theoretically correct nor in themselves concordant. (b) The oxidation with sulphuric acid and weighing of the glycerol carbon, and (c) treatment with excess of KOH and lime at  $320^{\circ}$  and collection of the hydrogen.

Recently a modification of <sup>8</sup>Hehner's method has been proposed and highly recommended as being very practical for the ordinary laboratory routine. It is carried out something as follows:

Weigh accurately 5 gm. of glycerin and dilute with distilled water to 500 cc. Transfer 25 cc. of this solution into a 200 cc. beaker; add 40 cc. of a solution of dichromate (made by dissolving 74.615 gm. of potassium dichromate in 750 cc. of water, adding 150 cc. of sulphuric acid, and sufficient water to measure one litre at  $25^{\circ}$  C.), and 25 cc. of sulphuric acid. Cover the beaker and heat on the steam-bath two hours. Dilute the solution to 500 cc. and mix well. Remove 50 cc. to a 500 cc. flask, add 3 grams of potassium iodide and allow to stand five minutes. Dilute with 150 cc. of water and titrate the liberated iodine with N/10 sodium thiosulphate.

Each cubic centimetre of N/10 thiosulphate used indicates an excess of 0.0657 cc. of dichromate solution and each cubic centimetre of the dichromate solution is equivalent to 0.01 gm. of glycerin.

Several disadvantages have been found in working with this method. It seems to present many unnecessary complications. The number of dilutions necessary in carrying out the operation would seem to offer fertile ground for error. The use of such a concentrated solution of dichromate makes the temperature-factor very important. Hehner having shown that a variation of one degree causes an expansion of .05 *per cent.* Failure to recognize this fact might in itself introduce a very considerable error. Further, the solution used is stronger even than theory requires. Assuming that two and one-third molecules of dichromate are required to oxidize one of glycerin, then 74.5675 grams is the equivalent of 100 grams of glycerin and not 74.615 as proposed. Again, the time required for oxidation is longer than actual experiment shows to be necessary. In working with glycerin, slow oxidation would seem to indicate oxidation of impurities, which must be avoided as far as possible. Twenty minutes was found to be ample time to completely oxidize a sample of glycerin by this method. A further complication is introduced by the use of 50 cc. for the final titration when it is just as easy and satisfactory to use 32.88 cc. and avoid the use of a factor in the final calculation.

With these facts before us, then, we suggest a simple modification of the proposed dichromate method. The process is as follows:

Weigh out accurately 5 grams of glycerin, dilute to 100 cc. and take exactly five cc. (equivalent to 25 milligrams of the glycerin) for titration. Add 50 cc. of N/10 potassium dichromate solution, 25 cc. of sulphuric acid, and heat on a steam bath for 20 minutes. Cool, add one gram of potassium iodide, and after standing 10 minutes, dilute with 150 cc. of water. Titrate the liberated iodine with N/10 sodium thiosulphate and calculate the percentage of glycerin.

Comparative results show this method to be very satisfactory. It is simple, rapid, and reasonably accurate. The dichromate solution is one that every laboratory uses constantly and so the making of new solutions is avoided. Although

<sup>8</sup> Analyst, 1901.

the solution is much more dilute than the one proposed, still twenty minutes is ample time to completely oxidize the glycerin.

We tried checking our results by means of the specific gravity method and found that it may be feasible with certain cautions. First, there seems to be a surprising lack of complete glycerin specific gravity tables, and in those we have, there is a question concerning the accuracy of the expansion factor for dilute solution. On the other hand, if concentrated glycerin solutions are used, temperature becomes very important, an error of  $0.1^{\circ}$  in reading causing an error of nearly 0.15 *per cent.* in the amount of glycerin. But using a solution of from 60 to 80 *per cent.* glycerin and being very careful in reading the temperature a reasonably accurate check may be obtained for the oxidation method.

The following results give a fair comparison of the two methods, showing how they may be used as comparative methods.

## SPECIFIC GRAVITY METHOD.

WATER	COMMERCIAL GLYCERIN	TEMPERATURE	CORRECTED SP. GR.	PERCENT OF GLYCERIN
14.8920 gms.	23.7315 gms.	$80^{\circ}$ F.	1.1526	95.08
20.1857 gms.	19.2522 gms.	$82^{\circ}$ F.	1.1194	95.14
20.0300 gms.	10.2064 gms.	$82.7^{\circ}$ F.	1.0809	95.02
.....	31.113 gms.	$85.1^{\circ}$ F.	1.2537	95.20
Average.....				95.11

## DICHROMATE METHOD.

N/10 THIO. CORRECTED	N/10 DICHROMATE	PERCENT OF GLYCERIN
19.58 cc.	49.40 cc.	95.36
19.56 cc.	49.40 cc.	95.39
19.60+ cc.	49.40 cc.	95.23
19.53 cc.	49.40 cc.	95.49

Average .....95.37%

## DISCUSSION.

MR. VORISK:—I would like to ask the second speaker about the titration of that liquid after the oxidation has taken place,—What indicator is used?

MR. BRADT:—Simply use potassium iodide and the iodine liberated is titrated with thiosulphate, using starch as indicator. The color changes from blue to green.

## THE NECESSITY OF A METHOD OF ESTIMATING THE INTRINSIC VALUE OR ESSENTIAL QUALITIES OF COFFEE.

L. E. SAYRE.

It has always seemed to the writer that the references in formularies, such as our National Formulary, in specifying the commercial or geographical brand of coffee, are made with a definiteness which is rather superfluous. To say, for example, that a coffee must come from Java and Mocha is a rather excessive discrimination. This will appear when it is shown that there are other brands than Java and Mocha (usually specified) which will give to coffee preparations equally fine flavor peculiar to the roasted berry. It is true that Mocha and Java coffees have a fine flavor widely esteemed, but Santos coffees for example, are immensely popular among American consumers and are

said to be fast supplanting the milder growths of other countries, the finer grades being invariably smooth and pleasing in liquor and flavor, possessing all the essentials of fine coffee. In point of quantity, it is stated by coffee dealers that Brazil heads the list of coffee producing countries, its annual product ranging from 7,000,000 bags to 8,000,000 bags of 130 pounds each, 75 *per cent.* of which is exported to the United States.

To give some idea of the brands or grades of coffee which are distributed in the Middle West, we give the following tabulated statement of one of the largest coffee distributors in that section.

PRINCIPAL BRANDS AND VARIETIES OF COFFEES SOLD IN WESTERN MARKET.

<i>Commercial Classification.</i>	<i>Variety or Grades.</i>
Mandheling	33
Java	24
Mocha	Many
Buckaramanga	20
Bogota	20
Maracaibo	20
Guatemala	20
African Java	10
Peaberry from Mexican Rio and Santos	Number almost indefinite
Santos, Bourbon	Number almost indefinite
Rio	Many grades
Victoria	5

Botanically speaking, the genus known as *Coffea* is divided by botanists into some sixty species, of which fifteen are referred to Africa, seven to Asia and about twenty-two to America; but there is abundant reason for supposing that the majority of these so-called species are but mere varieties, a single genus, due to different conditions of soil, climate and cultivation.

According to some botanists, there is but one genus and species of the coffee plant, *Coffea Arabica*. Others again contend that there are two separate and distinct species, classed as *Coffea Orientalis* and *Coffea Occidentalis*. While admitting but one genus, the difference in size, appearance and product being attributed by them to a variation in the soil, climate, and method of cultivation. There are three principal varieties, however, readily distinguished and recognized by those who have much to do with it and are known to commerce as *Coffea Arabica*, *Coffea Liberica* and *Coffea Maragogipe*, lately discovered in Brazil, all of which, or their transplants, furnish the coffee of the market.

It happens to fall to the lot of the Drug Laboratory of the University of Kansas, to examine, for the state, samples of coffees sent in by inspectors. No attempt is made to report on the quality, such as flavor, or commercial value, because of the entire absence of reliable tests, such as would stand in the courts, but enough experience has been gained to make the statement that there are a great number of brands and blends which furnish as fine a flavored preparation as that of Java and Mocha. For example, we have received during the past year an invoice from the Jamaica coffees which are grown in the upland and those which are grown in the lowland. Those from the upland, when properly roasted

are of as elegant a flavor as that from Java or Mocha. The same may be said of the best brands of Santos coffee. Theoretically, therefore, it is unnecessary to confine, for pharmaceutical purposes, coffees to those of the definite geographical origin usually stated.

The quality of coffee, i. e., the "æsthetic" quality, which we find in the flavor or aroma, is not due to the caffeine or the caffeeo-tannic acid content, and, indeed, to no one of the principles which are usually included in the so-called official analyses.

Most any one who is familiar with the different brands of coffee acknowledge that Mocha and Java have very agreeable and "fine" flavors as above stated, but an analyst would be brave who would go before the courts and attempt to prove that they were worthy of this distinction, from the results of the "cup test," for example. That is to say, there is no scientific data which may be regarded worthy of the attribute "accuracy" which can be offered as evidence or proof of relative qualities,—"good," "better," "best," or "poor," "fair" or "fine."

Those who have followed the literature upon this subject no doubt are familiar with the fact that the so-called aromatic or æsthetic properties were contained in the volatile principles which may be recovered by sublimation or distillation.

One report upon this, made some years ago (Merek's Report, 1907, page 61), stated as follows regarding a sublimation test: Operating upon 500 grams, it was stated that "only a few drops of a colorless liquid were obtained in a second receiver. This product suggested an odor akin to capronic acid, mixed with a trace of valeric acid. It was acid in reaction, very powerful and penetrating, diffusing very rapidly in the air, and when thus very highly diluted, gave the pronounced odor of coffee. The condensed liquid, in the first receiver was of a yellowish brown color and had a rather acrid and ammoniacal odor; it also, when diffused, suggested the odor of coffee." It was then stated that the characteristic aroma developed in the roasting of coffee is due possibly to a mixture of organic acids and compounds of phenolic origin. Erdmann, in the *Berichte der Deutschen Chemischen Gesellschaft*, 1904, refers to the oil of coffee which has been obtained by treating roasted coffee with steam. The yield from 150 kilos of roasted and ground Santos coffee was 83.5 grams or 0.0557 per cent. of an oil of brown color, of a specific gravity of 1.0844, and strong odor of coffee. On distillation of the oil, the greater portion passed over between 150° and 190° C. in the form of a light colored oil. This contained furfur alcohol and much valeric acid.

In connection with the process of roasting, it is worthy of note,—First, the effect of roasting of coffee produces, by partial carbonization and partial caramelization, a number of insoluble constituents and an equal number, perhaps, of soluble ones, which have a definite relation to the flavor of the coffee. But the quantitative relationship of the æsthetic qualities seems impossible to make, partly because of the very minute quantity of the aroma-containing constituent; the so-called caffeeol, which is produced by roasting, does not often exceed .06% and thus far we have no easy means for estimating this quantitatively. From an ordinary infusion or decoction, this aromatic principle can be washed out by means of chloroform. On the evaporation of the chloroform, the caffeine crystallizes out and the chloroformic residue, when washed with ether, yields a substance which

has the aroma of coffee and also the bitter flavor, and this peculiar flavor differs according to the brands, or blends, of coffee. Yet, this process, usually followed with a chemical process designed to give quantitative results, can be regarded as of qualitative value only. It would be interesting to have the chemical nature of these bodies definitely stated but statements thus far made give only a suggestion of their possible composition.

Recently, valuable papers have been published, which bear upon this subject, of the volatile products of coffee. One of special interest was published in the *Bulletin General de Therapeutique*, Sept 15, 1913, by M. I. Burmann, who states, in substance, that the volatile "toxic" principle in coffee is not caffeine, but lies in the associated principles of that alkaloid; that "decaffeinated coffee is as noxious as the caffeinated," and that an "atoxic coffee" is one that has these toxic principles removed. These, he finds to be the volatile principles and separable by distillation.

An aqueous distillate is collected in refrigerated ether. The ether separated from the aqueous distillate and the ethereal layer dried by means of calcium chloride. The ethereal solution is then distilled under diminished pressure and the noxious principle, in very small percentage, is left behind in the residue. This principle, which the author terms, "caffeo-toxine" is a colorless, refractive liquid which soon decomposes into a yellow and finally to a black color. This principle, the author refers to as of phenolic, aldehydic or ketonic character.

In an abstract of an article by G. Bertrand and G. Weisweiler, published in the *Analyst*, Sept., 1913, p. 417, the volatile principle of coffee is referred to as a "pyridine-like body." This statement seems to agree with the results which we have obtained in our laboratory.

Burmann, in extracting the volatile principle, made use of 10 kilograms of the finely ground roasted coffee, which was distilled with steam until about 30 liters of distillate were obtained. This was extracted with 10 liters of pure ether, etc. It is unnecessary to point out that such a process would be impracticable for any routine analytical procedure. But the necessity for estimating chemically the essential qualities of coffee becomes urgent and apparent when we remember the present loose and inadequate commercial classifications based on purely geographical data.

Doctor C. F. Nelson and myself have endeavored to find reagents that will determine quantitatively the constituents above named, i. e., the tannin-like bodies, which belong to the polyphenols, and the pyridine-like bodies, and to make these determinations by "micro-chemical" methods.

We are encouraged to believe that we may be able soon to furnish data concerning these two constituents by means of both colorimetric and "nephelometric" methods. We are at present working with the color reaction, produced by phosphotungstic acid, which we have found, thus far, to be extremely delicate. By this method a quantitative accuracy of five parts per million seems to be attainable.

To say the least, this topic opens up an interesting question. The recent investigations point also to a correlative one which has a bearing on the dietetic problem in connection with the beverage.

If it can be proven that this volatile principle is toxic, it is detrimental to public

welfare to place a high value, commercially, on that which is injurious physiologically. If we estimate a coffee in proportion to the amount of the toxic ingredient, this is not in harmony with the principles regulating the value of dietetics.

Finally, if the pyridine-like body is developed by the roasting process, does not the same principle develop in the roasting of cereals and in chicory? Our experiments seem to indicate that this may be true.

#### DISCUSSION.

MR. WM. C. KIRCHGESSNER:—I would like to ask, if I may, if you cannot estimate the value of the coffee by the caffeine content?

PROF. SAYRE:—You cannot estimate the value of coffee by the caffeine content. You can sometimes obtain a very high caffeine content from cheap coffee, and from a very expensive coffee you may get a very low yield in caffeine content.

MR. KIRCHGESSNER:—Why is it that all the Decaffa Coffees are so dark? I have had men who make it a business of roasting coffee tell me that they could produce Decaffa Coffee at the same price that any other coffee could be sold. They would put the coffee in a roaster, tighten the cap and apply heat and after the coffee was roasted for a certain length of time let the roaster cool, cap up. After taking off cap a dark brown powder would adhere to the top of the roaster which they claimed was the caffeine. I got some of this coffee roasted in this way and the people who used it said that they could not see or taste any differences from coffee which they paid twice as much for.

PROF. SAYRE:—I suppose you know that roasters of coffee always expect a loss in caffeine in the process of roasting. This constituent is sublimed to a greater or less extent in the operation and it is well known that the crude caffeine collects on the walls of the coffee roasters and this sublimate is very valuable because of its caffeine content,—because of its richness in this alkaloid.

PROF. KREMERS:—I would like to ask whether the acid gives the aroma to the coffee, or aromatic residuum?

PROF. SAYRE:—It is given by the so-called oil which is associated with pyridine. The pyridine like constituent is associated with the aromatic principles or is a part of them. Dr. Nelson has been working with me on this problem. He is at Harvard during the summer and he hopes in the fall to work out the final result as to this toxic constituent which is present only in very minute quantities. We find it has a very close connection with the aromatic or so-called toxic principle.

PROF. KREMERS:—Do you know of any pyridine content, so-called that is suggestive of the aroma of coffee?

PROF. SAYRE:—No, I do not. It is well known that pyridine *itself* is not suggestive of coffee. But it is well known, however, that you can modify odors by certain combinations, especially when they are present in minute quantities.

---

#### THE ASSAY OF OPIUM.

---

A. R. L. DOHME.

---

There is no more important nor more frequently used assay process in the pharmacopœia than that of opium. There is no drug used in which the monetary value of variation in assay results is greater, for above all other drugs the price of opium is directly determined by and based upon its assayed strength of morphine. There is hence every reason why this assay process of all processes in the pharmacopœia should tell the truth or as nearly the truth as is possible. Hence the great question before the Revision Committee is the process of assay for opium and again this committee is confronted as it was in 1904 by two opposing factions favoring respectively the U. S. P. method which exhausts the opium by water and the lime method which exhausts the opium by the use of lime. Manufacturers of morphine probably know best the relation of assay of drug to yield of manufacture because

they are getting comparative data along this line all the time. It is admitted that about one *per cent.* of morphine is lost in manufacture whether it be in exhausting the opium for making fluid extract, tincture or morphine salt or by oxidation or other change. I have convinced myself that this loss is not due mainly if at all, to incomplete exhaustion as delicate qualitative tests for the presence of morphine in exhausted drug indicate the absence of morphine in practically all instances. Rather is the loss in my opinion due to oxidation or other chemical change of the morphine in the process incident to the exhaustion of the drug or manufacture of same into its respective preparations.

This view is taken by Debourdeaux, (*Jour. Pharm. Chim.*, 1912, *II*, p. 491) who found that opium is subject to change when stored for any great length of time. The content of water soluble morphine or morphine salt is increased due to some chemical change in the mass.

It is generally admitted that the present U. S. P. opium assay leaves morphine in the mother-liquors which I have been able not only to detect qualitatively but quantitatively by extracting it with immiscible solvents and determining it volumetrically by a process of assay devised by my laboratory, and to be described below. If you know that by the lime process you obtain from an opium 10 *per cent.* of morphine; by the U. S. P. process, as modified by the present Revision Committee, 11.5 *per cent.*, and by our method 12.3 *per cent.* of morphine and if you know by your own test that the lime-process mother-liquors contained about 2.25 *per cent.* of morphine; the U. S. P. method mother-liquors contained about one *per cent.* of morphine and the mother-liquors from our process contained practically no morphine, would you hesitate about voting that the lime method is the best method to be adopted for the pharmacopeia? Yet this is the condition that confronts us all as users of the pharmacopeia, for a majority of the proximate assay committee after once adopting the U. S. P. method by a practically unanimous vote reconsidered their action on the motion of one member and then adopted the lime method of Prof. Stevens, the chairman of the committee, by a vote of 5 to 3, with one member not voting. To be sure, the lime method result above given represents the morphine actually obtained and weighed, to which by the proposed method of assay to be made official in the U. S. P. is to be added 1.12 *per cent.* as a correction factor, making the result 11.12 *per cent.* Kindly remember that they do not and did not propose to add a correction factor to the result obtained by the U. S. P. process, although any one can prove, as we have done, that there is 0.75 to 1 *per cent.* of morphine left in the U. S. P. mother-liquors. If the committee sees fit to use a correction factor at all, and personally I think it unwise and unscientific as it admits weakness and error on its face and hence induces doubt, should they not, in their comparative assays in justice to the public and the process have used a correction factor for the U. S. P. method? In that event the comparative figures would read, using the same opium: -

Lime method 11.12 *per cent.* morphine.

U. S. P. method 12.25 *per cent.* morphine.

In 1904 the same thing occurred, and I, as chairman of the committee, appealed the matter to the General Revision Committee of twenty-five. Both myself and Prof. Stevens presented arguments and figures to substantiate our positions and the General Revision Committee supported me by a vote of 16 to 9 and

the U. S. P. method and not the lime method became official in the U. S. P. and has been for ten years. At that time and at this time Prof. Stevens censured me for going outside the committee and giving any results or facts of the committee's work to the General Committee or the public. I do not, however, favor star chamber methods in anything and never have, and feel to-day that every result or piece of work done by the Assay Committee or any other sub-committee of the U. S. P. Revision Committee is the property of the general public and should be made known by publicity to that public. I am sure there is no result, work or vote standing over my name in the files of the Revision Committee during the fourteen years I have been a member of it that I am not willing and glad to have made public and, further than that, I do not propose to remain indifferent and let a process of assaying opium that I consider to be inferior be adopted as the official and legal opium assay process for this country by a small majority of a committee. I propose to fight for what I feel convinced is right until I am convinced by incontrovertible arguments that I am wrong and that privilege I am only too glad to grant to any of my worthy opponents.

In the practical part of this paper I have had the kind assistance of Messrs. H. Engelhardt and O. E. Winters of my laboratory.

For the assay of opium 80 different methods have been recommended, many of which, naturally, have only doubtful value. Most of these methods depend on a crystallizing process, that is, the opium is extracted by a suitable solvent and from the solution either as such or in concentrated form after the addition of an alkali, the morphine is allowed to crystallize. In about 50 (that is about 65%) of these methods water is used as a menstruum and from the aqueous solution after the addition of alcohol or ether or acetic ether or a mixture of these and a slight excess of ammonia water the morphine is allowed to crystallize. In about 14 (that is about 18%) of these methods the opium is extracted with lime water, the calcium salt of morphine thus obtained is decomposed by ammonium chloride and the liberated morphine is allowed to crystallize in the presence of alcohol or ether, or of both. The extraction of opium by lime water has several decided advantages, viz:—calcium hydroxide does not dissolve the greater majority of the opium alkaloids such as narcotine, narceine, etc., as well as meconic acid, and by its use many of the resins present in the opium are eliminated. These, however, do not overcome its several disadvantages, the principal one of which is that it does not extract all or as much morphine from opium as the other methods. I may have the most perfectly devised and scientifically accurate method of assaying gold in copper or nitrogen in the air, but if it yields me less than is actually present or is determinable by other methods it has little practical value to the chemist.

Other methods depend on the property of morphine to be easily oxidized and in them certain reagents which are added to the morphine solution are reduced and the reduction products determined volumetrically.

In other methods, the morphine is estimated either colorimetrically or polarimetrically or with potassium-mercuric iodide solution.

The methods in which the morphine is allowed to crystallize have the one great disadvantage, to wit, that, *with the exception of that of the U. S. P.*, the morphine

is allowed to crystallize from too dilute solutions. It is a very well-known fact that morphine is not entirely insoluble in water or in diluted alcohol or in mixtures of water, alcohol and ether, especially in the presence of an alkali. This solubility is naturally materially increased by the presence of resins and is also dependent on the temperature at which the crystallizing liquid is allowed to stand. In most of these methods the proportion of opium to aqueous liquid is about 1 : 10, while in the U. S. P. method the proportion is only 1 : 5; naturally the results obtained by the latter method are considerably higher than those obtained by the other methods, because less morphine is lost by solubility in the mother-liquors.

Experiments to shake out the morphine with a suitable immiscible solvent such as hot chloroform, amyl alcohol, etc., have repeatedly been reported. By these solvents, however, a great amount of the resins is extracted from the opium also, which render the final titration extremely difficult. About four years ago the chemists of the Bureau of Chemistry at Washington worked out some methods by which the morphine was extracted at first with a mixture of alcohol-chloroform and then with chloroform alone. These methods are rather complicated and have to be adhered to in every detail, but the results are quite satisfactory. The shaking out of the morphine is a very tedious process, inasmuch as at times nearly 20 shakings with the solvent are necessary to remove all the morphine from the solution. Later on, Buchbinder recommended shaking out the alkaloid from the alkaline solution with chloroform containing 5 *per cent.* of alcohol. By this modification the shaking out process is shortened considerably.

In 1912, Anneler (*Archiv. der Pharmacie CCL*, page 187) reported on some experiments made in order to estimate the morphine in pantopon, which is a mixture of the various opium alkaloids in the form of their hydrochlorides. He recommended using a mixture of equal volumes of isobutyl-alcohol and chloroform, having found that 100 parts of such a mixture dissolve 1.7 parts of morphine. This menstruum is without doubt the most convenient solvent for morphine, and since the publication of this article we have applied this mixture exclusively in control assays for estimating morphine both in opium, in galenical preparations of opium, in pills, tablets, elixirs, etc., containing morphine. This shaking out process, like all other processes of this kind, has one great advantage over the crystallization process in that by it the total amount of morphine present in the drug or in the preparation is determined, there is no aliquot part feature; at the same time the assay process is a very rapid one and can be carried out, for instance in the case of opium, easily within about five hours. The details of the process which I apply are the following:—

#### POWDERED OPIUM.

Four gms. of the powdered opium are macerated with water in the regular way either by allowing to stand over night or by shaking for three hours, then exhausting the opium with water and evaporating the combined filtrate and wash-water to about 50 cc. The solution is then transferred to a separator, made decidedly alkaline with caustic soda solution or caustic potash solution which holds the morphine in solution as alkali morphinate. The solution is then shaken out with several portions of 20 cc. each of ether in order to remove the alkaloids of opium other than morphine, which are present in the free state. The alkaline

solution is then acidulated with sulphuric acid to convert the morphine into morphine sulphate, made again *slightly* alkaline by the addition of ammonia water and is then extracted by adding several portions of a mixture of equal volumes of chloroform and isobutyl-alcohol, until all the alkaloid is removed. The isobutyl alcohol-chloroform solutions are then filtered into a distilling flask, the filter paper washed with fresh isobutyl alcohol-chloroform, the chloroform distilled off under ordinary conditions and the isobutyl-alcohol later under diminished pressure. If the original mixture is distilled under diminished pressure bumping very frequently takes place. This can be avoided by first distilling off the chloroform under ordinary pressure. The residue in the flask is taken up in an excess of standardized acid; the acid solution is well diluted with water, and, after the addition of a few drops of methyl red, the excess of acid is titrated back with standardized alkali. From the amount of acid used, the morphine is calculated volumetrically.

For the assay of *Gum Opium* the following modification should be used: 20 gms. of opium representing an average sample of as many balls is exhausted in the regular way by means of water, the combined aqueous liquids are made up with sufficient water to obtain 500 cc., and 100 cc. of this solution are subjected to the assay process. Thus a fairly representative sample of the opium can be obtained. We append below some comparative results on the same drug by the two methods.

*Gum Opium U. S. P. Method*

Sample I 11.34%

Sample II 11.37%

*Powdered Opium U. S. P. Method*

Opium A 12.24%

Opium B 11.7 %

*Gum Opium Shaking Out Method*

Sample I 12.89%

12.80%

Sample II 12.35%

12.29%

*Powdered Opium Shaking Out Method*

Opium A 13.86%

Opium B 13.25%

The assays were made in duplicate by two chemists. In order to find out whether or not the method works in the hands of a worker entirely inexperienced with the method, the opium assaying 12.24 *per cent.* of morphine by the U. S. P. method was estimated by this chemist who found 13.58 *per cent.* of morphine, a figure not varying too much from 13.86 *per cent.* as found by the other two chemists.

AS APPLIED TO TINCTURE OF OPIUM.

From 25 cc. of the tincture, the alcohol is expelled by heating; the residual liquid acidulated with sulphuric acid, the solution filtered into a separator and the filter and residue washed with small portions of water until the combined filtrate and wash-water measure 50 cc. This is then treated as the concentrated aqueous extract in the powdered opium assay.

By this process the following comparative results were obtained on the same laudanum sample:—

*U. S. P. Method*

1.23% morphine

*Shaking Out Method*

1.33% morphine

I have frequently applied the shaking-out method for estimating the morphine in unfinished tinctures of opium, i. e., the strong tincture before being diluted to

the standard. From the amount of morphine obtained I deducted 10 *per cent.* (approximately the amount found in excess over the U. S. P. method by the shaking-out method) and according to the difference thus obtained I diluted the tincture. I invariably found that the tincture thus diluted answered the requirements of the U. S. P. very well. This procedure has saved us a great deal of time in the course of the year we have been using it, since the shaking-out process can easily be carried out in three hours, while the U. S. P. process takes at least 24 hours.

#### AS APPLIED TO FLUIDEXTRACT OF OPIUM CONCENTRATED.

Five cc. of the fluidextract (four times the strength of the tincture) is deprived of its alcohol by evaporation, the liquid is then acidulated with sulphuric acid and filtered into a separator. The residue on the filter is washed well with several portions of water until the combined filtrate and wash-water measures about 50 cc. The assay is then carried out as in the case of the tincture.

#### AS APPLIED TO FLUIDEXTRACT AND TINCTURE OF OPIUM CAMPHORATED.

The isobutyl alcohol-chloroform method is especially useful in assaying preparations containing only a small amount of opium such as fluidextract of opium camphorated and paregoric. For assaying the fluidextract 25 cc. are used and 50 cc. for estimating the morphine in paregoric. The process is almost identical with that given under fluidextract of opium. Most of the benzoic acid and camphor is eliminated on evaporation and filtering. Any benzoic acid left in suspension does not interfere with the estimation. I append a few results obtained in assaying these camphorated products.

#### FLUIDEXTRACT OF OPIUM CAMPHORATED.

(Eight times the strength of paregoric without removing the benzoic acid entirely.)

Lot A 0.346% morphine (theoretical strength 0.384%)  
 Lot B 0.390% morphine (theoretical strength 0.384%)  
 Lot C 0.372% morphine (theoretical strength 0.384%)

Removing the suspended benzoic acid by first shaking out the acid alkaloidal solution with ether, I found in the same products:

Lot A 0.374% morphine (theoretical strength 0.384%)  
 Lot B 0.361% morphine (theoretical strength 0.384%)

#### *Tincture of Opium Camphorated (Paregoric).*

Lot D 0.052% morphine (theoretical strength 0.050%)  
 Lot E 0.056% morphine (theoretical strength 0.050%)

#### As applied to Extract of Opium.

0.5 gm. of the extract was dissolved according to the directions of the U. S. P., the aqueous solution was evaporated to about 50 cc. and the process was then carried out as described under tincture of opium. The results of the assays follows:

<i>U. S. P. Method</i>	<i>Shaking-out Method</i>
Lot F 18.63% morphine (theo. str. 20%)	20.1% morphine
Lot G 20.04% morphine (theo. str. 20%)	21.7% morphine

#### As applied to Tablets.

Dr. Engelhardt (*D. A. Apoth. Ztg.*, 1912, January and February), has reported in detail on the usefulness of the shaking-out method in assaying morphine sulphate tablets. We have made a number of additional experiments in this direction, and we have also assayed tablets of complex composition, containing morphine salts combined with other drugs. We have found that the shaking-out method gives rather good results with tablets containing other alkaloidal extracts, provided the alkaloids present in these extracts are soluble in ether. It would be beyond the scope of this paper to give in detail all the results which we have obtained. We feel convinced, however, that the shaking-out method is the best yet proposed for quantitatively determining morphine in tablets.

As applied to Pills.

Pills, both simple and complex, can be assayed just as conveniently as tablets. The diluents in the pill mass do not apparently interfere with the accuracy of the assay. For instance, we have applied the shaking-out process to Neuralgic, Gross, N. F. pills which as is well known contain in addition to 1/20 gr. morphine sulphate, 2 gr. quinine sulphate, 1/30 gr. strychnine, 1/20 gr. arsenous acid and 1/2 gr. extract aconite leaves. When applying the shaking-out process, described in this paper, we found the pills to contain 1/23 gr. morphine sulphate, a result which without doubt is very gratifying considering the large proportion of other alkaloids present in the preparation.

We have also applied the shaking-out process to morphine preparations containing a comparatively small amount of the alkaloid, for instance, to Elixir Morphine Aromatic which contains, in addition to several other ingredients one grain of morphine sulphate per fluid ounce. By the isobutyl alcohol-chloroform shaking-out method we found in three different lots of this .936 grain, .938 grain and .94 grain of morphine present in one fluid ounce. The shaking-out method can be applied also with advantage to other substances containing small amounts of morphine, such as poppy heads and preparations thereof.

From an experience of more than a year with the shaking-out method using isobutyl alcohol-chloroform as immiscible solvent, we cannot too strongly recommend this method and we trust that many other chemists will try this method and publish their findings or let us hear from them. It is our conviction that the shaking-out method will eventually be made official in the U. S. P. in order to save time and to estimate the *total amount* and correct amount of morphine present in the drug or in its galenical preparation without using correction factors or aliquot parts. As has been pointed out in the first part of this paper all the methods which have been recommended for the estimation of morphine give results that are too low and that vary too much, due to the varying amount of morphine remaining in solution in the crystallization liquid.

In closing, I would like to mention that we devised and worked out this shaking-out method only after most of the assay work on opium of the Proximate Assays Committee had been completed. In fact, I had practically voted to adopt the U. S. P. process as revised by the committee. When the reconsideration of this action came up, I suggested trying the shaking-out method in comparison with the other two methods before the committee, viz., the U. S. P. and lime methods. It received little or no consideration, however, the Proximate Assay Committee

being unfavorable. The stage was set for lime versus U. S. P. and no one could see the shaking-out process.

In conclusion, I think I have proved that:—

First:—The lime method is inferior in every sense, except shorter time of operation, to the U. S. P. method, and is not worthy of adoption in the pharmacopœia of this country.

Second:—That the shaking-out method devised by us is superior in every sense, will eventually be adopted in the U. S. P. and should be adopted now. If not adopted now, then the modified U. S. P. should be adopted by the Revision Committee.

Third:—That the shaking-out process is adapted to determining morphine in practically all kinds of mixtures as well as practically all forms of medication.

*Analytical Laboratory, Sharpe & Dohme, August, 1914.*

---

## THE LIME ASSAY OF OPIUM.

---

A. B. LYONS, M. D.

---

Of the numerous methods that have been proposed for the morphimetric assay of opium, two only seem to have found favor with the authors or compilers of national Pharmacopœias.

In one, the drug is exhausted with water, the solution concentrated to a small volume, alcohol and ether added together with water of ammonia, the mixture shaken well and allowed to stand for a specified time for separation of the morphine in crystals.

In the other, the powdered opium is mixed with lime and a certain proportion of water, allowed to macerate, with occasional stirring during half an hour, the solution filtered and an aliquot portion of the filtrate treated with ammonium chloride which causes the morphine to separate in crystalline form.

The advantages claimed for the second method are (1) rapidity of execution; (2) superior purity of the morphine obtained, owing partly to the fact that lime combines with morphine forming a very soluble compound—a property not shared with it by narcotine or most of the other alkaloids of opium—partly because the lime throws out of solution certain organic acids and other compounds which otherwise are liable to be thrown down with the morphine; (3) alleged uniformity of results.

Against the lime method it is urged: (1) It involves unavoidably the principle of the aliquot part; (2) crystallization of the morphine is from a more dilute solution than in the first general method, hence more of the morphine is held in solution so that an arbitrary correction is generally prescribed to compensate this loss. (It is generally admitted that there is also loss of morphine in the first assay method, in which no correction factor is generally prescribed;) (3) the assay requires that the opium be in the form of a powder, whereas

opium is imported in a moist condition, so that it must be dried (the loss of weight noted) and reduced to a powder—operations which greatly lengthen the time required for an assay.

Before entering into any discussion of these claims and counter claims, it is necessary to enter more in detail into the particular method of carrying out the respective assays. A typical lime assay process is that of the French Codex. Somewhat simpler and more familiar to American pharmacists is the Stevens assay. In the latter four grammes of powdered opium are mixed with two grammes of calcium oxide, the powder made into a paste with 10 cc. of distilled water, 19 cc. more of distilled water are added and the mixture is stirred occasionally during half an hour. The magma is then transferred to a filter and exactly 15 cc. of filtrate is taken for the assay, assumed to represent 2 grammes of the opium. To this is added 4 cc. of alcohol, 10 or 15 cc. of ether and 0.5 grammes of ammonium chloride. The mixture is shaken frequently during 30 minutes, then allowed to stand over night to complete the crystallization. The crystals of morphine are then collected in a small funnel loosely plugged with absorbent cotton, washed with morphinated water, transferred to the flask in which the crystallization process was carried out, the morphine being finally determined by titration with volumetric acid and alkali.

The first question that arises is as to the accuracy of the aliquot part taken. This will depend on the increase in volume of the fluid, due to the dissolved extract and lime. A number of experiments made with several different samples of opium have showed that where slaked lime is used, the increase in volume over 29 cc. is about 0.6 cc. covering a range from 0.5 to 0.75 cc. In the assay, the increase is taken as 1 cc. and the allowance thus made for incomplete exhaustion of the drug, amounting to from 0.8 to about 1.7 *per cent.* of the total may be considered reasonable. It is considerably less than the allowance in the assay process of the French Codex, and in other official processes. It is to be noted, however, that if calcium oxide is used instead of calcium hydroxide, this allowance is increased to 3 *per cent.* or more, since the oxide combines with and fixes one equivalent of water.

It is sometimes difficult to obtain a filtrate measuring as much as 15 cc. In such case, the filter containing the residue may be enclosed in a small piece of cheese cloth or muslin, and the residual fluid pressed out and then filtered through a small filter.

Measurement of the 15 cc. of filtrate must be made as accurately as possible—best with a measuring pipette. Of course, exposure of the filtered solution to air, particularly to the air exhaled from the lungs, must be minimized, by receiving the filtrate in a small flask, keeping the funnel covered with a watch glass and conducting the filtration as rapidly as possible to guard against any precipitation of calcium carbonate.

It is a question whether addition of any alcohol to the filtrate is advisable. Larger and whiter crystals of morphine are formed if the alcohol is added, but the separation of the morphine by crystallization under the ordinary conditions of the assay, is certainly less complete than if the alcohol is omitted. A careful study ought to be made of the influence (a) of alcohol, (b) of temperature,

(c) of the amount and kind of shaking, and (d) of the quantity of ether added. It should be understood that when morphine is set free in presence of ether or of a mixture of ether and alcohol, the alkaloid is largely transferred in the shaking to these solvents, and that at the end of the crystallization, the residual morphine will be found chiefly in the ethereal fluid.

I have found by experiment that when ether alone is used the residual morphine, after 14 hours, is almost a negligible quantity. When alcohol is present a notably larger quantity is held in solution. Whether it is possible to determine to a close approximation just how much of the alkaloid will be held in solution under prescribed conditions of shaking, temperature and time, can only be ascertained by a series of experiments. Inasmuch as the loss of morphine, where only ether is used, is inconsiderable, it seems to me unwise to use the alcohol—unless it can be shown that other alkaloids are thus prevented from crystallizing with the morphine, of which there seems to me practically no possibility.

Stevens' method of collecting the morphine and determining it by titration is neat, rapid, and I believe beyond criticism.

When the lime assay is carried out, as above detailed, the possible sources of fallacy are reduced to the following: (a) possible failure to extract the whole of the morphine by the half hour maceration; (b) possible presence in the morphine of other alkaloids; (c) possible inexactness of the aliquot part of the lime solution; (d) possible inexactness in the *titre* of the volumetric solutions used.

(a) It is not unlikely that in inexperienced hands there may be failure to extract the whole of the morphine in the initial maceration. It is my belief that if the directions for extracting the opium are carried out with reasonable care, practically the whole of the morphine will go into solution, but it is not easy to determine this experimentally. Results of comparative assays by the lime and aqueous extraction methods are not conclusive, particularly when such results have been reached in coöperative investigations.

In case it should be made to appear that powdered opium is not always completely exhausted in the prescribed routine a different procedure might be adopted in which the opium would be first exhausted with water, as in the U.S.P. assay. This, however, would sacrifice the great advantage of economy of time in the lime assay. It would, on the other hand, make the lime assay applicable to moist crude opium and with only slight modifications to all galenical preparations of opium, except the camphorated tincture.

(b) Presence in morphine separated in the lime assay of by-alkaloids could hardly be expected considering the manner in which the alkaloid is separated. At all events, alkalimetric titration indicates a high degree of purity in the crystals. The French Codex directs to wash the crystals with benzene (benzol) to remove such possible contamination. I do not think the precaution is necessary, but I have not tested the question experimentally whether benzene will reduce the weight of the crystals.

(c) The question of exactness of the aliquot, I have already considered. Of course, it is important that measurements of the water and the lime solution

should be made with exactness, and that the temperature at which these measurements are made should be practically the same, though not necessarily  $25^{\circ}\text{C}$ ., the official standard temperature.

Greater exactness can, of course, be secured by weighing the fluids instead of measuring them. If this is done a certain arbitrary allowance must be made for dissolved lime and extractive. It would be safe to make this allowance one-third the weight of the opium present, i. e., for a quantity of solution representing 2 grammes of opium, 0.667 gm. If 4 grammes of dry opium have been treated with 29 grammes of water, the aliquot representing 2 grammes of opium will be  $14.5 + 0.667 = 15.167$  grammes of the lime solution.

(d) To secure exactness in the result of the titration, it is only necessary to standardize the volumetric acid used on pure recrystallized morphine, dried over sulphuric acid. The conditions of the titration as to dilution of solution, etc., should be practically the same as in the assay; it is particularly important that the same indicator be used. For the professional chemist whose laboratory equipment is complete, there is no difficulty about so simple a matter as making an alkaloid determination by titration. In absence of such advantages a routine may be adopted which insures exact results in spite of difficulties.

One must be sure in the first place of the exact neutrality of the distilled water to be used. Put into a small flask a sufficient quantity of the water—which, although distilled, may have absorbed traces of ammonia, or if acid vapor—add a few drops of the indicator, and if necessary bring to exact neutrality by adding very dilute acid or alkali. To dissolve the morphine use this neutral distilled water with the addition of the requisite quantity—say 10 cc.—if decinormal hydrochloric acid, very accurately measured. For alkali, use half strength lime water, i. e., lime water diluted with an equal volume of distilled water (which need not be strictly neutral), and filtered if necessary. Ascertain the exact strength of this solution by titrating with it 10 cc. of the volumetric acid, diluted with some of the neutral water previously prepared. If it requires 46.5 cc. of the diluted lime water, then  $46.5 \div 10 = 4.65$  cc. of the alkali correspond with 1 cc. of decinormal acid. If the titration of the excess of acid after solution of the morphine, has consumed 38.45 cc. of the diluted lime water, deduct this figure from 46.5 and divide the remainder by 4.65. The quotient (1.73) represents the value in decinormal terms of the excess of acid. Hence, the morphine has required for neutralization  $10.00 - 1.73 = 8.27$  cc. of decinormal acid, of which each cc. represents 30.3 milligrams of morphine, and  $8.27 \times 30.3 = 250.581$  mg. is the quantity of morphine indicated by the titration.

If an aqueous solution (from any form of opium, or from a galenical preparation of that drug) is to be assayed by the lime method, it is to be brought to such a concentration that 30 cc. of it will represent 4 grammes of opium, 2 grammes of dry slaked lime are to be added, the mixture allowed to stand with occasional shaking 20 minutes, filtered and 15 cc. of the filtrate taken for the assay, to be conducted exactly as above described. In case the opium preparation contains alcohol, this must be driven off by evaporation on the water-bath. The official tincture may advantageously be diluted with twice its volume of water, the mixture, after standing 20 or 30 minutes, filtered and an aliquot part of the

filtrate, representing 4 grammes of opium evaporated to a volume of 30 cc. Otherwise 40 cc. of the tincture, after addition of about 20 cc. of water, may be evaporated until alcohol is dispelled, the concentrated solution transferred to a cylindrical graduate, the container rinsed with successive small portions of water to bring the volume of the fluid to exactly 30 cc.

Experiments should be made to ascertain whether at a low temperature (15° C. or below) crystallization of morphine in the final operation is practically complete in six hours, or in four hours even, provided the mixture is shaken continuously during 10 minutes, or at frequent intervals during 30 minutes after the ammonium chloride is added. (Note that the quantity of the latter salt must not exceed 0.5 gm.; 0.3 gm. should be sufficient.)

Just how the assay would be affected by the accidental presence of a notable quantity of sugar, is an interesting query. Of course, it would increase the amount of lime taken into solution and would therefore, call for a larger quantity of ammonium chloride, which again might cause a larger proportion of morphine to be held in solution.

Advocates of the Squibb assay method argue that that process should be preferred to the lime method for the following reasons: (1) The yield of morphine is greater; (2) the process is not complicated by the use of an aliquot part; (3) crystallization of the morphine is from a more concentrated solution, and hence should be more complete; (4) no arbitrary correction of the result is required; (5) the morphine is obtained in bold crystals, which, by titration, are shown to be free from any considerable impurity; (6) the assay is free from the sources of possible error to which the lime assay is subject—particularly,

Advocates of the Squibb assay method argue that that process should be maceration in the initial steps.

In rejoinder, advocates of the lime process say:

(1) Deficiency in morphine yield is not unavoidable in a lime assay. It has resulted chiefly from remedial defects in the details of the lime assay as generally practiced. Two main causes have been the use of alcohol, as well as ether, to facilitate crystallization and the prescribing of too large a quantity of ammonium chloride. Besides this, due attention has not been given to the temperature during crystallization and to the amount and method of shaking prescribed. It is well known that in the Squibb method, emphasis is laid on vigorous and prolonged shaking, and results are greatly influenced by neglect of this detail.

I am sure that the same opium solution assayed by the lime method, as hereinbefore described, yields practically the same quantity of morphine as by the Squibb assay. I am not equally positive that the lime method applied to opium in powder will give results correspondingly close to those of the Squibb assay, although it is my belief that they will. If so, the great saving of time and labor demand giving preference to the lime assay.

(2) The aliquot part, which is freely used in other assays, does not condemn an assay process. I have shown that for practical purposes, the aliquot of the Stevens assay (if calcium hydrate is used in place of calcium oxide) may be accepted as reasonably exact. If greater accuracy is wanted, it is easy to weigh the fluids instead of measuring them.

(3) It is apparently true that crystallization in the lime assay is from a more dilute solution than in the Squibb assay, but the conditions for crystallization are more favorable after all, in the former case. It is to be remembered, too, that the crystallization takes place in either case rather from the ethereal than from the aqueous solution. Experiments have shown that residual morphine, under proper conditions, is likely to be less in the former case than in the latter.

(4) If the last statement is true, an arbitrary factor is as necessary in one assay as in the other, the difference in amount being likely to be in favor of the lime process, and compensated at that by a negative correction in the Squibb assay for impurities in the crystals of morphine.

For practical purposes, the small correction may be ignored as immaterial, provided one or the other of the methods in their most approved form be taken as a basis for the commercial valuation of the drug.

(5) Where determination of the morphine is to be made by titration rather than by weighing, the smaller crystals are preferable, as being more quickly dissolved.

(6) The sources of possible error in the lime assay have already been shown to be inconsiderable and largely avoidable by slight modifications in the detail of the assay process. Loss of water by evaporation need not occur to any appreciable extent if obvious precautions are taken.

Confessedly neither of the assay processes under discussion are capable of yielding results of a high degree of exactness. The problem of singling out one from a number of alkaloids which exist in combination with a complex mixture of organic substances, and separating this in a reasonable state of purity by a simple and easily executed process is a baffling one indeed. The lime assay gives the neatest solution we are likely to reach.

Otherwise we may remove, by suitable solvents, the other alkaloids and then by some other solvent to take out the morphine in a state of purity. More than one process involving this principle has been devised—notably the Gordin-Prescott method, in which the solvents employed are successively benzole and acetone, and several shaking-out methods that have been strongly recommended in recent years, in which by-alkaloids are removed from a lime solution by shaking with chloroform, the morphine being afterwards set free by addition of ammonium chloride and separated by shaking out with alcohol, chloroform or some other solvent.

Presumably the results obtained are more nearly exact than those by the process now official, but until they have been put to the test of actual use under varying conditions, it is best to use them only tentatively and as confirmation of results more easily reached by the more familiar process.

#### DISCUSSION.

HARRY M. GORDIN, of Chicago:—There are two difficulties in the lime method. One is that the final liquid is so deeply colored that the end-point in titration cannot be clearly observed. This, however, can be eliminated by a method which I shall publish in the near future.

The second difficulty consists in that the vacuum distillation usually is accompanied by such violent bumping that some of the liquid may be lost by being thrown out of the distilling flask. How did you avoid this difficulty, Dr. Engelhardt?

DR. ENGELHARDT:—As I pointed out already this latter difficulty can easily be overcome

by first distilling the chloroform under ordinary pressure and then distilling the isobutyl-alcohol under diminished pressure. While doing so bumping will never occur.

MR. CHARLES E. CASPARI:—With reference to these methods for the isolation of morphine from opium. The lime method does not yield all the morphine which is present in the opium. While it may be all right for comparative purposes, it does not give absolute knowledge of the actual amount of morphine which is present, either in opium, or opium preparations, which ever may be under examination.

I have had some experience with the method of shaking out with chloroform and alcohol, a modification of Dr. Engelhardt's method, as presented here, and I have found it to yield immediate and certain results, and I have been very much pleased with it. I have used it particularly on tablets,—morphine mixed with other ingredients—and found that it was very satisfactory.

From my knowledge of the methods, I would say that I like the shaking-out method best. It is the simplest, and quickest, and as far as I can determine, the most accurate.

---

## MICROSCOPY OF CINCHONA BARKS AND ADULTERANTS.

---

C. W. BALLARD, M. A., PH. C., PHAR. D.

---

The question of the identity, both macroscopic and microscopic of the various species and varieties of cinchona, has been one of great importance for many years. The difficulties in the way of proper identification, are increased greatly, by the necessary admission of many hybrids of the official species. Of course, the drug is to great extent sold upon assay, but this does not relieve the pharmacognosist of the task of deciding, whether a sample submitted, is official or recognized, as there is always the possibility of the addition of non-official barks to a lot of genuine, and the more likely is such addition, when the drug is in powdered form. The chemistry of cinchona has been treated at great length in the proceedings of this Association, and, likewise, several papers have been submitted upon the macroscopic or gross appearance and structure of the drug, but, in a search of the publications, I fail to find much reference to the microscopy.

The results, in many cases, are not quite as definite and satisfactory as I would desire, and this lack of absolute uniformity, is undoubtedly due to hybridization in cultivation. An excellent article upon the subject of cinchona is given by Vogl, in his text book on Pharmacognosy (German), but this is not accessible to all, as I do not know of an English translation of the work. For this reason, I append a useful classification of the histological characteristics of the various cinchonas taken from this text book. (Dr. A. Vogl, "*Pharmacognosie*," Carl Gerold's Sohn, Vienna, 1892.)

Macroscopic characteristics are treated at length by so many authorities that no reference will be made to them, excepting, if necessary, to more fully explain microscopic structure. I append a list of the literature available at the library of Columbia University College of Pharmacy upon the subject. A further list, and one which is complete up to the date of publication, is given in the English translation of Fluckiger's "Cinchona Barks," by F. B. Power (Blakiston, 1884). In this connection, I would make special mention of a folio volume in French, "*Historie Naturelle des Quinquinas*," M. H. A. Weddell, 1849, which contains excellent illustrations in natural color of many specimens.

CINCHONA CALISAYA AND CINCHONA LEDGERIANA:—As these two species are found to comply with the official requirements as regards alkaloidal content, we may for purposes of comparison consider them as standard. For descriptions and illustrations of histological structure, we cannot do better than consult the material given under the head of Cinchona in the following references: Vogl, "*Pharmacognosie*"; Vogl, "*Atlas zur Pharmacognosie*"; Moeller, "*Pharmacognostischer Atlas*."

As will be ascertained by the above references, the histological elements found in powdered Calisaya or Ledgeriana barks are: cork, flat, thin-walled, with brown contents; parenchyma, thin-walled, containing starch and crypto-crystals; characteristic bast fibers; medullary ray tissue; thin-walled tissue of laticiferous ducts; tissues of the lichens attached to the bark.

Cross sections of barks of both these species, exhibit the following picture. An outer corky layer, brown in color, composed of flat quadrangular cells, the outer portions being very thick, and not being as distinct to view as the inner part. Below the cork is the parenchyma of the middle bark containing numerous bast fibers either isolated from one another or in groups of two to five. In this parenchyma will be found cells containing crypto-crystals and a few containing small starch grains. The laticiferous ducts in this region are circular, thin-walled, and rather larger than the parenchyma cells. Coming to the inner bark, we notice the medullary rays made up of flat rectangular cells with long axis toward the cork, these being usually one to three cells in width. Between them are located the bast fibers, for the most part in groups of four or more. The parenchyma of this region, is composed of small cells, a few of which contain starch. By some authorities, stone cells are said to occur in the middle portion of these barks, but they were not found in the specimens examined.

Cinchona Ledgeriana possesses a larger quantity of bast fibers than Calisaya. The bark parenchyma also contains starch of moderate size, whereas calisaya parenchyma contains very little starch, and that which is present is very small. In many of the bast fibers of Ledgeriana, the ends are double pointed, whereas all other species have single pointed ends.

The indentations or pores of the inner wall of the bast fibers of Calisaya and Ledgeriana are somewhat deeper than those of Succirubra, but are not as broad. The cavities of the fibers in Calisaya and Succirubra are about the same size, but those of Ledgeriana are generally much larger. The bast fibers of all three, are striated in a direction parallel to the length of the fiber, but the striations of Ledgeriana, are fewer and coarser than in the other two. In many instances in Calisaya, the pore begins at the cavity as a single narrow opening, but, upon penetrating the wall of the fiber for a short distance, it separates or branches out into two parts. While there are double pores in Succirubra, the opening from the cavity is very wide, usually wider than the pore itself.

CINCHONA SUCCIRUBRA:—In a cross-section of succirubra bark, we have the outer layer of cork similar to that in the preceding species. The middle bark consists of thin-walled parenchyma cells, containing much starch and many crypto-crystals, and within this parenchyma are laticiferous ducts which are very large. Very few bast fibers are present in this region. In the inner bark are found the medullary rays and bast fibers, the latter usually in groups running parallel o

the rays. The rays are usually three cells in width and are almost parallel to one another.

In the powder, the bast fibers are the most prominent element, being more numerous and rather more slender in this variety than in *Calisaya*. The fibers are striated, but the striations are coarser than *Calisaya*. Three types of fiber were noted: those with both ends sharp-pointed; those with one end square and the other pointed; the third with one end square, the other being square excepting for a projecting point, similar to the peculiar fibers of *Ledgeriana* except that those of the latter have a double point. The variety with one narrow projecting point predominate. The indentations of the inner wall, are wider but not as deep

COMPARISON OF TYPICAL FIBERS.

1. *Cinchona calisaya*.
3. *Cinchona succirubra*.
5. *Cuprea* Bark.

2. *Cinchona ledgeriana*.
4. *Cinchona officinalis*.
6. *Maracatho* Bark.

as those of *Calisaya* and *Ledgeriana*. There are, in many fibers, double pores which have wide openings from the cavity, thus distinguishing them from *Calisaya*.

One fact noted, was that the parenchyma of this variety, is for the most part filled with starch; also the total amount of starch in the field is considerably greater than in *Calisaya* or *Ledgeriana*. This feature, although not an altogether certain and definite one, may furnish a clue to the derivation of a sample.

One other element which may be found in this variety and which may be rather confusing at times is lichen tissue.

*CINCHONA OFFICINALIS (Lora Bark)*.—The transverse sections of specimens of this variety exhibit an outer corky layer, to which lichens may be adherent.

The cork cells are of the usual type, rectangular, small, thin-walled and brown. Below the cork is the parenchyma of the middle bark containing a few small laticiferous ducts. Bast fibers, if present in this region, are very few in number. In the inner bark, occur the medullary rays composed of large rectangular cells, each ray running parallel with the others and being somewhat wider as they approach the middle bark. These rays are two cells wide in the inner bark, but expand to three or four cells in width, upon reaching the middle region of the specimen. Between the rays occur bast fibers, singly or in groups of two to four, and have very small cavities. The remaining space between the rays, is filled in with the bark parenchyma interspersed with the sieve cells.

The powder of *C. officinalis* contains the usual elements found in the true cinchonas. The fibers and parenchyma are of about equal prominence. The structure of the cork cells is easily seen, but the fibers are not as numerous as in the other official varieties. In a majority of cases, they are flattened at one end and sharp pointed at the other, although a few are pointed at both ends. The cavity is very narrow and the indentations or border pores, which are in all cases single, extend to the outer margin of the fiber. Striations are found running parallel to the long axis of the fiber. The parenchyma in the powder, is usually in very good condition and is always more or less filled with small starch grains and small crypto-crystals. Medullary rays are large and easily seen in the powder, the individual cells being rectangular and occurring in groups attached to the fibers.

**CUPREA BARK (*Remijia pedunculata*):**—This substitute for the genuine cinchonas, is not entirely worthless, although of an entirely different genus. It contains some cinchona alkaloids, and is therefore more likely to escape detection during assay processes.

The cross-section of this bark shows a few layers of thick-walled brown cork cells at the outer margin. The middle bark contains groups of characteristic, yellow, stone cells, large and moderately thin-walled, usually filled with starch or reddish-brown contents. Laticiferous ducts are said to occur in some specimens, but I did not observe them in two out of three specimens examined. The inner bark contains the medullary rays and groups of densely-packed, small, but thin-walled bast fibers. The rays are very irregular as regards direction and width. In many cases they are wavy and not parallel with each other or extending through the bark at right angles to the cork, as in genuine barks. The individual cells of the rays are rather long, and either rectangular or circular, being filled with reddish contents, making them much darker than the surrounding cells. In many specimens, the rays broaden out upon reaching the middle bark, as in *C. officinalis* and merge almost imperceptibly with the parenchyma of this region. In width, the rays vary from one to four cells. The bark parenchyma and sieve-tissue of the inner bark, is almost entirely displaced by the densely-packed bast fibers.

The powder of this variety, is characterized by numerous stone cells and bast fibers, square or rounded at the ends, and occurring in groups arranged end to end. Their walls are very thin and the cavities of these fibers are large, but the inner walls are not, markedly, indented as in genuine species. The stone cells

MARACAJIBO BARK.

| 4. Longitudinal view of parenchyma. |                                   |

are square, or polygonal, with a few circular shape, finely striated with deeply-indented inner margin. Some are filled with starch, others with reddish-brown contents. The medullary ray tissue, is very prominent in the powder both in longitudinal and transverse section. It is adherent to the short fibers and the bark parenchyma. Many of the parenchyma cells are filled with starch. Crypto-crystals are present in this powder, but are less numerous and smaller than in the genuine barks.

The peculiar fibers render this adulterant very easy of detection, and the stone cells render such finding certain.

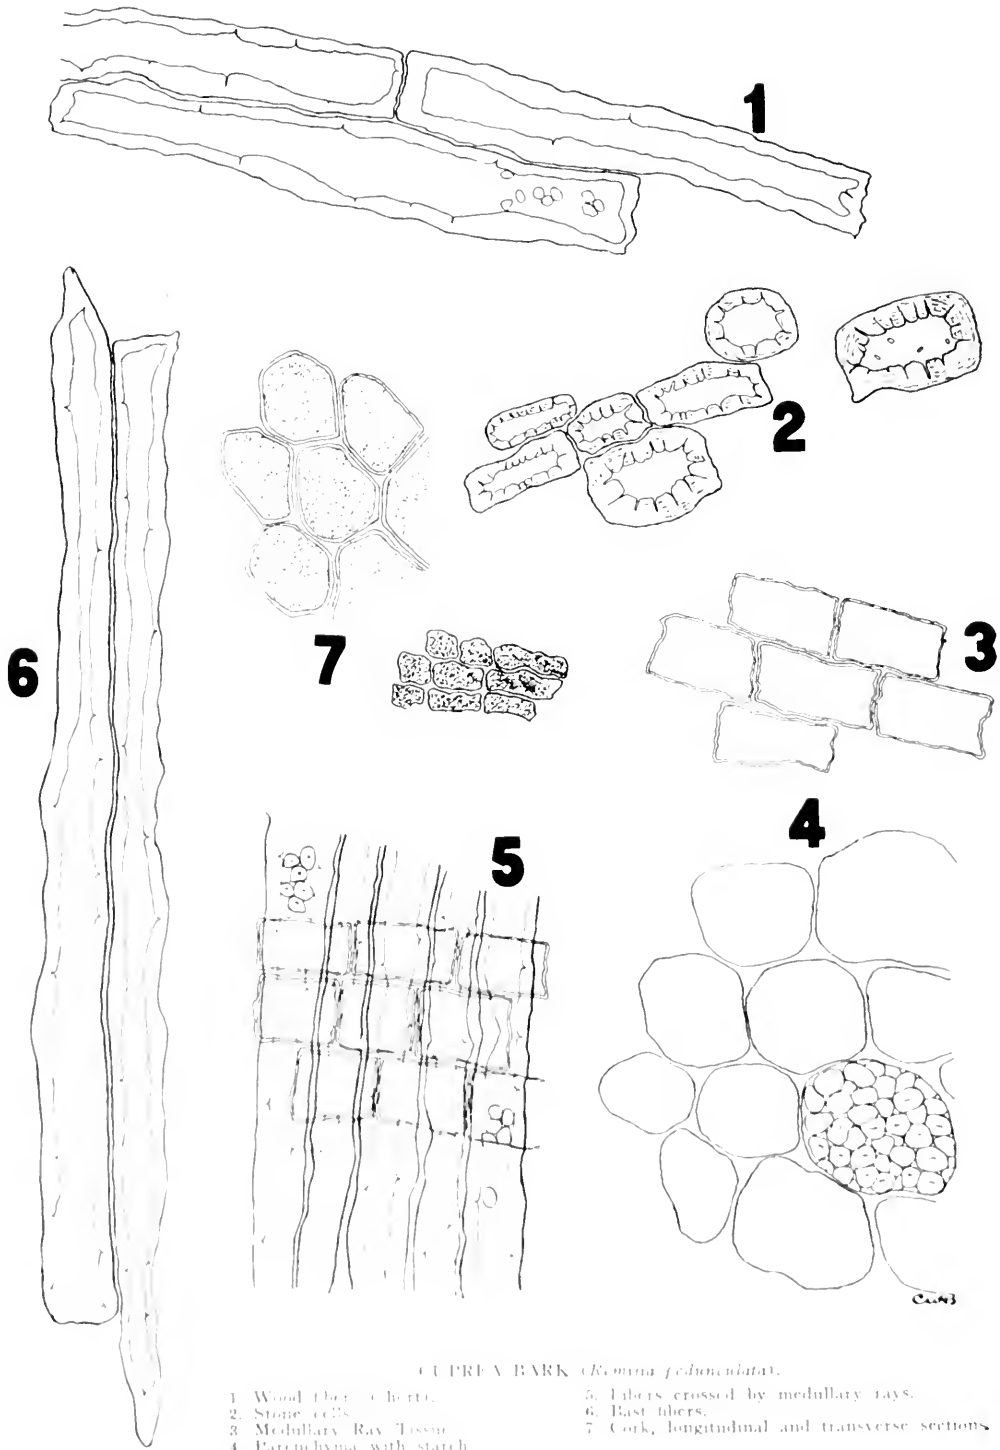

MARACAIBO BARK:—Maracaibo bark has been used very recently as an adulterant of the yellow cinchonas, especially that sent to market in chip form. It is not, in any sense, a purely theoretical adulterant, or one which might be thought to be of use for nefarious practice, for several samples of cinchona have consisted in part, and in some cases the greater part, of this spurious bark. Its botanical origin seems to be rather obscure, and it is not mentioned under the above commercial name in most scientific works.

The transverse section of most samples, shows very little corky tissue, as this peels away very easily. The middle region of the bark, contains many groups of large thick-walled yellow fibers and few yellow stone cells. Laticiferous ducts are also present. The parenchyma is of small irregular brown thin-walled cells. The inner bark consists of very small, and dark-colored medullary rays, usually two cells in width; the rows being comparatively far apart as compared with all other barks. Between the rays, we find groups of large, yellow bast fibers and rather large quantities of small, irregular thin-walled parenchyma. The fibers are wider than any other related bark, but are not as numerous as in *cuprea*.

In powdered form, the bast fibers are, as in the true cinchonas, most prominent. They are considerably wider than fibers of the true species, and are very coarsely marked with striations running parallel to the outer margin. Both ends of the fibers are sharp-pointed. The cavity is very large, and the indentations extend almost completely to the outer margin of the fiber. The wood fibers which are present, are about as long as the bast, but are very slender, thin-walled, with square ends and filled with reddish-brown contents. The stone cells are large, triangular or rectangular in shape, yellow in color, with thick walls. The cavities of these stone cells are marked by many indentations or pores and they may be filled with starch. Numerous well defined crypto-crystals are present, many of them being very large.

RENEWED BARK:—A transverse section was prepared from a sample of the so-called renewed bark, and examined to discover any changes brought about by the renewing-process. This renewing, or stripping, of the outer bark from the tree, and the covering of the bared places, with moss or material to prevent access of light, is said to yield a bark much higher in alkaloid than the ordinary.

In renewed bark, the thick, brown, corky layer is of course absent, although a small amount may remain. In the region which, in an untreated bark, would correspond to the middle bark, we find at the outer edge several rows of flat, almost perfectly rectangular cells, resembling cork but not deeply-colored; they representing secondary cork formation. Below this secondary cork, is a wide

zone of circular parenchyma cells, in which remains of the previously existing medullary rays may sometimes be seen. A few small laticiferous ducts are also present in this region, but bast fibers are entirely wanting. In the region corresponding to the inner bark, are the true medullary rays, two or three cells in width, and of large but narrow cells. The bast fibers in this region, are very numerous with thick walls, small cavity, and, in a majority of instances, a rectangular outline on transverse section. Small amounts of bark parenchyma and sieve tissue also occur between the rays.

In the powder of renewed bark, the most prominent elements are the fibers and the masses of secondary cork.

## SUMMARY OF THE IMPORTANT CINCHONA BARKS ACCORDING TO HISTOLOGICAL CHARACTERISTICS.

(After Dr. A. Vogl.)

## A. Barks with cork present.

## I. Bast fibers prominent—radially and tangentially arranged.

## a. Stone cells present in middle bark and outer portions of inner bark.

Stone cells mostly in middle bark—laticiferous ducts absent.

Wood cells (*stabzellen*) in bast region=*C. lancifolia*.

Wood cells (*stabzellen*) none=*C. lucumacfolia*.

Stone cells not prominent in middle bark.

Bast bundles in very perfect isolated groups=*C. macrocaly*.

Bast bundles toward the last not arranged in series=*C. Palton*.

## b. Stone cells absent or scattered in middle bark or outer portion of inner bark.

Bast fibers very thick (90-250 mm.)—Laticiferous ducts wanting or at best very narrow.

Wood cells present=*C. Pahudiana*.

Wood cells absent=*C. pubescens*.

Bast fibers moderately thick=*C. obtusifolia*.

Bast fibers thin—laticiferous ducts wanting or narrow=*C. officinalis*.

## II. Bast fibers arranged in radial series or rows.

## a. Laticiferous ducts absent.

Bast fibers thin or equally thick throughout the section—in interrupted radial rows=*C. Pitayensis*.

Bast fibers unequally thick—the outer ones thinnest.

Medullary rays of large cells—wood cells present.

Middle bark without stone cells or with single stone cells=

*C. cordifolia*.

Middle bark with many stone cells=*C. Lancifolia*.

Medullary rays of small cells—as a rule no wood cells=*C. lancifolia*

## b. Laticiferous ducts present.

Middle bark containing numerous stone cells.

Bast fibers thin or very thin.

partly in interrupted rays—wood fibers present=*C. scrobiculata*.

In interrupted rays—wood fibers absent=*C. ovata*.

Bast fibers moderately thick—wide laticiferous ducts in middle bark—very many stone cells—wood cells in bast region=*C. peruviana*.

Middle bark containing scattered stone cells or the latter absent.

Narrow laticiferous ducts.

Bast fibers moderately thick, the outer ones thinner.

In regular zones—bast region soft=*C. officinalis*.

Without regular zones=*C. heterophylla*.

Bast fibers thick the outer ones thicker=*C. ticujensis*.

Wide laticiferous ducts.

Bast fibers very thin in interrupted radial series.

With "KOH," sections give blood-red reaction—bast fibers orange color=*C. succirubra*.

With "KOH," thin sections give yellow or reddish-brown reaction—fibers yellow=*C. cal.* or *ledger*.

B. Barks in which cork is absent.

a. Bast fibers in tangential bundles—moderately thick, bark very soft, brittle and fibrous=*C. lucumacifolia*.

b. Bast fibers expanding in outward direction—many in radial series thin or very thin—for the largest part in uninterrupted lines.

In double lines—cork still present—wide laticiferous ducts and numerous stone cells, fracture rough showing protruding ends of fibers=*C. scrobiculata*.

In single lines—stone cells wanting—short fracture=*C. australis*.

Moderately thick in interrupted single lines.

Bast fibers equally thickened—medullary rays extending directly outward—sharp fracture=*C. calisaya*.

Bast fibers not equally thickened.

Large celled medullary rays=*C. officinalis*.

Small celled medullary rays=*C. micrantha*.

## ASSAY OF HYDRASTIS AND FLUIDEXTRACT OF HYDRASTIS.

H. W. JONES.

The abstracts of proposed changes to be made in the forthcoming revision of the U. S. P. have been greeted with great interest and none perhaps more so than those dealing with the alkaloidal assays. (Jour. A. Ph. A., 1914-7, pp. 984-997.) Among the various assay processes of the U. S. P. (VIII), there was assuredly none more in need of revision than that of Fluidextract of Hydrastis, and the proposed change in the assay of this preparation will no doubt meet with general approval.

Puckner (Pharm. Rev., 1908, 26, pp. 132-137) called attention to the considerable error incident to the use of the eighth revision method, and pointed out the source of error, namely, the carrying down of hydrastine by the berberine hydriodide precipitate with the result that the 50 cc. aliquot part taken did not fully represent 5 cc. of the fluidextract, but gave too low a result. He proposed an excellent modification of the method, although apparently this modification has not met with general approval.

Eldred and Pence (Proc. A. Ph. A., 1908, pp. 836-838) also remarked on the low results obtained through the use of the eighth revision method, and also gave results obtained by a method used in their practice.

Dichgans, working under Prof. Tschirch, in a comparative examination of the assay processes of the different Pharmacopœias (*Apoth. Ztg.*, 29, 46, pp. 516-519),

has also discovered the fault in the method, and through comparison with the methods in use in other countries, has shown the low results obtained by its use.

While there is no doubt that most manufacturers have abided by the eighth revision method in standardizing Fluidextract of Hydrastis, it is evident that this has led to grave errors, for when this preparation was standardized to 2% hydrastine by the eighth revision method, the preparations were in fact some 15% to 20% above this figure. This also worked an injustice on the manufacturer who, instead of being able to obtain a full yield of fluidextract from a given amount of this high-priced drug, was able to gain only 80% to 85% of his possible yield.

The following results were obtained in this laboratory on different samples of Fluidextract Hydrastis and will suffice to bring out the points I wish to make. Preparations 1 and 2 were made in the laboratory strictly according to the U. S. P. (VIII) process for Fluidextract Hydrastis. Preparation 3 was also prepared in the laboratory but contained 20% glycerin instead of the official 10%. Preparation 4 was the product of a well-known manufacturer and was purchased in the open market.

Preparation	Drug assayed by U. S. P. VIII	Fluid extract by U. S. P. VIII	Fluid extract by U. S. P. IX
1	4.15	3.52	4.22 4.2
2	3.12	2.56	3.14
3	3.83	2.61	3.21 3.26
4	....	2.0	2.26

It will be observed that in preparations No. 1 and 2, the assay of the fluidextract by the ninth revision method is slightly higher than that of the drug from which it was made. In preparation No. 3, this peculiarity does not occur, and this is no doubt due to the fact that a 20% glycerin menstruum does not extract the drug as completely as does a 10% glycerin menstruum. In our opinion the apparently high results obtained by the ninth revision method are not incorrect, but the fault lies in the eighth revision method for the assay of Hydrastis, which unfortunately has been carried on into the ninth revision, that is, the amount of ether used in the maceration of the drug (150 cc. ether to 15 g. Hydrastis) is too small to prevent a crystallization of the hydrastin. This has been remarked upon by Dichgans (*Apoth. Ztg.*, 1914, 45 pp. 498-501) who shows that the results obtained by this method are lower than those obtained by the Swiss Pharmacopœia method, or by the method of Caesar & Loretz (*Jahres-Bericht von Caesar & Loretz*, 1913, pp. 155-156), in both of which methods 6 g. of drug are macerated with 120 g. (168 cc.) of ether, or more than two and one-half times as much ether in proportion as is used in the U. S. P. method. This might not be necessary for drugs low in hydrastin, but as an assay method should be applicable to all grades of the drug.

It might be remarked further, that the high results obtained by the ninth revision method for the fluidextract were at first attributed to the hydrastin being contaminated with glycerin. The hydrastin residues were, however, dried to constant weight and showed no appearance of glycerin. To be assured further, the combined ethereal extractions of the fluidextract were washed with several small portions of water in the hope of removing any glycerin which they might

contain, but the final results were practically identical with those first obtained.

The conclusions to be drawn are then, that the ninth revision method for the assay of Fluidextract of Hydrastis is satisfactory; and that the method for Hydrastis might well be reconsidered, and a larger proportion of ether used to extract the drug.

## WHAT IS THE BEST END-POINT OF THE REACTION IN THE FROG-HEART METHOD OF DIGITALIS ASSAY?

---

L. W. ROWE.

---

While there are various methods in use for standardizing the digitalis series of heart tonics, the frog-heart method devised and introduced by Houghton,<sup>1</sup> in 1894, has perhaps been most widely used in more or less modified form.

These modifications are specifically due to differences of opinion, as to the proper length of time, after dosing, to note the end-point of the reaction, namely, the characteristic systolic stand-still of the heart or the death of the animal with its heart in systole.

The original method made use of the minimal lethal dose, or smallest dose capable of causing the death with heart in systole, of a majority of the frogs to which a certain amount of the preparation in question had been administered. In a somewhat amplified form<sup>2</sup> the method was presented before this Society in 1909.

In 1902, Famulener & Lyons<sup>3</sup> described a method which has been in use in the University of Michigan Pharmacology Department for some time, according to Edmunds.<sup>4</sup> This consists, in brief, in administering such a dose of a digitalis heart- tonic to a frog, as to cause paralysis of the heart in systole in one hour. Edmund's modification differs only in having complete stoppage of the heart—not only systolic but auricular as well.

Barger and Shaw<sup>5</sup> used the same method of injection, namely, into the dorsal lymph sac, but the frogs were kept under observation until the heart stopped, which they found was within three hours, if at all.

Fraenkel<sup>6</sup> practically limited the time to one hour, although a range from thirty-five to one hundred minutes is allowable, in his modification.

Ziegenbein<sup>7</sup> used the modification originated by Hans and Arthur Meyer of fastening male frogs to a board and exposing the heart before injection. The solution is injected into the thigh lymph-sac and in such a quantity as to produce systolic standstill in two hours.

Gottlieb<sup>8</sup> used as his unit "The smallest amount of the solution which will call forth systolic standstill of the heart of a 30 gm. frog in exactly thirty minutes."

Focke first published his modification of the frog-heart method in 1902.<sup>9</sup> This has been changed somewhat, but is essentially to determine the minimum dose causing systolic standstill in seven to fifteen minutes.

His method is more complicated than the others because of his taking into account the time period. The value of a sample is the result obtained by dividing

the frog weight by the product of the dose multiplied by the time. This makes the element of time a very important factor. Delayed absorption or exceptional resistance will lower the apparent value greatly.

While at this time, we are not considering suggested methods for standardizing the heart tonics of the digitalis series, other than by the use of frogs, it is not inappropriate to refer to the use of the warm-blooded animals. For example, Hatcher's Cat Method,<sup>10</sup> Reed and Vanderkleed's Guinea Pig Method,<sup>11</sup> Heinz' Mouse Method,<sup>12</sup> and the use of rabbits or dogs to determine the blood pressure and heart action, are all valuable. But for obtaining a fairly accurate estimation of the relative values of two preparations they do not appear to offer any material advantage over the frog-heart method first suggested and used for this purpose. Not only this, but cost, convenience and lack of general adaptability have prevented any extended application of them.

Edmunds & Hale<sup>13</sup> concluded that because in most cases the toxic action is not on the heart but on the respiratory centres "Methods which employ as a standard the minimum lethal dose obtained from the higher animals are not applicable to the physiological assay of the digitalis series."

The Frog-Heart Method may be considered to have three distinct modifications or that there are two modifications of the original twelve-hour method of Houghton, namely, the so-called Short-Time Method of Focke, and the One-Hour Method of Famulener & Lyons.

The Twelve-Hour Method of Houghton, is, distinctly, one allowing the total toxic effect of the drug to take place. The animal dies or recovers. A more or less total paralysis of the whole heart or of the ventricles may have taken place in many of the test animals, but unless this occurred and resulted in the death of a majority of five or more frogs following the injection of a certain quantity of the drug, a larger quantity must be chosen as the minimal dose. Delayed absorption, therefore, due to the nature of the drug will not vitiate the results: even digitalis has every opportunity to exert its characteristic effect.

During a large part of the year this takes place in three or four hours, or even less, in the case of *Strophanthus*, but during the winter months, and especially if the water in which they are kept is very cold the final result may be delayed considerably more than twelve hours.

If, however, we limit the time to one hour, or to ten minutes, and expect the drug to show its whole range of action, from therapeutic through to toxic, it is probably demanding the impossible of such a complex mixture as a fluidextract of digitalis. Absorption could not be complete in ten minutes and possibly not in one hour.

If the sample were a pure principle to be tested in comparison with a standard of like properties, the results should be comparable, otherwise the uncertainties of a physiological assay are considerably increased. Edmunds & Hale<sup>13</sup> conclude "that between these two methods (the twelve-hour and one-hour) it is largely a question of personal preference or convenience as far as can be judged in the light of our present knowledge."

Focke's Short-Time Method gives such inaccurate results, is so complicated, and is open to such extreme variations, that no results, by this method, are included.

The following series of tests has been carried out to compare more directly the advantages of two of the frog-heart methods of digitalis assay previously mentioned. The minimum dose of each preparation was determined according to both methods under as nearly similar conditions as possible. By personal observation as to the definiteness of the end-point, we were able to form an opinion regarding the value of each method as a means of determining the activity of preparations of the digitalis series:

The fact which stands out most prominently from a superficial examination of this date is that the minimum dose of digitalis preparations is in most cases less by the one-hour method than it is by the twelve-hour method. The opposite is true in the case of Strophanthus preparations. This seems more logical since one would naturally expect it to require more of the active substance to cause systolic stoppage of the heart in one hour than to cause the death of the frog. Digitalis in sub-lethal doses must, therefore, produce an early paralysis of the heart from which the frog recovers. This fact in itself would seem to point to a possible cause for discrepancies in the one-hour method.

It is only with samples of Tincture Digitalis that we are able to obtain a clearly defined and uniform end-point by the one-hour method. In most of the tests of other members of the digitalis series the end-point is either difficult to determine because of inability to check the minimal dose or the heart does not stop in definite systole. It would seem that there should be some very nearly constant ratio between the minimum dose obtained by each method with the same preparation, but as stated above this has not been found true except approximately in the case of Tincture Digitalis.

Our observations would lead to the conclusion that the variability in the individual resistance of the frogs to digitalis plays a more important part in the one-hour method of assay than it does in the twelve-hour method and consequently adds to the indefiniteness and inaccuracy of results by the latter method. The

time element also has an important bearing on the comparative results by the two methods. Where the time which elapses between the injection of the active material and the observation of the result is relatively short the effect of the same dose of the same preparation (and by the same does we mean in proportion to weight) upon frogs of different resistance may be sufficient to produce conflicting results. On the other hand in a method involving longer period of observation where the death of the animal rather than a paralysis of the heart is the final end-point this difference of resistance does not play so important a part. It is true that even in the twelve-hour method the variation in the resistance of the test animals is an important factor, but it can be more easily and completely eliminated by this method than could be done in the case in the one-hour method, even if a similar procedure were applied, i. e., elimination of the factor of resistance variation by the use of a large number of test animals, and of a standard for comparison.

The point that we wish to emphasize, however, is that while variation in resistance can apparently be offset in both methods by the carrying along of a standard preparation of known strength, yet there seems to be varying degrees of paralysis of the heart; and that this paralysis has no uniform relationship to the death of the test animal. In the data on F. E. Digitalis in some cases, the minimum dose was the same by both methods, but the average lethal dose exceeded the one-hour dose by 22%, with a maximum variation of 81%. In the case of the Tincture Digitalis the variation ranges from 10% to 60%, the average excess required to kill the frogs over that necessary to cause systolic stand-still being 33%. Comparison of Strophanthus tinctures by the two methods shows that 54% of the one-hour dose will kill the frog, Squill 80%, Convallaria 108%.

From our observations we, therefore, summarize as follows: First, that the end-point in the one-hour method is more indefinite and consequently more difficult to determine than that of the twelve-hour method; second, that the variation in resistance of the test animal is a source of much greater error in the accuracy of the shorter method than it is in the other; third, that an absolute end-point such as death is more satisfactory than one which may show so many degrees of variability.

Our conclusion is that the death of the frog with heart in systole is a more accurate and dependable end-point in the reaction than a similar stoppage of the heart observed at any time previous to the absolute death of the animal.

## Contributed and Selected

### THE ARMY HOSPITAL CORPS.

WM. B. DAY, PH. G.

Surgeon General Gorgas, in his annual report to the Secretary of War, recently published, earnestly urges an improvement in the conditions of the Army Hospital Corps. He again calls attention to the difficulty in securing desirable men for this important corps, and points out the fact that other branches of the service offer superior inducements. Dr. Gorgas refers to bills that have been introduced in Congress looking to the improvement of the efficiency of the Hospital Corps and which were drafted in accord with the recommendations of his office,—evidently meaning the Hughes-Bacon bills. But these “have not received the approval of the War Department.” And this is the gist of the difficulty which our committee met with in urging the passage of these bills—their failure to secure the approval of the War Department,—which blocked our efforts completely. We were informed that the War Department had under consideration remedial legislation for the Hospital Corps. Secretary Garrison informed President Beringer that “should conditions in the Hospital Corps ever become so unsatisfactory, and such as to indicate that an improvement can be brought about only by an increase in pay of the members, the necessary increase will be recommended.” Judging from the following paragraphs, quoted from the Surgeon-General’s report, this time has arrived:—

“Attention has been repeatedly called to the deficiency in the number of Hospital Corps authorized for service, and recommendation made for an increase. On April 29, 1914, the Secretary of War authorized an addition of 1,500 men, making a total of 5,012 for the corps. May 9, 1914, authority was granted for the appointment of sixty additional sergeants. To date, 543 men in excess of the number previously allowed (3,512), have been re-enlisted in, enlisted for, or transferred from the line, to the Hospital Corps. The greater number of these men were used in the organization of new mobile units and field vacancies in the Second Division and with organizations on duty on the Mexican border.

“The class of men secured for the Hospital Corps, have by no means been satisfactory. During the excitement attending a possibility of active service in a campaign beyond the limits of the United States, a greater proportion of desirable men presented themselves for enlistment, and the commanding officer of one of the new organizations reported that he was receiving better men than had been serving with the detachment at his post. With passage of the incentive, the quality again deteriorated. A commanding officer of a post in commenting on his detachment expressed himself as follows: ‘The sergeant is efficient and energetic, but the Hospital Corps men, with the exception of the sergeant, are

the riff-raff of the Army—and I am not putting it too strongly. In two or three cases they are not only woefully inefficient but are not clean personally. I have directed the surgeon to make a special report in the case and will give him any help he needs from our own troops. I really think that these men were transferred to rid some other command of worthless men, an almost criminal procedure when one considers how badly good Hospital Corps men are needed.'

"In each annual report of the Surgeon General for the past two or three years, attention has been invited to the inferior character of a considerable proportion of the men who are accepted for the Hospital Corps. And the reason for this has been pointed out, viz., the inferior inducements offered by the Hospital Corps in comparison with the opportunities offered by other branches of the service. Bills have been introduced in Congress for improvement in this respect along the lines recommended by this office, but these have not received the approval of the War Department. It is earnestly recommended either that this disapproval be reconsidered or else that other inducements be made by means of special ratings or in any other way whereby service in the Hospital Corps can be made sufficiently attractive to secure a desirable class of men."

The Surgeon General presents the bright as well as the dark side of the picture, as shown by the following instances of heroism displayed by members of what is sometimes termed a "non-combatant branch" of the Army:—

"Fortunately, however, all the men secured, even under the present unfavorable condition, are not undesirable men and a number of individual cases have occurred during the year where enlisted men of the Hospital Corps have rendered efficient and distinguished service. In October, 1913, a train carrying a band and two companies of Coast Artillery Corps, left the track and crashed through a wooden bridge near Buckatunna, Miss., and as a result, seventeen men were killed and nearly one hundred more or less seriously injured. Sergt. Halbert M. Beasley, Hospital Corps, although he was himself injured, worked unceasingly in rendering first aid and assisting in the removal of the wounded. For this he was awarded a certificate of merit. On March 25, 1914, Pvt. First Class Thomas Mosely, Hospital Corps, was awarded a certificate of merit for distinguished gallantry in action against hostile Moros while private, Hospital Corps, when he bandaged a wounded officer, in the face of a heavy fire from the Moro trenches, and carried him to a place of safety at the risk of his own life. This at Bagsak Mountain, Jolo, P. I., June 11, 1913."

"On April 21, 1914, Pvt. First Class Edward W. Morrison, Hospital Corps, was awarded a certificate of merit for meritorious conduct in rendering first aid to wounded comrades under fire of hostile Moros at Mamaya Peak, P. I., December 15, 1913."

As showing the need for medical knowledge and skill of no mean order and as an instance of the heavy responsibilities assumed by the military pharmacists is the following:

"On March 6, 1914, a private of the Signal Corps detachment at Nulato, Alaska, presented evidence of an appendiceal abscess. No medical officer was present with this small detachment, but Sergt. First Class Richard A. Wood, Hospital Corps, diagnosed the case and communicated by telegraph with the surgeon at Fort Gibbon, about 250 miles distant. The surgeon started, but the distance had to be traveled by dog team and at least four days would be required for the trip. Two days later Sergt. Wood communicated with the surgeon by telegraph and stated the urgency of the symptoms and the condition of the patient. The condition of the soldier was so urgent as to demand immediate

operative interference and Sergt. Wood was authorized to proceed. On the same day the sergeant opened and drained the abscess under a local anesthesia. When the surgeon arrived the patient was in good condition. The surgeon reports that in his belief Sergt. Wood, by performing a prompt drainage of the abscess, greatly facilitated the patient's recovery and probably saved his life."

The authorized strength of the Hospital Corps is as follows:—

Sergeants, first class.....	300
Sergeants .....	422
Corporals .....	50
Privates, first class, and privates.....	4,240

Total ..... 5,012

There were in the service June 30, 1914:—

Sergeants, first class.....	300
Sergeants .....	399
Corporals .....	41
Acting Cooks .....	180
Privates, first class, and privates.....	3,135

Total ..... 4,055

The new committee on Status of Pharmacists in the Government Service, to be appointed by President Mayo, should lose no time in getting in touch with the War Department with a view to learning at the outset whether the Department will approve of a bill drafted along the lines of the Hughes-Bacon Bill—and if such approval is withheld then a strong effort should be put forth to discover what the objections of the Department really are and how they may be overcome. It is futile to enter upon another campaign at the coming session of Congress until these facts are determined.

## A SYMPOSIUM ON THE PHARMACEUTICAL SYLLABUS.

(Continued from last month.)

BOSTON, MASS.

The Pharmaceutical Syllabus was first considered at a meeting held at Niagara Falls in June, 1906, and plans for its preparation were worked out by a Committee consisting of Willis G. Gregory of Buffalo, Henry H. Rusby of New York City, and Henry L. Taylor of Albany. This Committee soon decided to give the proposed publication a national character, by inviting the National Association of Boards of Pharmacy and the American Conference of Pharmaceutical Faculties each to appoint representatives on the Committee. This invitation was formally accepted by each of the organizations in September, 1906, and the membership was thus increased to five members, who soon afterward appointed sixteen other members from boards of pharmacy and faculties of colleges of pharmacy. The number of members has been twenty-one since 1906, with but few temporary vacancies. In 1910, after the issue of the first edition, the American Pharmaceutical Association adopted a by-law providing for representation on the Committee and the method of appointment of members was changed so that each of the three organizations represented appoint seven of the twenty-one members on the Committee. Since its organization, the Committee has included representatives from many of the leading colleges of pharmacy in the United States and from many of the state boards of pharmacy.

The expenses of the Committee have been paid from annual appropriations of twenty-five dollars from each of the three parent organizations and from the receipts from the sale of the second edition. No member of the Committee has been paid anything for his work, which has been very considerable in several cases.

The need of an outline of the standard course in pharmacy is generally conceded and it was strikingly shown, when the Committee began an inquiry into the courses given by colleges of pharmacy throughout the country, by the differences in subject-matter, length of courses and methods of teaching that were reported. Members of the Committee had great

differences of opinion on what constituted a proper course in pharmacy and many stormy times have resulted from these and other causes.

Dr. Henry L. Taylor, of Albany, N. Y., an official of the New York State Education Department, was secretary-treasurer of the Committee from 1906-1914, and has done more than any other one man for the Syllabus. Dr. Taylor is an educator and not a pharmacist, and his point of view was often very different from that of other members of the Committee. He is a man of tireless energy with the courage of his convictions and he was often at odds with various members. We believe that in the future the great amount of unselfish work done by Dr. Taylor will be appreciated at its true worth. On the issuance of the second edition, Dr. Taylor withdrew from the office of secretary-treasurer, in accordance with notice previously given, and the writer was elected to the office.

The recent agitation against the Syllabus came almost entirely from certain members of the Committee, apparently because they could not induce the Committee to adopt some of their ideas and they were unwilling to accept a compromise. We believe that these gentlemen are sincere in their efforts, but we could not agree to all of their propositions and thus we antagonize them.

No member of the Committee believes that the Syllabus is near to perfection. The first edition was very imperfect in many parts. In the second edition these faults are largely corrected, or replaced by new matter, and this edition is a great improvement over the first. This is the only way in which such a book can be prepared and if succeeding editions each show improvement over the immediately preceding one we shall ultimately have as nearly perfect a work as can be obtained. With this in view, the Committee is planning for revision every five years. The proposal, which has been made and rejected, that all of the good in the present syllabus be thrown away and a new one prepared, was not a good one. What we need is constructive, not destructive criticism.

THEODORE J. BRADLEY.

NEW ORLEANS, LA.

The object of the Syllabus, is uniformity in teaching the various branches of pharmacy and as a guide to both the teachers of schools of pharmacy and the examiners of boards of pharmacy. It must be admitted that graduates of pharmacy are examined by other boards than the one of the school, it is rather the exception than the rule.

If there is no unanimity of action between colleges and boards of pharmacy of the same state, the object of the syllabus is defeated.

Personally, the Syllabus appeals strongly to me and while there is, as has been too often admitted, gross errors in the old issue, it can be made to serve a most excellent purpose in the pharmaceutical education of this country, but, not only is its adoption by every college and board of pharmacy necessary, to carry out the objects of those credited with its introduction, but the boards and colleges of the same state must work along the same lines.

The fact that this work is the result of the combined efforts of members composing every avenue of pharmaceutical endeavor, is in itself an indication of the kind of pharmaceutical thought that it reflects. Composed of committee of seven each, from the American Pharmaceutical Association, the National Associations of Boards of Pharmacy and the American Conference of Pharmaceutical Faculties, it does not seem possible that such a Committee could have issued something wholly at variance with the pharmaceutical educational needs of this country.

The work of the Syllabus Committee proper could be materially strengthened by the appointment of sub-committees of five members each, from the same associations from which the Syllabus Committee was derived, to correct and eliminate any of the short-comings in the publication that may exist. This would not be any additional expense to the Syllabus Committee, as these members could be selected from the membership of the three bodies who regularly attend the annual meeting of the American Pharmaceutical Association.

PHILIP ASHER, M. D., DEAN

BALTIMORE, MARYLAND.

Sir: I am somewhat embarrassed by your request for an expression of my views upon the second issue of the Pharmaceutical Syllabus, since I feel incompetent to discuss a subject which has had such long and careful study and such close attention from an unusually able committee; on no account, would I discuss any part of the Syllabus, excepting that which refers to the branches which I am trying to teach.

Much pleasure and encouragement have followed an examination of the last edition; the changes made bring it more nearly in accord with my ideas regarding the teaching of dispensing and commercial pharmacy. I have, lately, gone over the outline given for these branches and am pleased to note that, during the last twelve years, our efforts have been in close accord with the suggestions of the Syllabus committee. As an instance of the help I derive, I will state, that, for several years I have been wondering if I should continue to instruct students how to spread plasters. I find that the Syllabus recommends that such instruction be given, consequently, I am justified in continuing the practice.

The separation of pharmaceutical jurisprudence from the commercial course is, in my

opinion, entirely proper, and another instance of progress, as this was not so in the former edition of the Syllabus.

In regard to the time devoted to the different branches, I notice that seventy-five hours is suggested for commercial pharmacy. We have given but forty-eight hours to this branch and have found it quite enough to equip the better students for the commercial part of pharmacy. If I could be decided in any criticism of the dispensing course, I would say that the time allotted to this important work is entirely too little. We find that a hundred and ninety-two hours in the two years is none too much to give students the knowledge and practice necessary to equip them for prescription work.

On the whole, I am one of those "simple-minded fellows" who believe that the Syllabus Committee has done wonderfully well with a most difficult problem, and if the members of the Committee continue their good and helpful work, the Syllabus will soon be of great assistance to pharmaceutical schools and teachers and a credit to all concerned.

HENRY P. HYNSON.

BROOKLYN, N. Y.

With much interest did the writer follow the discussions on the Pharmaceutical Syllabus at the A. Ph. A. Convention at Detroit, and also the minutes as published in the November number of the Journal.

The chief object of the Pharmaceutical Syllabus is to indicate the general scope and character of the instruction to be given by the teacher, and to outline the work to be done by the pharmaceutical student. It is an everlasting credit to the A. Ph. A. to have originated this splendid idea, which has resulted in a work which represents not only the A. Ph. A., but also the American Conference of Pharmaceutical Faculties, as well as the National Association of Boards of Pharmacy.

The National Syllabus Committee, thus formed, has so far published two editions of the National Syllabus. As was to be expected, the first edition of this book did *not* prove very satisfactory. However, pharmacists at large and quite especially the pharmaceutical educators in the United States had reason to expect that the second edition of the Pharmaceutical Syllabus would be a decided improvement. But to the great surprise of all of those looking for an *improved* edition, a sad disappointment resulted.

The writer has always taken an active interest in pharmaceutical education, and still more so since his appointment as Professor of Pharmacy, Pharmaceutical Chemistry, and History of Pharmacy in the Department of Pharmacy in the College of Jersey City. That the second edition of the Pharmaceutical Syllabus did *not* prove satisfactory to the Faculty of our College, can be seen from the following comments which have been published in our catalogue for the Session 1914 to 1915.

#### OUR ATTITUDE TOWARD THE PHARMACEUTICAL SYLLABUS.

The aim of the Pharmaceutical Syllabus is to outline a minimum course of study which would be broad enough and sufficiently well balanced to be acceptable as a basis of instruction to our schools of pharmacy and at the same time would be sufficiently extensive to be of use to our boards of pharmacy, to examine candidates for state conferred rights and privileges.

The Second Edition has been compiled by the National Committee of the Pharmaceutical Syllabus and published in June, 1914. Our College immediately appropriated a copy for each department. After careful consideration our faculty found itself heartily in sympathy with the objects of the Pharmaceutical Syllabus and considers the present, Second Edition a material improvement on its predecessor. However, our College is unable to *adopt* the Pharmaceutical Syllabus in its present status, in its entirety and for the following reasons:—

1.—Because no lectures are provided on the Theory of Pharmacy for the Senior year, which in our experience is a serious deficiency.

2.—Because the Syllabus for the subject of pharmacy provides during the Junior year only a total of 195 hours and for the Senior 205 hours. This time is entirely inadequate for a thorough course in this important branch of the work in order to provide the student with sufficient knowledge to take charge of a pharmacy in which drugs are dispensed and prescriptions compounded and also to pass the state board examination in a competent manner.

3.—Because as many as seventy-five hours are provided for Commercial Pharmacy and only sixty for Dispensing Pharmacy during the Senior term. This allotment of time is in the opinion of the Faculty unjust, as it lays too much stress upon commercialism and too little upon the professional side.

Nevertheless, in the arrangement of our courses, the Syllabus has been followed as much as possible and as far as in the opinion of our Faculty it was justified by experience and in accordance with our principles.

To the above comments, the writer may add the following personal ones:—

1.—In carefully looking over the second edition of the Pharmaceutical Syllabus, I find that only thirty-five pages are devoted to Pharmacy, while on the other hand, *Materia Medica*

occupies fully fifty-six pages. Let me ask the pharmaceutical educators and pharmacists in general if this is *fair* to the student at a school of pharmacy?

2.—Physiology occupies eleven pages and Dispensing Pharmacy only three pages! Just think of it!

3.—Posology, a Junior Study of but fifteen hours, occupies thirteen pages! Evidently, the gentleman who prepared this *outline* most certainly did *stretch* same!

4.—Last, but not least, Chapter VI, Reference Works, and Chapter VII, Text-books and Pharmaceutical Periodicals, both of which chapters occupy such a prominent place in the second edition of the Pharmaceutical Syllabus, are so full of mistakes, grammatical and otherwise, that they are certainly a disgrace to American Pharmacy. This latter fact has been so fully commented upon at the Detroit Convention, that it is unnecessary for the writer to dwell upon it any longer.

#### CONCLUSION.

In conclusion, I beg to state that the aim of the Pharmaceutical Syllabus is most certainly a laudable one. Let us hope that the third edition will be a great improvement upon its predecessors, and that it will prove satisfactory to our schools of pharmacy, and also to our boards of pharmacy. Up to the present time, there has been quite some confusion between the fact that the Pharmaceutical Syllabus is *sometimes adopted*, but *most generally only approved*!

Let us hope that the next edition of the Pharmaceutical Syllabus will be a master-work, which will be *adopted* by *all* the colleges of pharmacy and *all* the boards of pharmacy!

OTTO RAUBENHEIMER.

## DERIVATIVES OF SALICYLIC ACID.

JOHN W. FORBING, PH. C., B. S.

### ACETYLAMINO-SALICYLIC ACID AND ACETYLAMINOACETYL-SALICYLIC ACID FROM SALICYLIC ACID.

The following paper presents detailed methods for the production of the various acids which compose the steps of the synthesis. Interest is attached specially to acetylamino-salicylic acid  $C_8H_7(NHCOCH_3)OHC(=O)OH$ , in that its structural formula bears a resemblance to what might be termed, a composite of the active radicles of Phenacetin,  $C_8H_9O_2 \cdot C_2H_5 \cdot NHCOCH_3$ , and Aspirin  $C_9H_7COOH \cdot OC(=O)CH_3$ .

Acetylamino-salicylic acid forms soluble salts with  $NH_4$ , K, Na, Ca, and Sr. If tests indicate clinical usefulness, the product would have a decided advantage over the various insoluble varieties of Analgesics and Antipyretics.

The process of synthesis is based on the nitration of salicylic acid, the production and isolation of assymetric metanitro-salicylic acid (1-2-5) with liberal yield; the conversion of the nitro-salicylic into amino-salicylic acid hydrochloride and subsequent acetylation of the Amino and hydroxyl groups:—

Pharmacological, bactericidal and clinical factors are at present being determined by the Creighton College of Medicine and will be reported in the near future.

Assymetric metanitro-salicylic acid (1-2-5) is obtained by the following process:— 160 gm. potassium nitrate is placed in a 2000 cc. flask with 200 gm. sodium salicylate, and a solution of the salts is made with 600 cc. of water; 250 cc. of concentrated sulphuric acid is gradually and cautiously added, controlling the re-action by the affusion of cold water. After complete addition of sulphuric acid, the contents of the flask are poured into a spacious, porcelain evaporating-dish and 20 cc. of fuming nitric acid added, and the mixture allowed to stand for two hours. It is then heated on the water-bath for about one hour, in order to complete re-action, and allowed to stand in a cool place for twelve hours. The crystalline mass which separates out, is removed by means of a Buechner funnel and vacuum pump, and pressed free from mother-liquor. The mass is then dissolved, by boiling it in a solution of 130 gm. of sodium hydroxide in 750 cc. of water. The resultant dark-red solution is allowed to cool. There separates a reddish-brown mass composed principally of di-sodium-metanitro-salicylate,  $C_6H_3(NO_2)ONaCOONa.5H_2O$ . The mass is placed in a funnel, exhausted by vacuum and pressed. (The filtrate may be reserved, and vicinal nitro-salicylic acid, with a m. p.  $118^\circ$ , may be obtained by acidifying with HCl, boiling with purified animal charcoal, filtering hot, removing the cream-yellow crystalline mass which separates out on cooling, and purifying by conversion, into the K-salt. The K-salt is very soluble in boiling aqueous solution and, on cooling, crystallizes out in long, yellow, silky needles.)

The di-sodium-metanitro-salicylate mass is purified by solution in 500 cc. of boiling water, removal from source of heat and adding 200 cc. of methyl alcohol. On cooling, a bright uniformly-colored orange-red mass, crystallizes out, which is practically pure di-sodium-metanitro-salicylate.

Analysis of the mass washed with methyl alcohol, dried in air:—

Calculated for  $C_6H_3(NO_2)ONaCOONa.5H_2O$ .

0.5597 gm. substance—0.1589 gm.  $H_2O$  calculated—0.1508 gm. found.

0.2021 gm. substance—0.0677 gm.  $Na_2CO_3$  calculated—0.0708 gm. found.

The mass of di-sodium-nitro-salicylate yields the acid by placing it in 500 cc. of water, acidifying with HCl with an excess of about 150 cc., boiling and filtering while still hot. The acid is practically insoluble, in boiling water containing HCl, and remains on the filter as a yellow mass. This mass is washed with water and pressed, dissolved in boiling alcohol to which is added purified animal charcoal and filtered hot. The filtrate may be evaporated on a water-bath with a yield of 72 gm. of assymetric metanitro-salicylic acid in yellow prism crystals. Melting point,  $228^\circ$  with charring, (agreeing with data given in Richter's Organic Chemistry, Smith, vol. 11, p. 225).

*Analysis for Nitrogen:*—KJELDAHL-GUNNING METHOD:—

Calculated—N, 7.66%; found—N, 7.40%.

DUMAS' METHOD, *Technic*, Weyl (*Die Methoden der organischen Chemie, Allgemeiner Teil*, s. 34").

Calculated—N, 7.66%; found—N, 8.16%.

With potassium bicarbonate, the acid yields a salt crystallizing from hot aqueous solution in saffron-yellow needles; this salt dried two weeks *in vacuo* over  $\text{H}_2\text{SO}_4$  gave the following, potassium as  $\text{K}_2\text{SO}_4$ :—

0.45 g. Salt;  $\text{K}_2\text{SO}_4$ ; Calculated—0.1802. Found—0.1784.

The nitro-salicylic acid obtained by the above process is converted into amino-salicylic acid by reduction with tin and  $\text{HCl}$ .

50 gm. nitro-salicylic acid crystals is placed in a flask with 250 cc. of alcohol, 100 gm. tin and 200 cc.  $\text{HCl}$  added. The acid is added in portions of 50 cc. and the heat of reaction controlled by affusion of cold water. After addition of acid, an hour, is allowed for complete reaction:—

The contents of the flask are then heated until the white precipitate which is formed, is re-dissolved, and filtered hot. The alcoholic filtrate is evaporated, on the water-bath, to about two-thirds of its volume and allowed to stand for twelve hours. At the end of this time a large proportion of the double salt of the hydrochloride of the amino-acid and  $\text{SnCl}_2$  crystallizes out. The crystalline precipitate is separated and placed in 300 cc. of water and the tin separated with  $\text{H}_2\text{S}$ , filtered, and the filtrate evaporated on the water-bath. The amino-salicylic acid hydrochloride,  $\text{C}_6\text{H}_3\text{NH}_2\text{OHCOOH} \cdot \text{HCl}$ , crystallizes out in shining grayish-white crystals. By this process a portion of the amino-salicylic acid hydrochloride, remains in the filtrate and may be obtained by additional precipitation of tin with  $\text{H}_2\text{S}$  as  $\text{SnS}$  and  $\text{SnS}_2$ . The solution is filtered cold, to avoid re-solution of  $\text{SnS}_2$ , and the residue of sulphides containing a portion of the sparingly soluble amino-salicylic hydrochlorides, may be heated with water and filtered hot, the filtrate giving an increased yield of the hydrochloride.

Acetylaminoacetyl-salicylic acid is prepared as follows: 20 gm. amino-salicylic acid hydrochloride, is placed in a 100 cc. round-bottom flask and an excess of acetic anhydride added. The flask is connected with an upright condenser and heated on an oil-bath to 140–145° for one hour. The following re-action takes place:

$\text{HCl}$  is liberated and acetylation takes place with the gradual formation of a clear solution. The product of the re-action is poured into 150 cc. of water, and the greater amount of the acetic acid formed, due to excess of the anhydride used, is driven off by boiling and the water replaced. On cooling, clusters of white crystals of acetylaminoacetyl salicylic acid separate and are collected on filter and washed with cold water.

These crystals were purified for analysis by re-crystallization from alcohol.

Calculated for  $\text{C}_6\text{H}_3\text{NHCOCH}_2\text{O} \cdot \text{COCH}_2\text{COOH}$  N, 5.97%.

Found, 5.94, 6.07%.

This acid (acetylaminoacetyl-salicylic) has a melting point of 181°.

I found it impossible to produce a potassium salt of this acid. This acid gives no hydroxyl re-action with ferric chloride. On combining molecular weights of the acid and  $\text{KHCO}_3$  the hydroxyl is opened and acetic acid liberated and the K-salt of acetylamino-salicylic acid is formed. If this re-action takes place in the presence of ethyl alcohol, ethyl acetate is formed. The following equations account for action taking place:

Both acetylamino-salicylic acid and its potassium salt give a rich blue-coloration with ferric chloride.

If acetylaminoacetyl-salicylic acid is neutralized with potassium carbonate the K-salt of acetylamino-salicylic acid separates from a hot aqueous solution as a fine white powder. The K-salt, free from  $\text{H}_2\text{O}$ , gave the following results on analysis, determining potassium as  $\text{K}_2\text{SO}_4$  and assuming the formula to be  $\text{C}_6\text{H}_3(\text{NHCH}_3\text{CO})\text{OH}.\text{COOK}$ :—

0.5621 gm. K-salt;  $\text{K}_2\text{SO}_4$ ; found—0.2163. Calculated—0.2098.

0.0143 gm. K-salt;  $\text{K}_2\text{SO}_4$ ; found—0.0407. Calculated—0.0427.

If sodium acetate be added to acetylaminoacetyl-salicylic acid as a condensing agent, in order to introduce, by means of acetic anhydride, an acetyl radicle in the carboxyl group, there results a compound, crystallizing from water acidulated with  $\text{HCl}$  in silver-lustred laminae. This compound is undoubtedly the acetester of acetylaminoacetyl-salicylic acid; m. p.  $245^\circ$ . It is unstable and shortly after preparation gives acid re-action with potassium carbonate and a wine-coloration with ferric chloride. It crystallizes from alcohol in colorless prisms.

*Creighton University Laboratories, Omaha, Neb.*

#### TRANSATLANTIC TELEPHONY.

Mr. Marconi announces that an attempt to talk by wireless telephone from Carnarvon, Wales, to New York probably will be made within the next three months. Godfrey Isaacs, manager of the Marconi Company, testifying before the Dominion's Royal Commission on Imperial Communications, had said this feat probably would be accomplished before the end of the year, and he added: "I do not hesitate to express the opinion that if Marconi is able to telephone to New York he will, when the stations for wireless communication between this country and Buenos Aires are built, telephone to that city at the same time that he telegraphs."

Sir Rider Haggard, who is a member of the commission, anxious to follow up this peep into the future, asked Mr. Isaacs:

"You expect the time when a subscriber can have a telephone in his house by which he can telephone all over the world?"

Mr. Isaacs answered that he would not like to go so far as that. Many difficulties first would have to be overcome. It might be possible to go to a particular station in London and telephone to New York. There were great things yet to be revealed in the wireless business."—*Boston Transcript*.

## Of General Interest

### NATIONAL DRUG TRADES CONFERENCE.

PROCEEDINGS OF ANNUAL MEETING HELD AT THE NEW WILLARD HOTEL,  
WASHINGTON, D. C., DECEMBER 10, 1914.

President Wallace called the meeting to order at 10:30 a. m.

The Secretary called the roll of delegates duly accredited from their respective organizations.

*American Pharmaceutical Association:*

John C. Wallace, New Castle, Pa.  
Samuel L. Hilton, Washington, D. C.  
J. H. Beal, Urbana, Ill.

*National Wholesale Druggists' Association:*

Charles A. West, Boston, Mass. (absent).  
C. Mahlon Kline, Philadelphia, Pa.  
George W. Lattimer, Columbus, Ohio, represented by F. E. Holliday.

*National Association of Retail Druggists:*

Samuel C. Henry, Philadelphia, Pa.  
J. H. Reh fuss, Brooklyn, N. Y.  
J. F. Finneran, Boston, Mass. (absent).

*American Association of Pharmaceutical Chemists:*

Willard P. Stearns, Chicago, Ill., represented by George C. Hall, Brooklyn, N. Y.  
Dr. W. C. Abbott, Chicago, Ill., represented by Dr. Alfred S. Burdick, Chicago, Ill.  
R. C. Stofer, Norwich, N. Y.

*National Association of Manufacturers of Medicinal Products:*

Adolph G. Rosengarten, Philadelphia, Pa.  
Dr. A. R. L. Dohme, Baltimore, Md.  
Charles M. Woodruff, Detroit, Mich.

The minutes of the last meeting of the Conference were approved as printed.

The privilege of the floor was extended to Dr. W. C. Woodward, of Washington, D. C., representing the American Medical Association; Dr. M. I. Wilbert representing the Public Health Service, and Mr. J. Fred Windolph, of the Norwich Pharmacal Company.

The following report of the proceedings of the Executive Committee was read.

REPORT OF THE EXECUTIVE COMMITTEE.

A Meeting of the Executive Committee of the National Drug Trade Conference was held at the New Willard Hotel, Washington, D. C., December 9, 1914 in pursuance of a call of the President.

Meeting called to order by Chairman John C. Wallace at 11:45 a. m.

Present: John C. Wallace, Chairman; Charles M. Woodruff, Secretary; Samuel C. Henry, alternate for James F. Finneran; C. Mahlon Kline, and R. C. Stofer.

The minutes of the last meeting were read and approved.

Mr. Samuel C. Henry then presented his credentials as alternate for Mr. Finneran, and they were duly accepted.

Mr. Kline moved that a committee of three be appointed by the Chairman to draft a resolution respecting the matter of a regulation admitting medicinal poisons to the mails and report same to the afternoon session.

Motion seconded, put to vote and carried.

The Chairman appointed Messrs. Kline, Henry and Woodruff as such committee.

The following communication from the Council of the American Pharmaceutical Association was then read:

"At a meeting of the Council of the American Pharmaceutical Association held August 29, 1914, the following resolution passed by the House of Delegates and referred to the Council was approved:

"That the American Pharmaceutical Association instruct its representatives in the National Drug Trade Conference to act immediately in connection with the representatives of the large branches of the drug trade in the Drug Conference to draft at the earliest possible moment a bill to reform the present patent rights, registration of the names of drugs and the granting of sole right to sell certain drugs to the people of the United States, suitable to the best interests of the Drug Trade in the United States, and to urge its passage at the earliest possible opportunity, and the support of the A. Ph. A. is hereby pledged to such reform."

"The action of the Council was approved by the Association at the following general session."

Mr. Kline moved that the communication be referred to the Conference with the recommendation that the Conference appoint a special committee to consider the matter, and report at the next called meeting of the Conference.

Motion carried.

Secretary-Treasurer Woodruff then read the following financial statement:

<i>Receipts.</i>		
Balance on hand Jan. 9, 1914.....	\$135.55	
Sept. 4, 1914, by amount charged National Association envelopes....	2.34	
		<hr/> \$137.89
<i>Expenditures.</i>		
Jan. 13. Stenographer at New Willard.....	.50	
Feb. 2. Postage, 100 2's.....	2.00	
Feb. 18. Postage, 100 1's.....	1.00	
Feb. 28. Parke, Davis & Co., for mailing packages.....	.55	
March 2. 200 Reprints, January meeting .....	6.50	
March 5. Postage, 100 1's.....	1.00	
March 30. Parke, Davis & Co. for mailing brief on Harrison Bill to members of Congress.....	4.28	
April 8. 1000 printed briefs on Harrison Bill.....	20.00	
April 24. Postage, 100 2's.....	2.00	
Aug. 17. Postage, 50 2's....	1.00	
Sept. 4. Parke, Davis & Co.'s bill of March 5th for printing stationery .....	9.24	
Sept. 4. Parke, Davis & Co.'s bill of April 9, 1914, for printing resolutions of the Conference.....	13.76	
Sept. 10. Telegram sent Aug. 26th to J. Hampton Moore, Washington, D. C.....	.96	
Sept. 15. Postage, 50 2's.....	1.00	
Oct. 8. Postage, 25 2's.....	.50	
Nov. 7. Mr. Brokmeyer for telegrams sent, to Aug. 28th inclusive....	28.29	
Dec. 3. Telegram sent to Senator Townsend and Congressman Doremus respecting the Stamp Tax Bill.....	4.58	
		<hr/> 97.16
Balance on hand December 4, 1914.....		\$40.73

A communication from the Philadelphia Drug Exchange was received, and referred to the Conference.

The Committee then adjourned to meet in the Gridiron Room at 4 p. m.

The Executive Committee met pursuant to adjournment at the Gridiron Room, December 9, 1914, 4 p. m.

Present: The entire committee.

The minutes of the forenoon meeting were read and approved.

The special committee appointed to frame a resolution on a medicinal poison regulation then offered the following:

*Resolved*, That the National Drug Trade Conference hereby renews the representations and recommendations it has made in the past respecting the mailing of medicines containing poisons not outwardly or of their own force dangerous, and urges upon the Postmaster General the necessity of immediately promulgating a regulation in accordance with the letter and spirit of Section 217 of the United States Criminal Code, that will permit of the economical and prompt distribution of some of the most valuable medicinal agents which are now denied the mails, and for the lack of which in the hands of the medical profession and drug trade, particularly in small places, inaccessible to express offices, human health and even life is often imperilled.

*Resolved*, That the Secretary be and he is hereby instructed to send a copy of this Resolution to the Postmaster General.

C. MAHLON KLINE,  
S. C. HENRY,  
CHARLES M. WOODRUFF.

Prof. Beal moved that the resolutions be approved by the Committee and referred to the Conference with the recommendation that they be adopted.

Motion carried.

The probability of the Revision Committee of the United States Pharmacopœia adopting the cylinder-shaped, separately-wrapped bichloride of mercury pastille of the German Pharmacopœia was discussed by Dr. Dohme, Prof. Beal, Mr. Kline and others.

Mr. Kline moved that a special committee of three be appointed to frame a protest against the plan and present same to the Conference at its meeting.

Motion carried.

The Chairman appointed Mr. Kline, Dr. Dohme, and Prof. Beal as such committee.

Chairman Wallace asked if there was any objection on the part of any member to his inviting a representative of the Public Health Service, and a representative of the American Medical Association to meet with the Conference to-morrow. No member of the Committee objected.

Prof. Beal moved that the Executive Committee recommend that the Conference invite the Proprietary Association of America to send three delegates to the Conference in accordance with Section (2) of the Code of Rules and Regulations of the Conference.

Motion carried.

Prof. Beal moved that Mr. Henry, Mr. Stofer, and Mr. Woodruff be appointed a special committee to confer with Mr. Talbot, of the Internal Revenue Department, respecting forms of order blanks under the Harrison Bill.

Motion carried.

After some remarks of general interest, the meeting then adjourned to meet again at the call of the Chairman.

Report received and ordered printed in the proceedings of the Conference.

Dr. A. R. Dohme moved the adoption of the following resolution:

*Resolved*, That this Conference go on record as favoring a revision of the United States Patent and Trademark Laws, and that in accordance with the recommendation of the Executive Committee a committee of five be appointed to carefully consider the entire question after conferring with other National organizations that are similarly considering the same and report back their findings to a subsequent meeting of this Conference.

Motion carried.

The President appointed as such committee: Dr. A. R. L. Dohme, Mr. J. H. Rehfuß, Mr. George W. Lattimer, Prof. James H. Beal, and Mr. R. C. Stofer.

The financial report of the Secretary, as contained in the report of the Executive Committee, was read and approved.

Mr. Henry moved that the resolution recommended by the Executive Committee respecting a regulation admitting medicinal poisons to the mails be adopted.

Motion carried.

The special committee appointed by the Executive Committee to present a resolution to the Conference respecting the probable adoption by the Revision Committee of the United States Pharmacopœia of the mercury bichloride pastille of the German Pharmacopœia then offered the following:

WHEREAS, We are informed that the Revision Committee are considering favorably for adoption in the next edition of the U. S. Pharmacopœia the German standard for Bichloride Tablets, and

WHEREAS, We believe that the German standard which is a cylindrical tablet colored pink and wrapped individually in paper would be dangerous to the public health inasmuch as candies are often of similar shape and are so wrapped, and also that the wrapping of the tablets would be detrimental to the health of the employe engaged in the work.

THEREFORE, Be it resolved that the National Drug Trade Conference go on record as opposed to this standard for bichloride tablets and that a copy of this resolution be sent to each member of the Revision Committee.

C. MAHLON KLINE, Chairman.  
J. H. BEAL,  
A. R. L. DOHME.

Dr. Burdick moved the adoption of the resolution.

Motion carried.

Prof. James H. Beal then moved that the recommendation of the Executive Committee that the Proprietary Association of America be invited to send three delegates to the Conference in accordance with Section (2) of the Code of Rules and Regulations be approved and that the Secretary be instructed to send such invitation.

Motion seconded and unanimously carried.

Mr. Rosengarten moved that the Secretary be instructed to invite the American Medical Association to send three delegates to the Conference in accordance with Section (2) of the Code of Rules and Regulations.

Motion carried.

The communication received from the Philadelphia Drug Exchange and referred to the Conference by the Executive Committee was then taken up, and discussed, and Mr. Kline moved that a committee of three be appointed to draft a suitable resolution and present same to the Conference at its afternoon session.

Motion carried.

The President then appointed the following nominating committee: Mr. Rehfuss, Prof. Beal, Mr. Rosengarten, Mr. Holliday and Dr. Burdick.

Mr. Henry inquired if any member could authoritatively inform him whether a druggist who sold some items on a commission basis could be taxed as a commission merchant. The Secretary expressed the opinion that he could not, and Mr. Brockmeyer, who was present, read an analogous ruling confirming the Secretary's opinion.

Mr. Rehfuss moved that a special committee be appointed to file a protest with the Treasury Department against the double, and possible treble and quadruple taxation resulting from compelling the retail druggist to stamp packages he puts up from bulk packages already stamped and placed on his shelves.

Motion carried.

The President appointed Mr. Holliday, Mr. Rehfuss and Mr. Henry as such committee.

The Conference then adjourned to meet at four o'clock in the afternoon of the same day.

#### AFTERNOON SESSION OF THE CONFERENCE.

The Conference was called to order by the President, a quorum being present.

The Committee appointed to report to the Conference upon the communication received from the Philadelphia Drug Exchange then offered the following:

The committee to which has been referred the communication of the Philadelphia Drug Exchange respecting a proposed amendment of the section of the Federal Food and Drugs Act, governing the admission through the port of entry of drugs, the quality of which is under dispute or concerning the admissibility of which under the law there is a difference of opinion, respectfully report as follows:

1. The Committee is of the opinion that the evidence submitted indicates that, under existing practice, marked differences exist in the rulings at the different ports, whereby drugs which are refused at one port may be admitted at another.

2. That decisions regulating the admission of drugs are not enforced at all times at the same port of entry.

3. That the failure of the law to provide a method for review of the decision of the Secretary of Agriculture of the admissibility of a drug or chemical substance makes possible the existence of inequalities and lack of uniformity in drug importation, and may occasion instances of marked injustice to drug importers.

4. That the committee is not prepared at the present time to recommend a definite form of amendment for the correction of the faults referred to it, but does recommend that the whole subject be referred to a select committee of three, which committee should be instructed to cooperate with representatives of the Philadelphia Drug Exchange and of the Drug Trade Section of the New York Board of Trade and Transportation in an effort to obtain an amendment to that portion of the Food and Drugs Act which governs the admission to the United States of drugs submitted for entry, as will bring a substantial correction of the faults complained of.

J. H. BEAL,  
A. G. ROSENGARTEN,  
C. MATHON KLINE, Chairman.

On motion, the report was adopted and the committee was continued to act as the select committee referred to in the report. Dr. Beal declined to serve, and Mr. A. R. L. Dohme was appointed in his stead.

The committee appointed by the Executive Committee to interview the Commissioner of Internal Revenue respecting regulations, order forms, etc., under the Harrison Bill reported, verbally, that the Committee had been graciously received by Commissioner Osborne and referred to Mr. Talbot of the Law Division of the Internal Revenue office; that they had seen Mr. Talbot who expressed himself very anxious for the assistance and coöperation of the Committee; that the result of the interview was that Secretary Woodruff was to secure order blanks now used by the various manufacturers and wholesalers and submit same to Mr. Talbot that he might be guided thereby in determining the requirements of the trade also that Secretary Woodruff submit suggestions respecting the Record Book to be used under the Act.

On motion the report was accepted and approved and the committee continued to complete its work.

Mr. Stofer moved that each constituent association be assessed \$50.00 to replenish the funds of the Conference.

Motion carried.

Mr. Henry moved that the Conference approve the Stevens Bill to secure price protection, being H. R. No. 13305.

Motion carried.

Dr. Dohme moved that the Secretary be instructed to cable Governor General, Francis Burton Harrison of the Philippine Islands, congratulations on the passage of the Harrison Bill.

Motion carried.

The Committee then reported the following nominations:

President, Mr. John C. Wallace.

First Vice-President, Mr. Charles A. West.

Second Vice-President, Dr. Wallace C. Abbott.

Third Vice-President, Mr. James F. Finneran.

Secretary-Treasurer, Mr. Charles M. Woodruff.

#### EXECUTIVE COMMITTEE.

N. A. R. D., Mr. Samuel C. Henry.

A. Ph. A., Prof. James H. Beal.

N. W. D. A., Mr. C. Mahlon Kline.

N. A. M. M. P., Dr. A. R. L. Dohme.

A. A. Ph. C., Mr. R. C. Stofer.

On motion, the Secretary cast the ballot of the Conference for the persons named and they were declared elected.

On motion, the Conference then adjourned to meet at the call of the President, in accordance with the Code of Rules and Regulations.

CHARLES M. WOODRUFF,

Secretary.

Edward Hance Hance, founder and senior member of Hance Bros. and White, Inc., of Philadelphia, died on December 14, 1914, at the Germantown Hospital. He was eighty-one years old and had been ill for some time.

Mr. Hance had a long and active career. He was born in the Quaker City on November 1, 1833 and received his early education at a private school at Gwynedd, Pa. Later, he returned to Philadelphia, and entered the employ of Gilbert, Wentz and Co. and of Charles Ellis, Son & Co., and became a student at the Philadelphia College of Pharmacy, from which he was graduated in 1851, the subject of his thesis being *Chimaphila umbellata*. He had as his classmate the late John Wyeth, both of them destined to become important figures in American manufacturing pharmacy.

In 1855 Mr. Hance engaged in the manufacture of pharmaceutical and medicinal products on a large scale, the plant being first located near Fourth Street and York Road, in 1857 on Arch Street and 1860 at 509 North Street. Manufacturing Pharmacy was then in its infancy. In 1860 he formed a

co-partnership with Mr. J. Clarkson Griffith under the firm name of Hance, Griffith and Co. The business of the firm grew rapidly and in 1867 the plant was moved to Callowhill and Marshall Streets, where it is still located. In 1869 Dr. James W. White became associated with the firm, and it became Hance Bros. and White, continuing as such until its recent incorporation as Hance Bros. and White, Inc.

Mr. Hance early identified himself with organization work. He became a member of the Philadelphia College of Pharmacy in 1857, and in the same year joined the American Pharmaceutical Association, becoming a life member.

But it was in the work of the Philadelphia Drug Exchange that he took the deepest interest. Elected as a member of the Board of Directors in 1869, he served as such for several years, and in 1873 was made President. During the following four years, he was an active member of the Board of Directors. With Mr. Alexander H. Jones and Mr. H. B. Rosengarten, he was most zealous in securing protection for the drug and chemical industries of the country and promoting their development. He devoted a great deal of time to the subjects of Mutual Fire Insurance for Manufacturers and Wholesalers and tax free alcohol for use in the Arts. He rendered especially valuable services at the time of the Centennial Exposition in pointing out the possibilities of growth of American manufacturing pharmacy. To his efforts and skill is credited most largely the wide spread advertising that Philadelphia-made pharmaceuticals have received, both in this country and abroad.

In 1878 he was elected Treasurer of the Exchange and was continued as such until 1896, when he was, for the second time, made President. The following year he was again elected Treasurer and was continued in that office until his demise; a total period of service as Treasurer of thirty-six years.

He was one of the earliest members of the Union League, but resigned some years after the Civil War was over, and was an active member of the Philadelphia Board of Trade. He was a prime mover in the organization of the Philadelphia Bourse, being in hearty accord

\*It is a curious coincidence that the photograph used in making the illustration of this sketch was taken by F. Gutekunst, of international fame as a photographer, who was a member of the class of 1853 of the Philadelphia College of Pharmacy.

with the objects of that organization and actively working to make Philadelphia and its manufacturing industries most widely known.

He took, also, a deep and active interest in the management of the Germantown Hospital, of which he was a director for many years.

Mr. Hance was widely esteemed for his many lovable qualities of character. "To a large circle of friends," as has been stated, "his death has its personal, poignant regret; to the mercantile and commercial world it marks the cessation of an active force which was of strong influence in the development and upbuilding of a large and important business; while to the community in general it completes a career of effort, and enterprise that was exceptional in its fruitful accomplishments and achievements."

Mr. Hance is survived by two sons—Anthony M. Hance and Edward H. Hance, Jr.

The funeral services were held at the late residence of the deceased, 104 West Tulphocken Street, Germantown, Philadelphia, on Thursday, December 17th, 1914.

The services were conducted by Rev. Dr. C. H. Arndt, rector of Christ Protestant Episcopal Church, Germantown, and Rev. Dr. Samuel J. Upjohn, rector of the Lasher Protestant Episcopal Church, Germantown.

The honorary pallbearers were: William M. Coates, president of the Board of Trade; Harry H. Good, of New York; Harry B. Rosengarten, president of the Powers-Weightman-Rosengarten Company; Judge William H. Staake, of Common Pleas Court; Francis D. Gowen, General Counsel P. R. R.; George E. Bartol, president of the Philadelphia Bourse; Joseph C. Fraley, of Fraley & Paul, lawyers; William R. Tucker, secretary and assistant treasurer of the Philadelphia Board of Trade, and Consul for Russia; Harry B. French, president of Smith, Kline & French Co.; Dr. Richard V. Mattison, president of Keasbey & Mattison Co.; Richard M. Shoemaker, head of Robert Shoemaker & Co.; Walter V. Smith, president of Valentine H. Smith & Co.; A. Robinson McIlvaine, treasurer of Edward G. Budd Manufacturing Co.; Edward H. Long, head of John H. Long & Co.; Harold E. Gillingham, broker; Prof. Robert W. Blake; Thomas H. Shoemaker, and Harry A. Eveleth.

J. W. E.

#### GEORGE MERRELL.

*"God's Finger Touched Him and He Slept."*

On December 12, at his home in Cincinnati, George Merrell, the President of the William S. Merrell Chemical Company, "passed out of the shadow" into eternal rest.

Born in 1846, George Merrell had attained nearly the Scriptural limit of "three score and ten," rounding out a life full of Faith and Charity and Love for all Mankind, and his passing-away was one of those solemn lessons to all that our sands of life are running rapidly, and that we too, like him, should try to leave behind us "foot-prints on the sands of time," that will be of service to our fellows and to all Humanity.

Sprung from a brave New England ancestry, George Merrell embodied in his character, the sturdiness and firmness of the Puritan mingled with the geniality and the sympathy of the aristocracy of the Colonial life, in which brotherhood was felt more than in these material days. A son of a pharmacist, he knew the life and the work of a pharmacist, and thus could enter into intimate relations with the men of his profession.

The Civil War changed his course in life as it did that of many other young men of that trying period. He became a business man rather than a professional one, and developed the firm of the William S. Merrell Co., until it is known thruout the world for the reliability and efficiency of its drug-productions.

He was a 32° Mason, a charter member of the Society of Colonial Wars and the Sons of the Revolution, and an honorary member of many of the pharmaceutical associations in the country. He leaves a widow and three sons. They are Stanley W. Merrell, Judge of the Superior Court; Thurston Merrell and Charles G. Merrell. The following named gentlemen represented the Cincinnati Branch of the A. Ph. A. at the obsequies on Tuesday, the fifteenth ult:— Professors John Uri Lloyd, Charles Apmeyer, Theo. Wetterstroem, C. T. P. Fennell, Dr. A. Zwick, and Messrs. Fred Weissman, D. E. Murphy, Louis Werner, Frank H. Freericks, E. J. Voss, E. L. Picket and E. H. Thiesing.

## NECROLOGY.

## GUSTAVUS A. KNABE.

Gustavus Alexander Knabe was born at Maryville, Tenn., July 8, 1853, and moved to Knoxville when only a few years old.

When but sixteen years of age, he entered the drug business as clerk for Chamberland and Albers, of Knoxville, Tenn.

He was graduated from the Maryland College of Pharmacy, class of 1876, and after having worked in the Gay Street Store of Charles Caspari, Jr., of Baltimore, removed to Washington, D. C., where he was employed at the National Hotel Drug Store, then conducted by Scheler and Stephens. After leaving Washington, he served for three years as apothecary on the U. S. S. "Vandalia."

In 1887, he purchased a store at Montgomery, Ala., and with his brother, Henry F. Knabe, conducted a most successful business up to the time of his demise.

Gus Knabe joined the American Pharmaceutical Association in 1876, becoming a life member in 1913.

He was an ardent Mason, holding several offices in his lodge; and was, also, a Knight Templar and a member of the Shrine.

He was a master of his daily work, brought honor upon his craft and won the esteem of all who came to know him.

J. W. E.

## THE ALPERS BANQUET.

The Northern Ohio Branch and the Cleveland School of Pharmacy tendered a complimentary banquet to Dr. and Madam Alpers on the evening of December 2., in recognition of the election of the doctor to the highest office in the gift of American Pharmacy, that of President of the American Pharmaceutical Association as briefly noted in the last issue. The occasion was one which was memorable in American Pharmacy and calls for more complete mention.

Among the guests were all those prominent in Cleveland Pharmacy, of whom may be mentioned: Mr. and Mrs. L. C. Hopp, Prof. and Mrs. J. Spenzer, Prof. P. G. Albrecht, Mr. and Mrs. John Krause, Mr. and Mrs. Wm. Hankey, Mr. and Mrs. Marshall, Mr. and Mrs. Carl Schmitt, Mr. and Mrs. Hechler, Mr. and Mrs. Petersilge, Mr. W. H.

Gillmore, Mr. and Mrs. F. Pratt, Mr. and Mrs. Albrecht.

Mr. Lewis C. Hopp presided over the post-prandial exercises and welcomed the guests in an eloquent address testifying to the regard and esteem with which Dr. Alpers is held by the drug-world of Cleveland. Letters and telegrams were read from Prof. Joseph P. Remington, ex-President, G. M. Beringer, Prof. H. V. Army, Geo. C. Dickman, Robert S. Lehman, Hugo Kantrowitz, Felix Hirsman, and Romaine Pierson of New York; Eugene P. Selters and Carl Winters of Cleveland, and Geo. B. Kauffman of Columbus, Ohio.

The various drug-interests of Cleveland were particularly represented by Mr. William T. Hankey, the Wholesale Druggists; Mr. E. Petersilge, the Retail Druggists; Mr. John Krause, the Cleveland School of Pharmacy; Professors Spenzer and Albrecht, the Faculty; Mr. Joseph Albrecht, the Mummi Association, and Mr. Henry Mitchell, the Student Body.

Dr. Alpers responded to their felicitous addresses as follows:

Your kind invitation to meet you here at this festive board was received with mingled feelings of embarrassment and pride. I am fully aware of the high honor that such a gathering confers, and deeply recognize the distinction that the receiver of this honor carries with him. I have asked myself again and again, if I really deserve such an elevation, and am afraid that my ability to serve you and the cause of pharmacy has been overrated and your friendship coming from the fullness of your good hearts has gotten the best of your sober judgment of my worth. This embarrassment, however, is coupled with pride, and I hope justified pride, that such a distinguished gathering as yours should have selected me for this high honor. It is therefore in the full recognition of your kindness and the sincere appreciation of your goodness that I express to you all my heartfelt thanks for this beautiful token of your friendship.

The immediate cause for this testimonial is my election to the presidency of the American Pharmaceutical Association. This office is considered by most as the highest honor within the gift of American Pharmacy and is valued accordingly by all members. I am particularly gratified at my election just at this time for the reason that the year of my presidency will be the twenty-fifth anniversary of my membership. I know that to a great extent I owe my nomination to my dear friend, Mr. Lewis C. Hopp, our genial toastmaster, who himself is an ex-president of the Association. My election by a handsome majority showed me the love and esteem of my

fellow members in the Association and I may be pardoned to confess that the moment when I received the announcement of the vote was one of the happiest of my life.

Of all earthly goods I value my membership in the American Pharmaceutical Association the highest. It has been to me a source of infinite joy, satisfaction, learning, instruction, inspiration and blessing. From the first moment that I entered the meeting of the Association—it was at the memorable meeting at the Profile House in the White Mountains—I knew that I had joined a circle of men with whom to associate was a pleasure, a benefit, an honor. I at once saw the immense field of work that this Association had laid out for its loyal members and I also recognized my own shortcomings. But the revelation that this first meeting brought me, became a spur to work, to study and try to become a peer or even a leader among these men of the highest type. It taught me by a convincing lesson that strict loyalty and upright faithfulness to the higher causes of pharmacy would alone be able to battle with the many impeding obstacles and that this battle was a worthy object, and victory the highest ideal, of a true pharmacist's life. This first impression has never left me, it has become firm conviction and will remain with me as long as I live. In this sense I have worked and fought in the councils of the Association, always true to my convictions, and fearless when I had recognized what I considered true and right. Not that I claim that I always was right; nobody can say that he is right all the time, but no matter how different the opinions of leading men were, how fiercely the battle of argument was waged, I never thought less of my opponents, listened to their words with respect, and weighed them carefully. It is thus that truth and right will come to the surface and finally prevail. And how wonderfully do such battles of brains and conviction shine in comparison with the battles of a terrible war, where victory and murder become identical and the destruction of the works of civilization is called a great deed. Here both gain, victor and vanquished, and far from hating or despising each other, become true friends by the recognition of each other's worth and courage. This loyalty and devotion to the causes of pharmacy shall be the guides during my presidency and with the aid of my fellow officers and friends I hope to become a worthy successor to the many excellent presidents that have in the past shaped the destinies of the American Pharmaceutical Association.

I cannot close my remarks without adding a few words to you, my Cleveland friends, in special and tell you how deeply I am affected by your kindness this evening. It is not quite a year that I came to you, unknown to most of you, and took charge of the School of Pharmacy. From the very first day I met with the kindest welcome and warmest reception by all. Pharmacists, students, trustees, fellow-teachers, and also the ladies of Cleveland, the sweet pharmacists,

seemed to envy with each other to make my stay pleasant and my work successful. And when I saw the great opportunities that Cleveland presented to a loyal and earnest teacher, I at once knew that I had found the right place. I plunged into my work with enthusiasm and energy. I gave the students the best that was in me, and watched over each one with the love and full interest that my responsible position demanded. I have been every day, since my arrival, the first one at the school in the morning and the last one at night, believing that a Dean's loyalty requires him to devote his whole time to the great and beautiful work that such an institution affords. I have prepared every lecture carefully and conscientiously and endeavored through word and example to implant into the hearts of the students a deep-seated love for their profession and devotion to their work. In this ideal conception of my duties, I have received the support and assistance of the trustees and members of the school and we have, by joint work and efforts, been able to create a beautiful and flourishing college. But, I consider the present success only the beginning of my work, and hope that each year will surpass the preceding one in good results.

After these words, I need not tell you that I feel happy here in Cleveland, in your midst, and I assure you that this gathering, and this beautiful token of your friendship and esteem, will be a new inspiration to serve you and pharmacy better and more faithfully than before.

## Proceedings of the Local Branches

### CHICAGO.

The regular monthly meeting was held Tuesday evening, December 15th, following a dinner in honor of Dr. J. H. Beal, who, on account of his recent change of residence to Illinois, now becomes a member of the Chicago Branch.

At the meeting were gathered representatives of the various pharmaceutical interests of Chicago, to discuss proposed amendments to the state pharmacy law. The meeting was especially timely as an important conference of the pharmaceutical interests of the state will be held in January at Springfield, under the auspices of the State Board of Pharmacy, with the aim of framing desirable amendments to the Illinois pharmacy law.

President Jas. H. Wells presided and introduced Mr. Leo. L. Mrazek, of the State Board of Pharmacy, who presented for discussion

the recommendations of the Board in its recent report to the Governor. These recommendations embraced, first, certain changes in the anti-narcotic sections to make them conform to the model "anti-narcotic" law. In the discussion that followed, Mr. Thos. Potts read the anti-narcotic sections of the Indiana Law, and stated that excellent results in suppressing the illegal use of narcotics were being had under this law. Messrs. Irwin A. Becker, S. K. Sass, H. C. Christensen and others favored the changes in the anti-narcotic sections as recommended by the State Board.

The second recommendation of the Board was as follows:— Making it unlawful for any individual to have in his possession more cocaine or eucaïne than can be obtained by means of prescription from a regularly licensed physician, exception to be made in the case of registered pharmacists, physicians, dentists, veterinarians, and hospitals. In the discussion, in which Messrs. J. Riemschneider, Hugh Craig, C. E. Storer, and others participated, it was pointed out that physicians' prescriptions not unfrequently called for undue amounts of cocaine.

The third recommendation—that of a college pre-requisite requirement from candidates for examination as registered pharmacists, after a brief discussion by Professor W. B. Day, was unanimously adopted.

A fourth recommendation—a penalty for false representation as to being registered in Illinois as apprentice, assistant pharmacist or registered pharmacist, was adopted.

Dr. Beal told of some of the activities of the Drug Trade Conference meeting just concluded in Washington. The chief matters of discussion were the operation of the Harrison Bill, recently passed by Congress, the various stamp tax decisions; the evils of law making by bureaucratic rulings and the need of modification of our present patent laws.

Mr. Light spoke of the protest made by the Chicago Retail Druggists' Association against a proposed bill to be presented to the legislature at Springfield, by the Chicago City Council, to empower it to license, tax and regulate drug stores.

A nominating committee, consisting of Messrs. Gray, Becker and Sass, to report previous to the annual election of officers, at the next meeting of the Branch, was elected. Upon motion, also, the date of the next meeting was changed from Tuesday, January 19th,

to Friday evening, January 22d, so as to enable members in attendance at the Springfield Conference, January 18th and 19th, to be present and report at the Branch meeting.

E. N. GATHERCOOL, Secretary.

## CINCINNATI.

The regular monthly meeting was held at Lloyd Library, December 15. President E. H. Thiesing occupied the chair. The minutes of the last monthly meeting were approved.

The President announced the death of our esteemed member, G. M. Merrell. The following members had been appointed to pay the last respects of the local branch at the funeral service:— Messrs. D. E. Murphy, Frank H. Freericks, Louis Werner, Edw. Voss, Jr., C. T. P. Fennel, C. A. Apmeyer, E. W. Weissmann, E. H. Thiesing, J. U. Lloyd, Theodore Wetterstroem.

On motion of Frank H. Freericks, the President selected Prof. J. U. Lloyd as chairman, with Frank H. Freericks and Julius Greyer, to act as a committee to frame a suitable resolution of condolence on the death of Mr. Merrell.

Mr. Frank H. Freericks, as chairman of the Committee on Legislation, spoke of the advanced legislation contemplated on the sale and distribution of narcotic drugs.

Prof. J. U. Lloyd, as chairman of the Committee on National Home, spoke of the advantages of Cincinnati for the selection of a site for same.

Miss Bertha Ott presented an excellent and exhaustive paper on "Belladonna," treating her subject from an historical, pharmaceutical and medical standpoint, and also giving quite a few facts and possibilities, regarding the cultivation and preservation of this valuable drug.

Miss Ott received a vote of thanks and was highly complimented on this excellent paper. The Secretary was directed to forward same to the Editor, with a request to have this paper published in the Journal.

Mr. Wetterstroem suggested that pharmacists and government officials should use their influence and help to instruct the intelligent and willing farmer, through the "Farmers' Institute," upon the importance and feasibility of cultivating medicinal plants.

Prof. Lloyd emphasized the importance of the history and origin of a drug and asserted

that a great many valuable remedies were originally brought to the notice of the scientific man from outside sources.

The discussion was participated in by several other members, after which the President called upon Mr. Chas. Ehlers, who chose for his subject, "Discussion on U. S. P. and N. F. Preparations." Among others, he took up the Glycerite Iron, Quinine and Strychnine, setting forth that by changing the proportion of the glycerine and water, in a slight degree, a much more permanent preparation will be obtained. He also referred to Syrup Wild Cherry, Liquor Cresolis Comp., Liq. Antisept. Alkal., Elixir Digestiv. Comp., Elix. Iron, Quinine and Strychnine, claiming, improvement may be had by slight changes either in formulas or modes of preparation.

He proposed a modified formula for preparing Solution Aluminum Acetate, stating a permanent 7% solution may be obtained by the following:—

Lead Acetate .....	600 grains
Alum .....	360 grains
Sodium Sulphite .....	60 grains
Water—ad .....	10 fl. ozs.

An interesting discussion resulted, regarding these preparations, which was taken part in by Messrs. Lloyd, Wetterstroem, Apmeyer, Freericks, Grey and others.

CHAS. A. APMEYER, Secretary.

<>

#### COLUMBUS.

The December meeting was held in the Y. M. C. A. rooms on Wednesday evening, December 9, with President Topping in the chair. The principal address of the evening was made by Mr. Charles P. Hoover, the chemist in charge of the filtration plant of the water supply of the city. His address was a most interesting description of the treatment of an unsanitary water, to make it potable and sanitary, and was accompanied with demonstrations of the effect of certain chemicals upon the river water-supply, and was also illustrated with charts.

An interesting discussion on Parliamentary Law was evoked by the presentation to the Branch of a copy of the latest edition of Cushing's Parliamentary Practice by Mr. Marshall, during the course, of which, many amusing blunders in parliamentary practice in pharmaceutical meetings were stated and criticized.

Dr. C. A. Dye reported the organization of the Membership Committee and stated that the outlook at this time was favorable.

Mr. Young reported for the Joint Committee with the O. S. P. A., on the Medicinal Plant Garden for the University. He stated that the committee were working with the matter and had made a good start. That they were at the present time going over some literature and statistics and he would have a report by the next meeting that would be of more interest to the Branch.

Dr. Dye reported for the Program Committee that the program for the winter had been practically completed and that the Branch would hear some good papers and some good addresses by quite a number of interesting speakers. He further stated that, the speakers would not be all pharmacists but that several chemists in other lines of work had promised to address the Branch.

Dr. Dye presented a written motion to amend the By-Laws that Chapter IV, Article 1 of the By-Laws be amended to read that "Regular meetings shall be held on the second Wednesday of each month."

This motion was received and according to the Constitution will be voted upon at the next meeting.

The President then made a few remarks of welcome to the university students who were in attendance at this meeting, and assured them that they were welcome and that the Branch would be glad to have them attend as many meetings of the Branch as they could.

Dr. Dye then moved a vote of thanks by the Branch to Mr. Hoover and stated that this was one municipal enterprise that had been run without a stain. Seconded by Mr. Young. Unanimously carried.

Dr. Dye moved that the meeting of the Branch adjourn to meet the second Wednesday in January. Seconded by Mr. Will. Carried.

Adjourned at 10:15.

EDWARD SPEASE, Secretary.

<>

#### DETROIT.

The Detroit Branch was organized on December 11, 1914, and the following officers were elected:—

President, W. A. Hall; Vice-President, A. A. Wheeler; Secretary, Wilbur L. Scoville;

Treasurer, C. F. Mann; Representative on the Council, L. A. Seltzer.

There was a goodly attendance of the Detroit A. Ph. A. members, and it was decided to hold meetings monthly. Mr. H. B. Mason is the chairman of the Program Committee for the year, and a Committee on By-Laws is expected to report at the next meeting, on January 20th.

Dr. E. R. Larned inaugurated the scientific course by an illustrated lecture on Opsonins and Bacterial Vaccines.

The influence of bacteria and bacterial products on the human system was described and illustrated, and the method for taking the opsonic index of a patient given in full. The manufacture of bacterial vaccines was then described fully and some suggestions given for their use. A lively discussion followed the lecture.

Detroit and Ann Arbor both contain an abundance of able talkers and some very interesting papers are expected in the near future. Ann Arbor is included in this Branch, as are the other near-by towns.

WILBUR L. SCOVELLE, Secretary.

#### NEW YORK.

The November meeting of the New York Branch of the American Pharmaceutical Association was held on the evening of the ninth. The meeting opened with President H. V. Arny in the chair.

On motion duly carried, the reading of the minutes of the previous meeting was dispensed with.

Treasurer Weinstein read his report, which was approved.

T. D. McElhenie, reporting for the Council, stated that there had been considerable discussion as to the feasibility of the American Pharmaceutical Association participating in a pharmaceutical exhibit at the coming Panama-Pacific Exposition at San Francisco. Certain members of the Council were in favor of the association making an exhibit, while quite a large percentage of the Council questioned whether or not it would be of sufficient interest to the general public to warrant the expense. C. O. Bigelow, in commenting on Mr. McElhenie's report, stated that the New York College of Pharmacy as an institution had voted against the working exhibit proposition last winter.

No reports were made for the Education

and Legislation, Progress of Pharmacy, Membership, or Fraternal Relations Committees as the Chairmen of the various committees were absent. Dr. Dickman, Chairman of the Progress of Pharmacy Committee, sent a note explaining that he was ill and for that reason unable to attend.

The Secretary then read a communication from J. W. England, Secretary of the Council of the parent body, to the effect that papers prepared by A. Ph. A. members must be reserved for initial publication in the Journal of the American Pharmaceutical Association.

President Arny suggested that a dinner should be given in honor of Mr. Caswell A. Mayo, President of the parent association, and C. O. Bigelow made the motion, which was duly seconded and unanimously carried, and it was decided that the dinner should be given some time during the early part of January and that the various local pharmaceutical associations should be asked to co-operate with the New York Branch in tendering the dinner to Mr. Mayo.

Dr. Arny suggested that the local Branch invite Dr. Edward Kremers of the University of Wisconsin to address the members on "The History of Pharmacy" but, after the matter was discussed, it was decided that the New York College of Pharmacy endeavor to have Dr. Kremers give his lecture at one of their early meetings.

The speaker of the evening, Joseph L. Turner, was then introduced and a very interesting paper prepared by himself and Mr. Ralph C. Holmes on "Estimation of Cineol in Oil of Eucalyptus" was read and illustrated. This paper will be printed later in the Journal. It was discussed by Messrs. Raubenheimer, Murray, Mansfield and Wimmer.

Dr. Mansfield was asked to discuss the eucalyptus leaf from a botanical viewpoint, which he did, and at the same time he displayed a specimen of the prime eucalyptus leaf.

Otto Raubenheimer moved that a copy of the paper presented by Messrs. Turner and Holmes be promptly forwarded to Professor Joseph Remington, Chairman of the Committee of Revision of the U. S. P., which motion was carried.

Upon the motion of Dr. William Mansfield, Messrs. Turner and Holmes were given a vote of thanks.

Under the heading of new business, T. D.

McElhenie displayed a bottle of Rhodes Astringent Hair Lotion, the carton and label of which both indicated that the product contained 40 per cent. methyl alcohol. The preparation is manufactured by Arthur Rhodes, Lowell, Mass. He called attention to the deleterious effect of methyl alcohol when used internally or externally and expressed his surprise that any manufacturer should be bold enough to use methyl alcohol in the preparation of a product such as a hair tonic or lotion. He further called attention to the fact that in Greater New York such a product could not be legally sold and indicated that the same applied in a great many other sections.

The meeting was then adjourned.

FRANK L. MCCARTNEY, Secretary.

#### PHILADELPHIA.

The regular monthly meeting was held on Tuesday evening, December 8, at the Temple College of Pharmacy.

In the absence of President E. Fullerton Cook, Vice-President J. W. Sturmer called the meeting to order at 8:15 p. m. The minutes of the last meeting were read and approved.

A communication from The Pearson Publishing Company, in answer to the resolution passed at the November meeting, concerning the article, "Pills and Piracy," in Pearson's Magazine, was read. The full text of the letter is as follows:—

Dear Sir:—We acknowledge receipt of your letter of the 16th inst. We can express no regret at the publication of the article to which you refer. The chief complaint of pharmacists seems to be that the author of the article knows nothing about pharmacy. That's just the point. The average man knows nothing about pharmacy, but no pharmacist has denied that it is a practice to charge more for the simplest medicines when a doctor's prescription is presented than is charged when a man merely asks for the medicine. No pharmacist has given us a good reason for this.

However, we want to be right about this as we want to be right about everything else. We have offered space to various pharmacists for an article on the other side of the matter. We offer such space to you.

Yours very truly, (Signed)

THE PEARSON PUBLISHING COMPANY.

It was moved by Prof. C. H. LaWall that a committee of three be appointed to draw up an answer to this letter. The motion car-

ried and the following committee was appointed for that purpose:— Prof. LaWall, Franklin M. Apple and Charles Leedom.

The program of the evening was then taken up and Mr. Harry B. French discussed "The Influence of the European War on the Supply and Cost of Drugs and Chemicals."

Dr. George H. Meeker read a paper on "Vitamines in Their Relation to the Complete Diet."

"The Review of Current Pharmaceutical Literature" was presented by Prof. Freeman P. Stroup.

A vote of thanks, as proposed by Mr. J. W. England, was given to the contributors of the program, after which the meeting adjourned.

Respectfully submitted,

J. ED. BREWER, Secretary.

#### PITTSBURGH.

The Branch held its first meeting for the season of 1914-15, Friday evening, December 11th.

The attendance was encouraging and the proceedings exceptionally instructive and interesting.

The program consisted of the following promising subjects for elucidation and discussion: "Diatoms," (illustrated), by Dr. L. K. Darbaker and Dr. F. J. Blumenschein, "The War Tax," by B. E. Pritchard. "A Note on Zinc Oxide Ointment," by Dr. Louis Emanuel.

The illustrations thrown upon the canvas of the many beautiful markings to be found on diatomaceous earths were greatly appreciated, and were a source of surprise and wonderment at their number and range of variation. The descriptive talk by Dr. Darbaker was helpful in directing attention to these markings, while the character of the various kinds of these earths and the sources from which they are obtained by Dr. Blumenschein, were both appreciated by the audience. In the discussion following, many astonishing features concerning these earths were brought out, showing what an intensely interesting study they constitute. In this discussion Dr. J. A. Koch, President Andrew Campbell and Dr. J. H. Wurdack participated, and each speaker disclosed a wide knowledge of the subject that was another surprise, as most of those present were hearing all these things for the first time.

The "War Tax" talk was a feature that

came a little closer to the every-day things that occupy our thoughts in business problems, and the speaker said, that this measure is a problem in its complexities that "no fellow can find out" is not to be questioned. It is the consensus of opinion that "it is a piece of legislation that was entirely uncalled for, and only carried out as one more way out of the woods for the administration to cover up the damage done by the last Tariff law." Analysis of the measure in its text, shows it to have been very loosely and carelessly drawn, and reference to the various rulings issued by the Internal Revenue Department, taken in connection with the law in its wording, shows many inconsistencies and absurdities. Attention was directed to the good work of the various drug trade organizations in succeeding in having so-called patent medicines eliminated from the provisions of the bill, which was appreciated.

Dr. Emanuel's Note on "Zinc Oxide Ointment" dealt with the action of the U. S. P. Revision Committee, retaining benzoated lard as a base for zinc oxide ointment, and the opposition to that action among many pharmacists because of its proneness to rancidity, which is not the case where petrolatum is used. Dr. Emanuel favored the lard-base, for reason that the ointment under discussion has gained its wide reputation as a healing agent under the use of that base, and should petrolatum not prove as therapeutically efficient as a base, this popular medicament may lose its reputation, and thus one more old, time-tried remedial agent will be forced out of our materia medica. Dr. Emanuel called attention to the wide use of the petrolatum base, and warned pharmacists that its use may lead to prosecution under the Federal drugs act, as well as under the drugs acts found on the statute books of a number of states.

The Committee on Nomination of Officers to be voted for at the January meeting presented the following slate: President, George W. Kutscher; First Vice President, Peter G. Wiber; Second Vice President, Leonard K. Dathaker; Third Vice President, Jesse J. DeLoe; Secretary, Benjamin F. Pritchard; Treasurer, P. Henry Fred; For chairman of the various committees: Program, Frederick J. Blumenschen; Publicity, B. E. Pritchard; Practice, Louis S. Allee; Membership, J. H. Wardick; Education and Legislation, Andrew Campbell; Medical Re-

lations, Albert F. Judd; Member of Council, three-year term, Julius A. Koch.

B. E. PRITCHARD.

#### SAINT LOUIS.

Thirty-five members were in attendance at the meeting of the Saint Louis Branch, held in the St. Louis College of Pharmacy, December 18, 1914. The program of the evening was a most interesting one. Dr. H. M. Whelpley spoke on the subject, "Why The American Pharmaceutical Association?" Prof. Francis Hemm led in the discussion of Dr. Whelpley's paper, and stated that the bound volumes of the Association's yearly proceedings are the best reference books a pharmacist can own.

Dr. Leo Suppan gave an informal talk on "Historical Pharmacy of Missouri" and "The Missouri Pharmaceutical Association Exhibit at the Missouri Historical Society, Jefferson Memorial Building, St. Louis." He gave an interesting account of the early pharmacy of Missouri, and strongly urged the pharmacists of the state to take an active part in the collection of important historical material, relating to pharmacy.

JULIUS C. HOESTER, Secretary.

#### WASHINGTON, D. C.

The regular December meeting was held December 16, 1914, at 8:00 p. m., at the Institute for Industrial Research, Nineteenth and B streets, N; W., Washington, D. C.

The election of officers resulted in the following, all of whom were elected unanimously:—

President, Dr. H. E. Kalusowski; First Vice-President, Henry B. Floyd; Second Vice-President, Dr. W. W. Stockberger; Secretary, S. L. Hilton; Treasurer, W. S. Richardson; Chairmen:—Committee on Publicity, Dr. Lyman E. Kebler; Medical Relations, Frank C. Henry; Membership, Wyman H. Bradbury; Scientific Communication, H. C. Fuller; Legislation, G. W. Hurlburt.

After the disposition of the business before the meeting, President Richardson introduced Dr. C. D. Marsh, of the Department of Agriculture, who lectured on "Poison Plants Found on the Stock Ranches." His graphic descriptions of these plants and their ravages, illustrated by many lantern slides, some of

which were naturally colored, were exceedingly interesting, and an education almost in themselves. Most of his remarks were devoted to the *Cicuta*, or Water-hemlock, the Loco, and Larkspur. The effects of these poisons, and the rapidity of their action, were shown by a number of views of various cattle and sheep, taken but a few minutes apart.

The reading of Dr. William Salant's paper on "*Chenopodium*, (American Wormseed)", was postponed, because of the lateness of the hour, to a meeting in the near future.

Both Mr. Richardson and Dr. Marsh were given votes of thanks at the close of the meeting, the former for the unusually attractive programs he has secured the branch for the year, the latter for his most excellent and instructive entertainment.

Very truly yours,

HENRY B. FLOYD.

## Council Business

### COUNCIL LETTER NO. 10.

To the Members of the Council:—

The following Budget of Appropriations for 1915 is submitted by the Committee on Finance:—

#### PROPOSED BUDGET OF APPROPRIATIONS FOR 1915.

Appropriation.	
No. 1 Salaries .....	\$ 5500
No. 2 Journal .....	6600
(a) Publication .....	\$5000
(b) Clerical Expenses .....	900
(c) Postage and Stationery....	450
(d) Freight, Drayage and Miscellaneous .....	250
No. 3 Printing, Postage and Stationery .....	900
No. 4 Clerical Expenses Secretary's Office .....	416
No. 5 National Formulary .....	1000
No. 6 Miscellaneous Expenses .....	100
No. 7 Drayage, Freight and Expressage .....	100
No. 8 Stenographers .....	350
No. 9 Travelling Expenses .....	600
No. 10 Committee on Membership..	250
No. 11 Committee on Unofficial Standards .....	100

No. 25 National Syllabus Committee.	25

\$19,051

At the Detroit (1914) meeting of the Association, the Section on Pharmacopœias and Formularies was abolished, but there was created, as a sub-division of the Section on Practical Pharmacy and Dispensing a Committee on Pharmacopœias and Formularies.

Do you approve of Budget of Appropriations for 1915 as above proposed? This will be regarded as *Motion No. 19 (Approval of Budget of Appropriations for 1915.)*

J. W. ENGLAND,

Secretary of the Council.

<>

### COUNCIL LETTER NO. 11.

December 15, 1914.

To the Members of the Council:—

The following communication has been received:—

"Members of the Council, Gentlemen: It will be recalled that in Council Letter No. 2 (October 2, 1914), the subject of giving the Committee on Publication enlarged powers, etc. (as recommended at the Detroit (1914) meeting in President Beringer's address, approved by the Association and referred to the Council) was discussed, and under Motion No. 3, the Council authorized the Committee on Publication to effect a re-organization and to systematize its work.

Your Committee on Publication has been giving careful consideration to the subject and would report as follows:—

Article 11, Chapter V, of the by-laws of the Association relating to the Treasurer reads: "He shall pay no money except on the order of the General Secretary, accompanied by the proper voucher."

Rule Third of the General Rules of Finance, as adopted at the Detroit (1914) meeting reads:—

"The correctness of every bill shall be certified to by the person contracting the same and the General Secretary, and the latter

shall note on the bill the appropriation against which the same is to be charged. The bill shall then be submitted to the Chairman of the Finance Committee for approval before payment is made. A warrant shall then be drawn and signed by the General Secretary, upon receipt of which, together with the original bill and voucher, the Treasurer shall draw a check for the amount."

This rule superseded former Rule Third of the General Rules of Finance (Year Book, 1912, XXXII.)

It should be noted that both the by-law and rule are in full force and effect.

President Beringer recommended in his annual address that the Committee on Publication be given more extended power in the conduct of its work, and this recommendation was referred to the Council which authorized the Committee to effect a reorganization and to systematize its work, i. e. to organize a proper clerical and editorial staff so as to efficiently conduct the business of the Committee. It was suggested that to avoid the delay incident to the present method of paying the bills of the Association, the Committee's appropriation be paid to it quarterly, and that the Committee elect a Treasurer who should honor drafts made by the Editor and counter-signed by the Chairman and keep correct accounts of all receipts and expenditures on behalf of the Committee subject to the approval of the Council and Auditing Committee thereof.

But it is a serious question, in the light of Article 11, Chapter V, of the by-laws and Rule Third of the General Rules of Finance, as above quoted, whether we have the authority to pay bills other than through the General Secretary and Treasurer and as indicated.

The "by-law" was not amended at the Detroit meeting, and the "rule" was newly enacted, and both are in direct conflict with the plan proposed for the business of the Committee.

Fortunately, a careful study of the situation has indicated that it is not necessary to implement the plan of paying bills proposed, but that, with the formulation only of certain new "Rules of Publication," we can gain the end desired.

The advantages are to control the expenses of the Journal and publications of the Association, to secure the prompter payment of bills, more especially bills requiring immediate payment, such as those for postage, drayage, expressage, etc., and to relieve the

Editor from the necessity of advancing money from his own pocket to pay the bills of the Association.

To this end the following rules are recommended for adoption:—

#### GENERAL RULES OF PUBLICATION.

1. All bills on account of the Journal shall be certified to by the Editor and sent as soon as possible to the Chairman of the Committee on Publication for approval and then sent by the latter to the General Secretary for payment in accordance with Article 11, Chapter V, of the by-laws and Rule Third of the General Rules of Finance, except bills for postage, stationery, drayage, freight, expressage, miscellaneous and clerical expenses of the Office of the Journal (Petty and Clerical Expenses, Journal Office) which shall be paid as provided for in Rule 2 of these rules.

2. Bills for postage, stationery, drayage, freight, expressage, miscellaneous and clerical expenses of the office of the Journal (Petty and Clerical Expenses, Journal Office) shall be paid by check by the Editor of the Journal out of a deposit of \$300 to be made to the credit of the Editor of the Journal by the American Pharmaceutical Association in a bank to be approved by the Committee on Publication.

The Editor shall be bonded for \$500 at the expense of the Association.

The procedure for the payment of such bills shall be as follows:—(1) At the end of each month, the Editor shall send all paid-and-receipted bills and cancelled checks, with an itemized bill or statement, to the Chairman of the Committee on Publication for approval; (2) After approval, the Chairman of the Committee on Publication shall send the bills and checks to the General Secretary; (3) the General Secretary shall draw an order for the amount of the bills in accordance with Rule Third of the General Rules of Finance and forward the order and bills to the Treasurer; and (4) The Treasurer shall send the Editor a check to cover the amount of the bills and thus increase the bank balance.

3. All bills on account of the Year Book, National Formulary and other publications of the Association shall be certified to by the person contracting the same and approved by the Chairman of the Committee on Publication and sent by the latter to the General Secretary before payment in accordance with Article 11, Chapter V, of the by-laws and Rule Third of the General Rules of Finance.

The advantages of this method are many. It is simpler than having a Treasurer of the Committee through which to pay bills, and it does not require that one-fourth of the annual appropriation of each item of the work of the Committee shall be paid in

quarter to the Treasurer. The present machinery for the payment of bills is continued, the only change being the control to be given to the Chairman of the Committee on Publication in the payment of bills. In addition, the items of the annual budget of appropriations will not need to be changed.

Furthermore, the \$300 is practically advanced or loaned to the Editor under bond and the bills are really not finally paid by the Association until the Treasurer sends the check each month to cover the amount of vouchers paid, so that the Association is protected in every way.

The above proposed "Rules of Publication" were submitted to Julius A. Koch, Chairman of the Finance Committee, and he heartily endorses them.

In this connection, General Secretary Day writes as follows:—

"I have Letter No. 8 of the Committee on Publication. I like the plan of placing a fund of \$300 in the hands of the Editor from which he is to make by check such disbursements as may be necessary to cover the small expenses of his office. This amounts practically to establishing in the Editor's office a petty expense fund.

"As Actuary of the School of Pharmacy I have for years had such a petty expense fund. You may be interested in knowing how I manage this fund. The amount deposited with me by the University for this fund was \$250. I placed this amount in my bank subject to check but separate from my personal checking account. I draw the checks from the petty expense fund as W. B. Day, Actuary. At the end of each month I report to the business office of the University the condition of the fund and turn in a bill for the expenditures of the month with the receipts for the individual items of expense attached thereto. A duplicate of this bill is retained for my files. The University check for the amount of this bill is sent to me in due time, thus restoring original amount of the fund. My cancelled checks are my personal receipts for the expenditures from this fund and are retained in my office. I am thus able at a moment's notice to give a statement of the condition of this petty expense fund and to make a complete accounting therefor. I think some such plan might be followed if the proposed petty expense fund for the Editor's office is decided upon. You may record me as being in favor of this plan."

The Committee on Publication submits the above "Rules of Publication" for your consideration and asks that they be approved.

Very truly yours,

J. W. ENGLAND,

Chairman of Committee on Publication."

Further communications have been received relative to *Motion No. 17* (C. L. No. 7), as follows:—

John B. Thomas writes:—

"Replying to A. Ph. A. Council Letter No. 9, it seems to me that it would be best to table *Motion No. 17* right now.

"Although I voted to extend the invitation and would have heartily welcomed the acceptance of the same, I fear that further discussion of this motion might be resented and result in a lack of harmony in our own ranks.

"In my opinion, we cannot afford to entertain this subject at this time."

Thomas D. McElhenie writes:—

"Relating to the matter of invitation to the Japanese Pharmaceutical Association, I think if there is yet time I will ask leave to reverse my vote to the negative. It seems to me very likely that Dr. Schneider was actuated probably by a feeling of good fellowship coupled with the natural enthusiasm of a local Secretary to make his meeting a notable success, and as a well-known scientist he very likely has friends and correspondents in Japan and probably throughout the world and may be familiar with the Japanese language, but did not think of the long, long way from Tokio to Frisco. I scarcely think that the Japanese Society would take the matter seriously. They could not possibly muster enough of their members in San Francisco to hold a regular meeting of their own body and they could not understand the proceeding of our meeting except by the use of interpreters, which would be burdensome and tedious. Besides, there is the duty of host for our Association to the visitors and no fund available for such use.

"If there is a national body of pharmacists in Mexico or Central America they might like to meet in Frisco, but the same difficulty of language would prevail."

L. E. Sayre writes:—

"In response to your request that there be an expression of opinion in regard to the invitation to the Pharmaceutical Society of Japan, I would say that, after reading the communications contained in Letter No. 9 and previous communications, I am impelled to change my vote from the affirmative to negative.

"I am inclined to think, however, that it would be better to reconsider the former motion. I would be glad to make this motion or second the motion that any other one should make, asking for a reconsideration.

"I am sorry, however, that this reversal of the vote, in view of what has already been done, puts us in a rather embarrassing position, but through no fault of the Council."

By "former motion," Professor Sayre probably refers to *Motion No. 12* (C. L. No.

6) on invitation to Canadian Pharmaceutical Association, which motion, while it received a majority of affirmative votes, can readily be reconsidered, if desired, as no notice of action has yet been sent to the Canadian Pharmaceutical Association.

Frank H. Freericks writes:—

"With reference to Motion No. 17, and your request for an expression, I would point out that I voted against extending an invitation to the Society of Japan, as also against extending such invitation to the Canadian Society. My reason for voting against such invitation was primarily based on the fact that when I as an individual extend an invitation, I mean to, and hope to have it accepted. Personally, I could not wish for the acceptance of our invitation by either Society, because it would only tend to further interfere with our own work at the San Francisco Convention, thus resulting to the disadvantage of our Association. It is this feature which controlled me entirely in voting No. on both Motions, however, I do not want to dismiss the subject without saying, that a spirit of neutrality owing to the War was also in my mind. People who are directly concerned in the War, are apt to have very strong and possible prejudiced opinions. It is altogether likely if the Canadian or Japanese Society should meet with us, that there would be at least an expression of personal opinion. Taking it for granted that such expression would be in keeping with the opinion which seems to prevail in Canada and no doubt in Japan, I personally would find it very difficult to avoid expressing a different opinion, for after all, speaking for myself I am only human, and have very strong convictions regarding the War which would be I am sure unpleasant for either men from Canada or Japan to hear. However, as stated, my vote was controlled primarily by the belief that such invitation if accepted would only add to our difficulties which of themselves are plenty in an Exposition City."

*Motion No. 20 (Tabling of Motion No. 17)* Moved by J. B. Thomas, seconded by C. A. Mayo, that *Motion No. 17 (Extension of Invitation to Pharmaceutical Society of Japan to meet in San Francisco in 1915)* be tabled.

*Motion No. 21 (Applications for Membership)* You are requested to vote on the following applications for membership:

No. 52. Leonard Ellsworth Coolbaugh, In care McKimsey's Pharmacy, Corsicana, Texas, rec. by Freeman P. Stroup and E. Fullerton Cook.

No. 53. Harry S. Harrison, 447 S. Clinton St., Baltimore, Md., rec. by H. A. B. Dunning and J. W. Westcott.

No. 54. Mrs. Anna L. Wiley, Hartville, Ohio, rec. by Anna G. Bagley and George B. Kauffman.

No. 55. Elmer A. Watson, Clayton, Ill., rec. by H. M. Whelpley and J. W. Mackelden.

No. 56. Jose Antonio Gonzalez Jones, P. O. Box 166, Barranquilla, Columbia, S. A., rec. by H. M. Whelpley and J. W. Mackelden.

No. 57. Mansfield B. Herald, 1027 Story St., Boone, Iowa, rec. by Zada M. Cooper and Wilber J. Teeters.

No. 58. Eduardo Garcia Faundo, Monte 497, Havana, Cuba, rec. by Jose P. Alacan and Jose Guillermo Diaz.

J. W. ENGLAND,  
Secretary of the Council.

#### COUNCIL LETTER NO. 12.

December 26, 1914.

To the Members of the Council:—

*Motions No. 19 (Approval of Budget of Appropriations for 1915), No. 20 (Tabling of Motion No. 17), No. 21 (Applications for Membership; Nos. 52 to 58 inclusive)* have each received a majority of affirmative votes.

The following communication (December 17) has been received from J. A. Koch, Chairman of the Finance Committee:—

"I believe that in order to avoid any chances of mis-interpretation, paragraph 3, of Section 2, General Rules of Publication, page 35, Council Letter 11, should read:

"The procedure for the payment of such bills shall be as follows: (1) At the end of each month, the Editor shall send all paid-and-receipted bills and cancelled checks, with an itemized bill or statement, to the Chairman of the Committee on Publication for approval; (2) After approval, the Chairman of the Committee on Publication shall send the bills and checks to the General Secretary for payment in accordance with Article 2, Chapter 5, of the by laws and Rule Third of the General Rules of Finance; and (3) The Treasurer shall send the Editor a check to cover the amount of the bills and thus increase the bank balance."

The change proposed involves no change in the intent of the rule, but simply clarifies its meaning. If there is no objection, the new paragraph will be substituted for the original paragraph.

The Detroit Branch, A. Ph. A. was organized on December 11, 1914. The following officers were elected: President, W. A. Hall; Vice-President, A. A. Wheeler; Secretary, Willbur L. Seville; Treasurer, C. F.

Mann; Council Representative, Leonard A. Seltzer.

At the meeting of the City of Washington Branch, A. Ph. A., held December 16, 1914, Samuel L. Hilton, 22nd and L Streets, N. W., Washington, D. C., was elected representative to the Council from the Branch for the years 1915, 1916 and 1917, succeeding Henry B. Floyd.

The following letter (December 15) has been received from Albert Schneider:—

"I am very much afraid that some of our good friends are making much ado about nothing. It strikes me that extending the invitations to our brothers across the sea is but a kindness which, so it appears to me, we owe them merely as a matter of special consideration and courtesy occasioned by the great San Francisco Exposition. You may rest assured that the Exposition Management are heartily in accord with us in the matter. We do not obligate ourselves further than to show our visitors such consideration and kindness as we are in position to offer. We are in no wise obligated financially. The Exposition Management will gladly grant meeting-hall privileges and the local druggists would no doubt join us in showing them some courtesy.

"I desire to state further, as prime mover in extending the invitation, that the motive was wholly neutral and impartial. In other words, the invitations were purely intellectual, based upon the consanguinity of common scientific interests, and entirely apart from any personal opinions and feelings regarding nationalities."

The following letter (December 23) has been received from F. T. Gordon:

"I have given a good deal of thought to the matter of inviting the Pharmaceutical Society of Japan to hold joint sessions with us at our San Francisco meeting and I am afraid that we have unwittingly stirred up the depths of international feelings. I lived in Japan for three years and know what a proud and sensitive people they are and that they keenly resent any patronage of superiority from us or any other nationality. I fear the matter has gone too far now, for copies of our Journal are doubtless in their hands by this time and our comments must cut deeply to the quick when read by the educated Japanese. The whole matter was a blunder, well meant as are all blunders, but hard on the victim. What the Association should have done, in my opinion, was to recognize no nation, no class, no creed, but that of pharmacists working for the welfare of all mankind to alleviate suffering and to make better men of those entrusted to our care. When the world is torn by war we are all brothers, not fighters.

Therefore, I make the following motion: That the American Pharmaceutical Association send, individually and collectively, its sincere appreciation of the unselfish work done by brother pharmacists of all nations in relieving the sufferings of war and of the sacrifices made, and that as Americans of every national descent we honor them and pray for their welfare and future peaceful prosperity. Also:—

That copies of this motion be sent to the appropriate officers of the pharmaceutical associations of the various nations as an expression of the sympathy and good will of their brother pharmacists in the United States and as a New Year's greeting, a new year of peace and prosperity for all. Also:—

That the President of the American Pharmaceutical Association be empowered to have suitable forms or letters made that will express this sentiment and forward them under his official title through the Secretary of the American Pharmaceutical Association."

Mr. Gordon's motion is seconded by J. W. England. Do you favor it? It will be regarded as *Motion No. 22 (Greetings to Pharmacists and Pharmaceutical Associations of other Nations.)*

*Motion No. 23 (Approval of General Rules of Publication.)* Moved by C. A. Mayo, seconded by Dr. F. E. Stewart, that the General Rules of Publication as set forth in Council Letter No. 11 be approved.

*Motion No. 24 (Election of Local Secretary for 1915.)* Moved by Dr. F. E. Stewart, seconded by F. T. Gordon, that Albert Schneider of San Francisco, be made local Secretary for 1915.

No action has been taken by the Council on the question of the proposed A. Ph. A. Exhibit at the Panama Pacific Exposition, and to dispose of the question, William R. White writes as follows:—

"In regard to the discussion of the question of the A. Ph. A. having an exhibit at the Exposition, will say that I think we are not able to finance such an undertaking and in view of the uncertainty of getting the assistance necessary from other sources, and in order to settle this question before the Council, I move that the Council disapprove of the effort being made to have an exhibit at the San Francisco Exposition."

The above motion is seconded by George M. Beringer, and will be regarded as *Motion No. 25 (Disapproval of Proposed Exhibit at the Panama-Pacific Exposition.)*

J. W. ENGLAND,  
Secretary of the Council.

## The Pharmacist and the Law

### LIABILITY FOR BOTTLE EXPLOSION. PRIVITY OF CONTRACT.

In an action for injuries caused by the bursting of a soda-pop bottle, the defendants were engaged in manufacturing and selling soda-pop, and the plaintiff and her husband sold soft drinks. They bought from the defendants a case of their goods, and, after it was delivered, the plaintiff lifted one of the bottles from the case and was carrying it to the ice box when the bottle exploded, so injuring her eye that it had to be removed. The trial court directed a verdict for the defendants. On appeal it was held that there was sufficient privity between the plaintiff and the defendants for her to maintain an action for her injuries, though she was not a partner with her husband, and was merely acting under his direction. If, it was said, the vendor is to be held liable at all for his negligence in cases of this character, there is no reason for limiting that liability in favor of the vendee individually, who may never personally be exposed to the danger resulting from this negligence.

Actionable negligence, has been defined as a breach of duty resulting in injury to some person to whom that duty is legally owing, and the duty here was not merely to so charge a bottle as that its contents might not be wasted, but also to exercise that care which an ordinarily prudent person would use, to avoid the infliction of an injury which might reasonably be expected to follow the failure to use this care; and that duty was owing, not only to the vendee, but also to his employer, who performed the service which the parties must have contemplated as necessary to be performed when the sale was made.

The court cited the case of *O'Neill v. James*, 138 Mich. 367, 101, N. W. 828, 68 L. R. A. 342, 110 Am. St. Rep. 321, 5 Ann. Cas. 177, as one where the facts are strikingly similar to the facts in the present case, except that the party injured by the explosion of the bottle was an employee of the owner of the business, and there was no proof of knowledge upon the part of the defendant that the bottle which exploded had been im-

properly charged with the gas. In that case the plaintiff has recovered a substantial judgment, which was reversed on appeal because of the insufficiency of the evidence to sustain the allegations of the complaint. It was held that a manufacturer of champagne cider, which is ordinarily not dangerous, is a common article of commerce, and is manufactured by him by proper machinery, and not excessively charged, is not liable for injuries to an employee of his customer through the explosion of a bottle, unless he knows that for some reason such bottle is peculiarly liable to explode. The court distinguished that case from the present, because there was proof in the latter, tending to show that the bottle was improperly charged, and that the defendants were aware of that fact, or were at least in possession of such knowledge and information on that subject as would impute knowledge to them of that fact. The ordinary law of principal and agent would charge the defendants with any knowledge possessed by their employees who were actually engaged in charging the bottles.

The evidence presented no issue for submission to the jury upon the question of the use of defective bottles, as the proof showed the bottles were purchased from a manufacturer whose bottles were of standard grade and quality, and the only theory upon which a recovery could be sustained, was that the defendants were guilty of negligence in charging the bottle, and that this negligence was the proximate cause of the injury. On the ground that the latter issue should have been submitted to the jury, the judgment for the defendants was reversed.

*Colyar v. Little Rock Bottling Works.*

Arkansas Supreme Court, 100 S. W. 810.

### IMPLIED WARRANTY OF FITNESS FOR PURPOSE KNOWLEDGE OF BUYER.

In an action for the purchase-price of a secret chemical preparation known as "dynamite" for killing grass and weeds, the defense was an implied warranty that one application was sufficient, whereas two applications were required. It was held that where a manufacturer sells an article for a particular purpose, so that the buyer necessarily trusts to his judgment, the law implies a promise that the article is reasonable, fit and proper for such purpose; but such implied

promise is conditioned and dependent upon the use of the article in the manner, quantity, and under the conditions prescribed by the manufacturer, and, when not so used, then such promise is not implied. It appeared that the defendant railway company's general manager had been informed before the contract was made that the seller claimed that two applications were necessary. It was held that there was no implied warranty that one application would suffice, and the fact that the defendant's other representatives, those to whose judgment and discretion the purchase of the "dinamine" was committed, did not have this information imparted to them by the general manager did not alter the situation. Evidence, therefore, that such representatives were not so informed, and would not have made the purchase had they known that two applications were necessary, was not material. Judgment for the plaintiff was affirmed.

Missouri, K. & T. Ry. Co. of Texas v. Interstate Chemical Co., Texas Civil Appeals, 169 S. W. 1120.

### Changes of Address

All changes of address of members should be sent to the General Secretary promptly.

The Association will not be responsible for non-delivery of the Annual Volume or Year Book, or of the JOURNAL, unless notice of change of address is received before shipment or mailing.

Both the old and the new address should be given, thus:

HENRY MILTON,  
From 2342 Albion Place, St. Louis, Mo.  
To 278 Dartmouth St., Boston, Mass.

Titles or degrees to be used in publications or in the official records should be given, and names should be *plainly* written, or type-written.

G. H. GOGSEY,  
From Camp John Hay, Benguet, P. I.,  
To Sgt. 1st Cl. H. C. Post Hosp., Ft Meade, So. Dak.

H. C. NEWTON,  
From Southboro, Mass.,  
To care Creighton College of Pharmacy  
Omaha, Neb.

H. G. POSEY,  
From Peniston St., New Orleans, La.,  
To Cor. Hurst & Webster Sts., New  
Orleans, La.

MRS. FANNIE SCHENK,  
From Deer Trail, Colo.,  
To 1321 Broadway, Denver, Colo.

W. D. BOST,  
From 6015 a Hortay Pl., St. Louis, Mo.,  
To 50-60 First St., San Francisco, Cal.

J. D. GLANCY,  
From West Upton, Mass.,  
To 59 Gates Ave., Brooklyn, N. Y.

C. C. YOUNG,  
From 735 Church St., Nashville, Tenn.,  
To Residence unknown.

CHAS. A. BILLUPS,  
From Jefferson Barracks, Mo.,  
To Residence unknown.

J. C. LIEBER,  
From Houston, Texas,  
To Fort Sam Houston, Texas.

C. M. DODSON,  
From 418 So. Washington, Enid, Okla.,  
To Residence unknown.

K. C. ROBBINS,  
From Ft. Worth, Texas,  
To Station A, No. 215 North Lancaster  
St., Dallas, Texas.

J. L. GERLACH,  
From Ft. Terry, N. Y.,  
To With U. S. Forces, Vera Cruz, Mexico

DAVID GOODMAN,  
From Ft. Mills, Corrigedor, P. I.,  
To Manila R. R. Co., Manila, P. I.

M. E. BELSON,  
From Lott, Texas,  
To Rosebud, Texas.

WM. H. LAMONT,  
From Chicago, Ill.,  
To 1205 Clara Ave., St. Louis, Mo.

EDWARD HOFFMAN,  
From 4924 Fifth Ave., Brooklyn, N. Y.,  
To 4422 Sixth Ave., Brooklyn, N. Y.

F. B. POWER,  
From London, England,  
To 535 Warren St., Hudson, N. Y.

E. H. HESSLER,  
From 145 No. 10th St., Philadelphia, Pa.,  
To 309 So. 12th St., Philadelphia, Pa.

L. S. BRIGHAM,  
From 1 Gordon St., Savannah, Ga.,  
To 20 East Henry St., Savannah, Ga.

G. S. LOHMAN,  
From St. Louis, Mo.,  
To 2043 Alice Pl., St. Louis, Mo., care  
Johnson Bros.

JOHN BEST,  
From 1 German Block, Central City, Colo.,  
To Residence unknown.

J. K. MEHRTEHS,  
From 5251 11th Ave., San Francisco, Cal.,  
To Food & Drug State Laboratory,  
Berkeley, Cal.

- CARL G. ANDERSON,  
From 2016 Cleveland Ave., Chicago, Ill.,  
To 901 Wells St., Chicago, Ill.
- H. A. R. KROGER,  
From Camp Downes, Manila, P. I.  
To Residence unknown.
- MAX RISENBERG,  
From Camp Connell, Samar, P. I.  
To Walter Reed General Hospital, Tacoma  
Park, D. C.
- HARRY COOK,  
From Petit Barracks, Zamboango, Min-  
danao, P. I.  
To Residence unknown.
- M. J. NOLL,  
From 5571 Vernon Ave., St. Louis, Mo.  
To 11 So. Fourth St., care Eli Lilly, St.  
Louis, Mo.
- CHAS. H. ROGERS,  
From care Pharm. Dept., Univ. of Minn.,  
Minneapolis, Minn.  
To W. Va. Univ., Morgantown, W. Va.
- JEANNOT HOSTMANN,  
From 1122 Hudson St., Hoboken, N. J.  
To 1208 Hudson St., Hoboken, N. J.
- HOWARD W. GARDNER,  
From 517 Monroe St., Brooklyn N. Y.  
To 1547 Capouse Ave., Scranton, Pa.
- M. K. BERKOWITZ,  
From U. S. Marine Hosp., Cairo, Ill.  
To U. S. Quarantine Station, Pensacola,  
Fla.
- C. V. NICHOLS,  
From 408 East Main St., Anadarko, Okla.  
To 1005 Lincoln Ave., Ann Arbor, Mich.
- JUSTIN S. BREWER,  
From 2532 Third Ave. S., Minneapolis,  
Minn.  
To 2113-29 Franklin Ave., St. Louis Mo.
- DECEASED SINCE OCT. 18, 1914.

mazoo, Mich.

## OIL OF PEPPERMINT.

Weather conditions during the early spring and throughout the summer were extremely favorable, and a thorough canvass made by our representative in producing districts early in June showed an increase of over 3,000 acres over the acreage of 1913.

Throughout the season the peppermint plants looked very promising, and the distilling was begun as early as the latter part of June, which is quite unusual. It furthermore developed that the yield was exceptionally large and averaged at least 30 pounds of oil per acre, generally more, and, in consequence, a production of between 550,000 and 600,000 pounds of oil has to be reckoned with this year, while the annual consumption is estimated to amount to about one-half of this quantity.

Stocks of old oil were nearly exhausted before the new crop could be marketed, and during the months of May and June the high price of \$4.25 per lb. was reached. As soon as the new oil was available a rapid decline took place, until the present values prevailed.

The export demand, on account of the European war, being very small only, and, on account of business conditions in general, it would not be surprising if the declining tendency which has so far prevailed would continue, and unless next year's crop should prove to be an entire failure, it is reasonable to assume that peppermint oil may be bought at moderate figures for some time to come.

Since the high prices which prevailed during the last few years enabled the farmers to take better care of their fields, the quality of this year's oil was generally found to be excellent. *From Advance Circular, Fritzsche Brothers.*

## Section on Practical Pharmacy and Dispensing

Papers Presented at the Sixty-Second Annual Convention

### MINUTES OF SECTION

The Third Session of the Section was held on Thursday, August 27, on the boat while on the trip to St. Clair Flats.

Chairman Nitardy presided over the meeting and, as the first order of business, called for a discussion on Mr. Hall's paper on "A New Antidote for Corrosive Sublimate Poisoning," read at the previous session. [Printed in this issue.]

On motion of Mr. Raubenheimer, the paper was referred to the Scientific Section for study, pharmacologically, and the Secretary was instructed to forward the paper to that Section.

Mr. Jeannot Hostmann read a paper entitled, "Assaying Galenicals." [Printed in this issue.] This paper was briefly discussed by Messrs. Mansfield, Nitardy, Weinstein, Hynson, Raubenheimer and Hostmann, opinions being expressed that the cost of the equipment needed by a retail pharmacist was but slight and that such equipment was an extremely valuable addition to any store, Mr. Weinstein expressing the opinion that a microscope was a more essential agent for better work in a drug-store than is a cash-register.

Chairman Nitardy read a paper on "The Preparation of Flake Agar-Agar." [Printed in this issue.] In commenting upon this paper, Mr. Raubenheimer suggested cutting the agar-agar up with scissors, and Mr. Apple stated that he had found a tobacco-cutter useful in such work.

The next business considered was the pharmaceutical questions proposed by Chairman Nitardy, as follows:—

Question 1:—Creosote..... one drachm  
Syrup Hypophosphites Compound..... eight ounces  
Cod Liver Oil..... eight ounces  
Mix.

How would you dispense this, and why?

#### DISCUSSION.

Prof. Otto RACHENBERGER: "This prescription will necessarily be a 'shake mixture' and should be dispensed with a 'Shake Well' label. The creosote might be dissolved in the oil and then the syrup added gradually with constant shaking. A still better way would be to emulsify the creosote by means of powdered acacia and water, then to add the oil gradually with constant agitation and finally the syrup. The latter method is undoubtedly the more pharmaceutically correct."

Mr. GRAY: "I would mix the creosote with the oil and then add the syrup, using a bottle large enough to admit of a vigorous shaking on account of the oil and syrup not being miscible. I would dispense the preparation with a 'Shake Label.' Preferably, I would dispense the solution of the creosote in the oil in one bottle and the syrup in another, mixing the two preparations at the time of administration."

Mr. SCHUTZ: "I would dispense this prescription in the form of an emulsion made by using powdered acacia and water, then thoroughly incorporating the oil in that way with the other ingredients and making a more sightly and palatable preparation."

Mr. FRID: "I would mix the creosote with the oil and emulsify. Then add the Syrup Hypophosphites Compound."

Prof. LYSONG: "There are several ways of preparing this prescription, but the one approved by me is to emulsify the creosote and the syrup with two and one-half drachms of powdered acacia, adding the oil in small portions until a uniform mixture results. I put this mixture aside for about ten days, and no separation occurred. In all other instances it formed a heavy thick mixture which could not be dispensed in an ordinary bottle."

Mr. SYSS: "I would dispense it just as it is written but would attach a 'Shake Label.'"

Mr. ARTER: "I think the physician should be consulted before adding any emulsifying ingredients. I would dispense such a prescription just as it is written with the caution to 'Shake Well' before administration."

Question 2: What do you think of using a specially shaped bottle for dispensing poisonous or dangerous preparations? Where would you draw the line as to what and what should not be dispensed in these kind of bottles?

#### DISCUSSION.

Mr. GRAY: "I think it is a very good idea, and I have used them for many years. I will give you a list of some of the preparations which I have used in these bottles."

Mr. GRAY: "I have used them for many years. I will give you a list of some of the preparations which I have used in these bottles."

Prof. RACHENBERGER: "I have used them for many years. I will give you a list of some of the preparations which I have used in these bottles."

Mr. GRAY: "I have used them for many years. I will give you a list of some of the preparations which I have used in these bottles."

Prof. RACHENBERGER: "I have used them for many years. I will give you a list of some of the preparations which I have used in these bottles."

Mr. GRAY: "I have used them for many years. I will give you a list of some of the preparations which I have used in these bottles."

Mr. SCHUTZ: "I have used them for many years. I will give you a list of some of the preparations which I have used in these bottles."

we have performed our duty. Carelessness, neglect to observe directions of labels, and suicide we can only partially guard against."

MR. FERTÉ:—"A colored bottle with a distinctive shape is desirable to be used if there is an understanding in relation to them. Medicines which in teaspoonful doses would be fatal should be dispensed in such bottles."

PROF. LASCOFF:—"Owing to the fact that many errors are made by persons taking, internally, medicines which were intended for external use, all bottles containing dangerously poisonous substances should be dark-colored and, preferably, of a triangular shape, to distinguish them from those containing medicines intended for external use."

MR. GRAY:—"A bottle with diamond-points, with a stopper of corresponding shape, is an excellent one to use in a limited degree, say for carbolie, nitric, hydrochloric, sulphuric, glacial acetic, hydrocyanic and nitro-hydrochloric acids, stronger ammonia water and formaldehyde, and for such preparations as Liquor Cresolis Compound, Wine of Colchicum, Fowler's, Pearson's and Donovan's Solutions and for potent tablets: also for fluid extracts of aconite, belladonna, digitalis, cannabis indica, adonis vernalis, gelsemium, hyoscyamus, nux vomica, opium, physostigma veratrum and strophanthus. These with the addition of oxalic acid, tartar emetic, paris green, corrosive sublimate, sugar of lead, potassium ferro- and ferri-cyanid, and potassium dichromate about covers the field. In my opinion the general use of the poison-label has a tendency to cause a disregard of the same."

Question 3:—What is the best container for dispensing ointments on prescriptions?

#### A PLEA FOR REFORM IN THE DISPENSING OF OINTMENTS AND SIMILAR PREPARATIONS.

F. W. NITARDY, PH. C.

In such common use are ordinary glass ointment-jars and metal boxes as containers for ointments and similar soft preparations, that their unclean and insanitary feature fails to impress us without special attention being called thereto.

Ointments, etc., are used as an application to skin, mucous membranes or exposed surfaces. These are frequently infectious, and by the usual mode of application the medicament must necessarily become contaminated. It is not an uncommon occurrence that several people, or various members of a family, will use an ointment, each, in their turn, dipping into it with fingers infected by the disease for the alleviation of which it is applied.

Aside from the dangers of contamination with pathogenic bacteria, the imperfect seal, as well as carelessness on the part of the consumer, frequently causes the preparation to become unsightly, altered or spoiled by oxidation, evaporation and other effects of exposure to atmosphere, light and dust.

Economically, these containers are wasteful as the last portions of their contents must frequently be thrown away. Even from a stand-point of convenience we can hardly find an argument in support of their use.

The collapsible-tube is free from these objections and serves as a container, protecting its contents from every form of contamination or exposure. It is easily filled and more convenient for the patient. Properly dispensed, it makes a neater and more attractive package. Its additional cost is trifling, compared to its advantages, and this can easily be added to the customary charge without causing complaint on part of the customer.

For prescription-use it is preferable to have lacquered pure tin tubes in assorted colors that fit into hinged boxes lined in corresponding colors. In this

way two or more tubes of ointments of the same size may be prescribed for one patient without danger of confusion. The number, doctor's name and directions are placed on the box. If desired, the tube may also be numbered, either before filling, with a steel numbering machine, such as is usually used for prescriptions; or after filling, with an ordinary lead pencil. In the former case it is best to have a cylindrical hardwood block with a flattened place on which a piece of cardboard is pasted to act as a cushion; the block should just fit the tube; the number may then be indelibly impressed into the soft metal of the tube. In the latter case it will be found that the marks produced on a filled tube with a bluntly-pointed pencil, knitting needle or similar blunt instrument, are sufficiently deep impressions to remain readable even after the tube is emptied and rolled or crumpled up. Such numbers on the tube are, of course, preferably placed near the shouldered end. Covered metal clips, capable of being numbered, may also be placed over the folded end.

The filling of individual tubes is most easily accomplished by rolling the preparation into cylindrical form with a piece of paper, slipping this into the tube, flattening the paper cylinder just beyond the portion holding the ointment and then withdrawing the paper, continuing to flatten it as it is being withdrawn, so as to force the ointment out of the paper into the tube. After one trial the operation will be found just as quick and simple as filling a jar with a spatula.

When tubes are used for such preparations such as should not come in contact with metals, the tube must, of course, be previously coated with a suitable lacquer. Collodion or an ethereal tincture of tolu, are suitable for this purpose. A little of this is poured into the tube and rotated so as to completely cover the inner surface, the surplus is then poured out and the tube allowed to dry. The operation takes only a few minutes.

Pure materials, care and cleanliness in compounding are put to naught if we choose containers incapable of properly preserving our products under the ordinary conditions to which they will be subjected after leaving our hands. This applies not only to ointments but to all preparations or products dispensed.

We should put forth constant effort to make each package leaving our prescription-department as neat, convenient and perfect as possible. We should never allow a package to go out that is incapable of keeping its contents in the desired condition, for carelessness in these things cannot help but reflect carelessness on the rest of our work.

#### DISCUSSION.

Prof. RALPH MERRILL: "Although the ointment jar, usually the jar of glass, has a strong hold on the pharmacist as well as with the public in the United States, it is only a question of time when collapsible tubes will come into general use for dispensing ointments, especially for those dispensed on prescriptions. It is my experience that their popularity among physicians is increasing. Their use is a sanitary method for dispensing ointments and they are also economical to use. What a contrast between the unsanitary earthen ointment jar and the sanitary collapsible tube of today."

MR. NICHOLS: "I would like to make the matter better known by showing some boxes and tubes along to illustrate my meaning. The ointment is dispensed in a colored tube and the color of the box and tube are alike. In the lid of the box we have reading-matter that tells to the doctor as well as to the patient the object of dispensing ointments this way. The lid reads: 'Cleanliness and purity are of prime importance in all medicines. We have therefore, devised this package which will protect the contents from any contamination until

all is used, an end not easily accomplished when drugs of this nature are dispensed in the old style, in an unsanitary jar or box."

MR. JONES:—"What method do you use to fill the tubes?"

MR. NITARDY:—"It is a little hard to make that clear in a paper. Where there is many to fill it is best to use a machine. In the absence of a machine, place the ointment upon paper, roll it up small enough to slip into the tube, then pinch the paper and draw it out leaving the ointment in the tube."

MR. JONES:—"I have always used that method, but I thought there might be some better way. What do you charge for that extra service?"

MR. NITARDY:—"I cannot answer that question. I am not directly connected with the prescription-department. I have charge of the laboratory. I suggested this system to our prescription-department and I asked them to add a charge of five cents for the smaller and ten on the larger tubes. This package costs us complete for the smaller size about four and a half cents, and the larger ones about nine and a half."

MR. REYER:—"Would it not be possible to leave the paper inside the tube? It would protect the ointment from contact with the sides."

MR. NITARDY:—"It would do no harm. There would be no objection, except that the paper might be forced up and interfere with the emission of the ointment."

MR. RAUBENHEIMER:—"The older members can well remember the earthen-ware ointment jars, a very unsanitary container. From these we passed to glass, which with the aluminum tops were a great improvement. The collapsible tubes are however the real thing, more sanitary. Besides the sanitation they are really more economical, because the patient only has to take from the tube the amount only that he requires. The manner in which this is prepared by Mr. Nitardy seems to me to be rather an extravagant way however. As he puts it up I would charge fifty cents for it, whether a dram or an ounce. Do you place labels on the tubes?"

MR. NITARDY:—"It is a difficult thing to retain a label on an ointment-tube. We found that we could number the tube itself and that is what we are now doing. The box also is numbered so that the package-number and the box-number agree. We call attention to the need of always keeping the tube in its own box also by a label attached."

MR. APPLE:—"It occurs to me, that from a legal stand-point it would be advisable to label the tube. If you should be haled into court you could prove that you had taken that precaution against mistake."

MR. MAYO:—"In New York we have a law that requires the labelling of prescriptions in a certain prescribed way. It is doubtful if the courts would construe the application of a number as a compliance with the law."

MR. MYERS:—"As to the labelling of tubes or anything made of tin, I use a little banana oil, instead of tinct. of benzoin. The label then adheres very strongly to the tin."

MR. NITARDY:—"Collapsible tubes are very much the best for dispensing ointments. They are not more expensive than other containers, unless the tube is dispensed in another container."

MR. SCHULZE:—"It has been our experience that our trade, at least, prefers the screw-cap ointment-jar to the collapsible tube."

MR. FERTÉ:—"The best container for ointments is the collapsible tube. If the medicament of the ointment is one that will attack the metal of the tube it is well to fill the tube with tincture of benzoin, or some suitable lacquer, then drain them and dry."

PROF. LASCOFF:—"Collapsible tubes, in my opinion, are the best to use for the dispensing of ointments. They are cleaner than any other containers, can be readily made sterile; only a small amount of the ointment is exposed to air and thus rancidity is prevented, and when they are once emptied they are never re-filled."

MR. GRAY:—"I prefer an opalescent jar with an aluminum top. They look neater and therefore make the best impression on the patient."

Question 4:—Does the ordinary shop label, as supplied by most label-houses, give intelligent directions for use, proper and available antidotes in case of poisons and such other information as is desirable? Are abbreviations desirable? Do you consider a bottle of Spirit of Camphor, put out under a label reading "Spts. Camphor," any reflection on the pharmacist's knowledge?

#### DISCUSSION.

MR. APPLE:—"It is certainly advisable that "Poison Labels" should be printed in red ink and should have the antidote printed upon them, also a skull and cross-bones."

MR. GODDING:—"The State of Massachusetts requires all poison labels to be printed in red ink."

MR. NITARDY:—"I have found it very necessary to carefully observe the antidotes stated on labels by label-houses."

MR. GRAY:—"Store labels are improved by adding the dose, use and, in case of poisons, the antidote for same to the labels."

PROF. LASCOFF:—"I would suggest that the labels which are put on preparations of a poisonous nature should be carefully reviewed by pharmacists before accepting them from the printer, as one cannot be too careful in such matters. No abbreviations should be allowed on any labels. All names should be printed in full. For preparations intended for external use, it would be advisable to use a red label, on which is printed the words, 'For External Use.' For instance, Salt of Tartar is frequently confounded with Cream of Tartar, but if the former is labeled in red and marked 'For External Use' no misunderstanding will occur."

MR. FERTÉ:—"To the first question I would answer 'No' and to the second one I would reply that it is unfortunate that so many of our profession do not differentiate between the singular and the plural. It would be as proper to label a bottle Tinctures Arnica, or a jar Zinc Ointments. Such ignorance is a disgrace. It is also inexcusable to write either carelessly or ignorantly of 'bromide of soda' or of 'permanganate of potash.'"

PROF. RAUBENHEIMER:—"The ordinary labels supplied by printing-houses need very careful supervision, especially as to directions for use and antidotes for poisons. Such labels as 'Rochelle Salts,' 'Spirits of Camphor,' are good illustrations as to the little care printers use in wording the labels. It is very desirable that the nomenclature of the U. S. P. and the N. F. should be used. The correct wording of a label may appear trilling, but, in my opinion it carries much weight with the intelligent public."

Question 5:—How would you advertise your prescription department?

#### HOW WOULD YOU ADVERTISE YOUR PRESCRIPTION DEPARTMENT?

---

JACOB DINER, PH. G.

---

Theoretically a prescription department should require no advertising. Just as all men are supposed to be equal before the Law in this greatest of all countries, but are not, just so should all pharmacists be equally qualified to properly compound prescriptions, and just so should pharmacy be a proper place and properly equipped for the compounding of prescriptions, and they are not.

While this is deplorable in one way, yet it has its advantages. For this very inequality of fitness and equipment gives an opportunity to the properly equipped pharmacist to bid for the patronage of the physician and the public, in the matter of prescription business.

Assuming then that you are educationally well-equipped, and that your laboratory and prescription-department are provided with all the paraphernalia necessary for the proper and scientific handlings of physicians' prescriptions it becomes your duty to yourself, to your physicians, and to the public to set before the last two, your reasons why they should patronize you in preference to "Tom, Dick and Harry." This can be done in a perfectly legitimate way without sacrificing one iota of your professionalism. Let us take it up *seriatim*:

*Advertising to the Physician.* If your prescription-department is properly equipped and properly kept, invite the physicians of your vicinity to visit it as often as opportunity offers itself. Make it your business to let them see you and your clerks at work. Show them that the drugs and preparations entering into prescription compounds are properly analyzed and carefully standardized. Have a good reference library and put it at the disposal of the prescriber. Perfect your checking system and show your physician how you safeguard his patient's health. Make accuracy, carefulness and cleanliness, your motto and show him that that motto is being lived up to and is not merely for ornamental purposes.

Experiment! Try to improve the appearance and palatability of the pet formula of your physicians and guardedly call their attention to it. Do not attempt to teach them, but submit your improved product for their consideration and approval. Be informed on vehicles and correctives for the drugs most generally used and discuss with your physician orally and by pamphlets the advantages of certain vehicles in the administration of certain drugs.

Take an active interest in your local, state, and national pharmaceutical associations and invite your doctors occasionally to your local meetings. Never, under any consideration, allow a physician to see another's prescription, except by consent of the prescriber; and lastly, rigidly put down counter-prescribing. Briefly stated:—Know your profession and let your physicians know that you know it.

*Advertising to the Public:*—This is even more difficult, at first sight, than advertising to the physician, yet it is comparatively easily accomplished. You may not take the public into your back room, but you can, figuratively speaking, take your back room to the public. Have photographs of your prescription-department reproduced in neat pamphlets telling as much as possible about the arrangement, uses, etc., of the various things appearing in the picture. Show, by photograph, your method of compounding and checking, and describe in detail how it is done. Let the prescription be an advertisement for you from the moment it is brought into your store to the time the medicine reaches the patient's hands, and even beyond that.

If you must follow the trend of modern commercialism in your store, make an exception with your prescription-department. Have the receiving place for incoming prescriptions in a quiet part of the store. The anxious mother holding a prescription, on which, in her opinion, at least, depends the life of the dearly beloved child, is not greatly cheered by the light and airy persiflage floating between Alphonso at the soda-counter and Marie at the candy-stand across the aisle. Let your receiving man be a well-posted man of somewhat mature age. Twenty-one is not very tolerant with sixty-five or over, nor does twenty-one consider that beneath a ragged cloak may be as tender a heart, or even one more tender, than beats beneath the sable coat. A word of sympathy at the proper moment is worth more than all your trading stamps, souvenirs and coupons combined.

Let the receiving man be on the alert to take the prescription as soon as the customer appears with it. Time passes slowly for the bereaved heart and hope begins to be in the ascendancy with the moment the work on the prescription is under way. Let no noisy conversation, or any conversation for that matter, reach the waiting customer from the prescription-department. Suspicion may arise that all of the necessary attention is not centered upon the compounding. As to the medicine itself, too much cannot be said about containers, labels, wrapping, etc. The public can judge the contents only by the package. It has been my experience that people judge, and justly so, that the man who pays attention to the details of the package is not likely to be careless about the contents. In these modern times of machinery above manual labor, one can hardly justify an illegible handwritten label on a bottle, box or jar of medicine. When a type-writing machine is obtainable for as little as ten dollars, why write by hand?

Expensive containers are not essential, neatness and cleanliness and carefulness are far more important. An expensive prescription-bottle "Adorned" with an illegible handwritten label, made still more illegible by smeary blotting and thrown into as many folds as the modern full-dress shirt, by careless pasting is certainly not a thing of joy to behold.

Lastly—do not delay delivery. It is true the medicine may not have to be taken until bedtime, and here it is only 6 p. m., nevertheless, the patient or those caring for him or her are anxiously waiting for it. It is their anchor of hope, why keep them in suspense?

Summarizing: I might say that in advertising a prescription-department, follow the rules of all good advertising. "Have something worth while to talk about and then talk about it in a manner that is worth while."

#### DISCUSSION.

MR. JACKMAN:—"In my opinion the most effectual way is to call upon the physicians and exploit the preparations of your own manufacture. Show them your own preparations of Milk of Magnesia, Elixir of Lactated Pepsin and other preparations in which you take pride. Such detail-work pays better than any other form of advertising."

PROF. RAUBENHEIMER:—"Many methods have been suggested for advertising the prescription-department and much money can be spent foolishly without obtaining results. After all is said, it is the physician who will recommend your pharmacy or not for the preparation of his prescriptions. It is therefore necessary to convince them of the reliability, in fact of the superiority of your prescription-department. Advertise or preach to them your pure drugs and chemicals, your reliable preparations, your facilities and ability for manufacturing, your carefulness, conscientiousness and accuracy in the compounding of prescriptions, with no substitution. Have scrupulous cleanliness not only in your prescription-department but in your entire store. Above all do not advertise your prescription-department as being 'cheap.' Cheapness and good medicine are certainly incompatible. I take especial pride in having the reputation of being 'rather expensive on medicines.'"

MR. SCHULZE:—"I think one should modestly call the attention of the public to this department in your various advertisements. In the sale even of stamps we use an envelope about three inches long and one and three-quarters wide, upon which is printed an advertisement of our prescription-department. These are much appreciated when the stamps are not to be used immediately. We also make window-displays of sick-room requisites among which we intersperse signs calling attention to this particular department."

MR. FERTÉ:—"We advertise mainly to the physicians, sending them circular letters made to appear personal. If this does not appeal to you, write to each of them a personal letter. Your advertising should be high-class, and odd printed matter. Conventional methods do not pay."

PROF. LASCOFF:—"To advertise my prescription-department, I employ the local paper, the church-bulletins, send out circulars and have window-displays, keeping always before the mind of the public that their prescriptions will be accurately dispensed and properly checked."

MR. GRAY:—"Advertise your prescription-department only to physicians. Call their attention to the quality of the drugs you use. Good prescription service is summed up in the following specifications:—A complete outfit of all necessary utensils for dispensing; a system calculated to prevent error; a knowledge of possible deteriorations of stock so as not to dispense any article of lessened or of no value and to be as expeditious as possible consistent with safety, for no one likes to wait long for anything, particularly for medicine."

Question 6: What constitutes good prescription service?

#### WHAT CONSTITUTES GOOD PRESCRIPTION-SERVICE?

FRANKLIN M. APPLE, PHAR. D.

According to the definition, given by Webster, of the word service, it means "the performance of labor for the benefit of another, or at another's command;" also "duty performed in, or appropriate to, any office or charge."

With this definition of the word service accepted as correct, we will proceed to ascertain whom we serve when occupying the position of prescriptionists.

It will be admitted, universally, that we serve our patrons, for whose support we make earnest entreaties, so as to receive as a minimum reward for our services to them, an income sufficient to meet our daily wants.

Prescriptionists also occupy the *role* of servants or assistants to the medical practitioners, who write prescriptions for their patients' welfare; and it must not be overlooked that our services are rendered, automatically, to ourselves and those dependent upon us, in accordance with the character of the labors we perform.

The question is one not only concerning service, or prescription-service, but involves the quality of the service rendered, as note the language of the query: "What constitutes *good* prescription-service?"

To render good prescription-service it has been proven by the experiences of our forefathers, that the qualifications required in the ordinary walks of life to insure success as a result from satisfactory services rendered to society, are not sufficient to qualify one to properly fill the role of prescriptionist.

The education that the average merchant needs, must be re-inforced by education along special lines, coupled with a practical knowledge of the medicinal agents one is expected to handle, acquired by close contact with the same, thereby qualifying one to judge of their purity and quality.

A course of study in a first-class school of pharmacy is an absolutely essential qualification to render good prescription-service in these days of enlightenment and progression, and those days of study must be but the beginning of a life-long term of study and research in order to keep apace with the rapid progress that is being made in medication in various forms; and also to avoid being made the victim of any unscrupulous dealer, who would send out goods of inferior quality, depending upon an ingeniously worded label to release himself from liability of prosecution.

Watch very carefully the labels affixed to goods received, is a wise plan to follow, especially in regard to such goods as are not labeled as U. S. P. or N. F. standard.

The source of supply of one's goods should be most carefully decided upon, in defense of all of the parties one serves, as *quality* should be the most important consideration in assembling one's stock of drugs and all other materials in his establishment.

Having satisfied yourself of the quality of the goods received, it is essential to protect and preserve the same in accordance with the latest knowledge upon the subject, by providing therefor suitable containers and conditions of temperature and moisture that will prevent their deterioration.

One of the most vital factors in rendering good prescription-service to the public and to medical men, is the character of the clerks employed by you.

It is an absolute impossibility for a pharmacist to render a personal service at all times and at all hours to all his patrons, unless he has a very small business and makes a slave of himself, thereby jeopardizing his health and robbing his family and himself of all social life; hence, the human factor must be taken into consideration in the management of our prescription-department and the selection of an assistant is a most important duty to perform.

To have a well-qualified proprietor associate with himself a questionably-qualified clerk is a very unwise act, and I might even say, in some cases, a gross deception, which ultimately will be detected and bring its own reward.

One of the weakest spots in our pharmacy laws is that of the rights that are vested in the semi-prepared clerks, who are granted the privileges of a Q. A., when it is coupled with the broad interpretation of these rights that prevails in some states.

The rights and privileges granted to them in this state is a shame and a disgrace to a professional calling; and you cannot find their counterpart in any other professional walk of life. The rights and privileges they enjoy are the result of bowing down to the demands of commercial considerations at the expense of professional ones.

The candidates examined in this state are now given a more severe test than was the custom some years ago; but a clearer definition of their rights, and greater limitation of the same is essential to an improved prescription-service.

These are the days when the sign "Safety-First" is met with upon all sides, and it is one of the very important reminders that prescriptionists should keep constantly before themselves and their employees, so that when one might relax his vigilance and become somewhat unmindful of his responsibilities, he will have a never failing, untiring sentinel to remind him of his obligations.

The question of safety-first involves every move made in handling the prescription from the time of its receipt until its delivery to the home or the hands of the customer.

Ofttimes the safety-first principle can be attached to the container of the compounded prescription by affixing thereto appropriate labels or stickers; also by using appropriate, distinctive containers.

By the proper use of stickers one can notify the patient what precautions are necessary to properly preserve the medicine, thereby demonstrating one's knowledge of the properties of the same, which leads to a greater degree of confidence in one's ability as a compounder of drugs and prescriptions, with its beneficial results, financially.

In the selection of containers for the results of one's prescription compounding, evidences of care and thought upon this subject can be demonstrated practically, to the decided advantage of his customers. A second-class container for a first-class product is very poor business policy.

The evidences shown in the pharmacist's prescription-department of his knowledge concerning hygiene and bacteriology, will most assuredly leave a lasting impression upon those who have access thereto; and, if one demonstrates, by the location of his prescription-department, that it is an important part of his establishment, greater respect will be shown for it by the public, which includes the medical practitioners.

What may appear to some as a minor, unimportant point, in the conduct of their prescription-departments, is the question of observing the injunctions placed upon the prescription by the creator thereof—the physician.

I have gained and held the support of several medical practitioners, by always placing the copy of the prescription upon the label when so directed. The physicians argued that, if a druggist would leave off of the label the copy, he would

be quite likely to leave out of the prescription an ingredient that he might not have convenient or not in stock.

When serving the medical men as their agents or compounders we must not forget that they are the creators of the prescription, around which they have a perfect right to throw restrictions or safeguards, in their interest, or the interest of their patients. Our commercial interests are the last ones that can receive consideration, and, automatically, oftentimes are best served by respecting fully the instructions appearing upon the prescription.

If the medical adviser wishes to control his patient or observe the results of his prescribing, that is his privilege and, at times, his duty.

Prompt attention should be given to all work and it should not be delayed one minute by anything except by a most urgent call for an emergency necessity of more vital importance than the work in hand. No customer will object to such an act if the proper explanatory remarks are offered if they are needed.

We have now reached the point where, to my mind, the professional phase of prescription-service ends, and where the commercial side of the question presents itself.

The commercial side of this question cannot be divorced from the professional side, except where no charges are made for services and materials and where no expense of delivery are to be taken into consideration; but as we are not engaged in such charity work, from force of necessity we must take into consideration the Biblical statement—"the laborer is worthy of his hire,"—and collect from those whom we serve a recompense for materials supplied and services rendered.

When adjusting the same in an equitable manner the price should consist of the total, resulting from charges for services, plus that for materials supplied. This plan is not followed by some, apparently, judging from a controversy I had recently with a customer, who asserted that she was accustomed to having a prescription, calling for five ingredients, compounded for 50 cents, and one-half of the same for 25 cents. Needless to say, we did not fill one-half the quantity for her at her price, for reasons which we fully explained to her. Such compounders show an absolute lack of ability to intelligently price prescriptions and such action also raises in my mind a question as to the ability of the proprietor to properly compound it.

The delivery of compounded prescriptions by proper help, is of more import than is usually believed by proprietors, and it receives in many cases little thought.

The way to demonstrate claims for first-class goods, a first-class store, and first-class service, is to employ first-class employees from the porter to the prescription clerk, as that these will beget confidence for the unseen services rendered to society.

Where side lines are handled in a drug-store it is policy to have the quality of the same and the services rendered at these departments of such a standard that they will not indirectly injure the reputation of the prescription-department; and it is suicidal to neglect one's prescription work to give attention to side lines.

A library of reference books, volumes of the leading drug journals, which assuredly includes the Journal of the American Pharmaceutical Association, and

an assortment of price lists should be found in every first-class pharmacy—and their pages should show the earmarks of frequent usage.

Needless to say an assortment of proper apparatus should be in stock to carry out the processes that one will be called upon to oversee, for it is surprising how easily some processes can be carried out with the proper apparatus that are difficult to complete without them.

To summarize the whole question I will state that Quality, Safety-First, Equipment and Mentality are the prime essentials in giving good prescription-service.

#### DISCUSSION.

PROF. RAUBENHEIMER:—"Prescriptions should be compounded carefully and conscientiously and its ingredients, as well as the doses, should be properly checked. There is one item which is too frequently sadly neglected, and that is the prompt delivery of medicines. It should be borne in mind that the patient usually waits as long as he possibly can before he consults a physician and that consequently he is in need of the medicine almost immediately. I always insist upon the prompt delivery of all medicines."

MR. SCHULZE:—"I believe good prescription service consists in being properly equipped to fill prescriptions,—first, by having the proper materials, second, by having proper apparatus, third, by having properly-qualified men and fourth by dispensing prescriptions in as neat and attractive a manner as is possible."

MR. FERTÉ:—"Good prescription service consists in dispensing the prescription correctly and knowing your profession sufficiently to know that your work is right. Use the highest class of goods and dispensing conveniences, and have neatness in your work. Lastly use speed in the preparation of medicines required."

PROF. LASCOFF:—"To have good prescription service, the following rules should be observed:—

1. Sanitation. This means absolute cleanliness in all departments of the store
2. Close attention and personal supervision by the proprietor.
3. Buying only drugs and chemicals of the best quality.
4. Courtesy and amiability to all patrons.
5. Avoidance of the 'Just as Good' habit and misrepresentation.
6. The proper standardization of drugs, chemicals and preparations therefrom.
7. Keeping the prescription department entirely separate from the store.
8. Last, and most important—A proper checking system in not alone the prescription, but all departments. In prescription work, a double system of checking is employed. Not only when the ingredients are measured or weighed, but on returning the bottles to the shelves, it is obligatory to check them once more."

Question 7:—What utensils and apparatus do you consider necessary for the prescription-department of the average pharmacy? What further equipment would be desirable?

#### DISCUSSION.

MR. FERTÉ:—"A druggist should have in his prescription-department, a complete assortment of metric and ordinary graduates, (not combinations), mortars of glass, wedgewood and porcelain; a scale sensitive to half a milligramme, one to weigh from one gramme to one hundred grammes; a tablet-machine, a suppository machine, (not one of the cheap cast-iron kind); spatulas of all kinds, steel, rubber and horn; an assortment of sieves, a pill-machine complete and glass slabs for ointments."

MR. SCHULZE:—"The essentials for the prescription-department are,—Three pair of scales for weighing the following maximum quantities, five grains, twenty grains and two ounces. Larger quantities to be weighed on the general dispensing scales. A full set of graduates including those of the metric system; complete sets of apothecaries and metric weights; mortars ranging from two ounces to one gallon in capacity; spatulas ranging from three to six inches and one or two putty knives; a pill-tilt, roller and paddle for rolling pills; an ointment-tilt; a tablet machine; an infusion-mug; a small glass stove or electric infusion-cup; a small microscope; glass stirring-rods, a suppository-mould; casserole or other dish for melting cocoa butter for suppositories, set of small evaporating dishes, small funnels for filtration; blue and red litmus paper and a Florentine flask."

MR. GRAY:—"I consider these things essential in a prescription-department:—One half-dozen mortars, a complete equipment of graduates, from sixty minims to thirty-two fluid ounces, apothecary's measure and from 5 c. c. to one litre in the metric system, an absolutely

dependable prescription scale with weights from one-half grain to two drachms and from five cg. to five grammes; a half-dozen glass funnels, graded sizes; three percolators of varying sizes; two burettes, a half-dozen Florence or Erlenmeyer flasks; a volumetric flask; two evaporating dishes; one casserole; a Bunsen-burner; three glass stirring rods; two beakers; two pipettes, twenty-five and fifty c. c.; a retort-stand; nest of test-tubes; a small file, a pill-tilt, a half-dozen spatulas and a suppository-machine unless the pharmacist makes these by hand."

PROF. LASCOFF:—"As I stated in an address before this section previously, a pharmacist should be in the possession of the following apparatus:—Six mortars and pestles, (porcelain); two glass mortars with pestles, three porcelain evaporating dishes; six spatulas of different sizes, of metal and two horn or bone spatulas; half a dozen glass rods; one infusion-mug; one dozen graduates from one drachm to a quart; one dozen graduates from fifty cm. to one thousand cm.; one accurate base-scale, capable of weighing one grain or less; troy and metric weights from one grain to twelve ounces and from ten milligrams to one thousand grams; two separate poison-closets; two tablet-moulds, triturate and hypodermic; two Florentine flasks, two sieves, one copper water-bath, two percolators, funnels of differing sizes, supports, etc.; a microscope if possible, a sterilizer, a centrifuge if possible; a dozen test-tubes and a burette, and two hydrometers. He should have also a special closet holding the most important U. S. P. reagents, an outfit for urinalysis and the Pharmacopœia, National Formulary and other reference books."

Question 8:—How far may a druggist go in marketing his own preparations, without usurping the rights of physicians or becoming unethical? Would there be any difference, ethically, in marketing preparations made by the druggist or those made by some coöperative organization to which he belongs? Would there be any difference from the same standpoint between preparations of such a coöperative organization and any regular patent-medicine manufacturer?

#### DISCUSSION.

PROF. RAUBENHEIMER:—"I could never understand why objection should be made to a pharmacist manufacturing and marketing his own preparations, especially the simple household remedies. There is a constant demand for these by the American public and the pharmacist who does not cater to that demand loses prestige and revenue. Why should these simple household remedies that are daily called for interfere with the practice of the physician? Of course it is understood that such remedies should be entirely free from habit-forming or narcotic drugs. Above all it is the pharmacist's duty and his birthright to manufacture these medicines himself, and he should boldly state that fact of his making them upon the label. The pharmacist who himself makes these preparations will undoubtedly gain a reputation, not only in his own locality but also farther away from home."

MR. SCHULZE:—"There is no difference in selling preparations, the formula of which is known to the manufacturer only. But there is a difference in marketing the official preparations put up in acceptable packages to meet the demand for household preparations. This is a demand which will continue as long as mankind suffers from coughs, colds, constipation, indigestion, etc., and believe that they are competent to treat themselves. If the pharmacist is wise he will try to induce such people to interview a physician, especially if they return for the preparation of a prescription. It is not always possible to get them to go to a physician, but if it is known that you are giving that advice, physicians will be better satisfied."

MR. GRAY:—"I think a pharmacist may properly recommend his own preparations in all cases where the customer specifies the purpose for which he wants a remedy. As long as he does not diagnose the case he is on the right side. In cases of a specific nature, he should certainly advise the patient to call upon a physician. So far as to marketing coöperative preparations, I would say that, in my opinion, there would be no difference, ethically, in marketing his own preparations or those of a coöperative company provided that one knows the materials of which they are composed."

PROF. LASCOFF:—"It is positively essential for a pharmacist to put up his own preparations, and, in order to be strictly ethical, these should be some of the official preparations, such as Syrup Hypophosphites Co., Beef, Iron and Wine, a good laxative syrup and tablets, cough syrups without opiates, etc., etc. I do not believe that any physician would object to this. One of the great advantages of this practice is that your name is on the preparations and the profit is much greater."

MR. APPLE:—"In the sale of such preparations over the counter it would be inadvisable to use the official titles on the labels, otherwise the people would soon be informed as to their designations and perhaps purchase on their own initiative."

Question 9:—What do you think of tinctures made by diluting fluid extracts?

Should formulas for making tinctures in this way be given on fluid extract bottles?

#### DISCUSSION.

MR. OSSEWARD:—"I think we should be honest and if we use preparations made from fluid extracts we should call them diluted fluid extracts."

DR. SAYRE:—"We find among the samples collected in Kansas, that preparations made from fluid extracts do not attain the standard required."

MR. NITARDY:—"To my mind, tinctures should not be prepared from fluid extracts, but they should be always made according to the U. S. P. or N. F. The last percolate should always be tested for alkaloidal reaction after the proper amount of the menstruum is used."

PROF. LASCOFF:—"I am absolutely opposed to making tinctures by the dilution of fluid extracts. We should follow the official methods in every way. And as that manner of making tinctures is not official, no formulae should be printed on the labels of fluid extracts for the manufacture of tinctures in this way for such a practice tends to lead the profession away from the true standards and methods."

MR. GRAY:—"I think it perfectly proper to make tinctures from fluid extracts or from powdered extracts that are standardized. There is the saving in freight and in containers and it gives the pharmacist a little part in the work when he cannot afford to assay his own tinctures. It is a matter of indifference as to official tinctures whether the formula is printed on the label or not, but it might be well to print such formulas on non-official fluid extracts."

MR. SCHULZE:—"Tinctures made from fluid extracts do not have the appearance of official tinctures and their physiological effect is often different. I think, therefore, that no formulas of such character should be placed on fluid extracts. The practice of making tinctures from concentrates only proceeds from and assist to increase the laziness of pharmacists and their assistants."

MR. FIRTÉ:—"If the tincture and the fluid extract are made with the same menstruum,—ginger for example,—and the fluid extract is not saturated or super-saturated with extractive matter it is proper to use the fluid extract to make a tincture; not otherwise. Couch Grass is another example. Fluid Extract of Couch Grass is simply an infusion preserved, and it is proper to make a diluted infusion from the concentrate. But this is not the case with Digitalis."

PROF. RAUBENHEIMER:—"The practice of printing formulas for making tinctures from fluid extracts should be condemned for the making of such tinctures is bad pharmacy. Fluid extracts are very frequently made by using an entirely different menstruum from that employed in making the tinctures of the same drug."

Question 10:—What are the essential qualities of a good cold cream? Of a good hand lotion? Can you offer a formula embodying these qualities?

#### DISCUSSION.

MR. GRAY:—"The essentials of a formula for cold cream depend upon whether you desire it to be absorbent or non-absorbent. If you desire it to be absorbed you must use a vegetable oil. But if not use mineral oil. In all cases the ingredients must be thoroughly incorporated. I present two formulas which I think will be found to produce superior products."

##### Absorbent Cream.

Oil of peach kernels	8 ounces
White Wax	1 ounce
Spermaceti	1 ounce
Water	2 2/3 ounces
Borax	5 grains
Oil of Rose	25 minims
Oil of Patchouli	1 minim

Mix sec. art.

Dissolve the wax in the oil, use gently heat or preferably a water-bath. When the wax is dissolved, add the water, previously heated, and in which the borax has been dissolved, slowly, constantly stirring with an egg beater. When cold, add the perfume oils.

"Non absorbent, but nicer in appearance, is the product produced by using the following formula."

##### Heavily Cream

White Russian Paraffin Oil	8 ounces
Cerolin and White Wax of each	2 ounces
Water	and one fourth ounces
Borax	5 grains
Oil of Rose	25 minims
Oil of Patchouli	1 minim

Proceed as in the former formula.

Any cheaper odor may be used, such as Almond, Orange Flower or Synthetic Rose.

Hand lotions should have emollient properties, be thick yet easily absorbed or dried on the hands, with a pleasing odor and appearance. Here is a formula which I have found to give great satisfaction:

Powdered Tragacanth .....	1½ ounces
Alcohol .....	16 ounces
Glycerine .....	8 ounces
Benzaldehyde .....	.60 minims
Oil of Lavender flowers .....	.20 minims

Mix thoroughly, and add quickly water enough to make one gallon."

PROF. LASCOFF:—"The essential qualities of a good cold cream are to use pure ingredients, which have a pleasant odor and are bland. The following formula was given to me about fifteen years ago and I have been very successful in its use, receiving quite a demand for the product.

#### Cold Cream.

White Wax .....	12 and a half ounces
Paraffin Oil .....	.48 ounces
Distilled Water .....	.24 ounces
Borax .....	.6 drachms
Oil of Rose .....	q. s.

"For dispensing purposes however the formula of the Pharmacopœia should be used and nothing else. For a good hand-lotion, Glycerine and Rose Water, with Tincture of Benzoin is the best. A good formula was suggested by Dr. Apple, of Philadelphia, printed in the Proceedings of the A. Ph. A."

PROF. RAUBENHEIMER:—"The official formula for Ointment of Rose Water can be modified into a Theatrical Cold Cream by using Paraffin Oil in place of the oil of almonds. The cold cream produced by use of this process has the great advantage of keeping perfectly without change. There is consequently a large demand for such a preparation."

MR. FERTÉ:—"I would ask another question in reply to this query,—Is any Cold Cream particularly good? The one that sells is good. There are so many 'good' formulas available that I think it not necessary to discuss them. 'A good all-around hand and face lotion is thin quince mucilage with a small amount of glycerin, alcohol, benzoin, menthol and some antiseptic and perfume.'"

MR. NITARDY:—"The whole secret of the keeping quality of cold cream is in the proper balance of the ingredients of which it is prepared. A small amount of stearin is of advantage I have found."

MR. OSSEWARD:—"The jars in which the cold cream is placed should be warmed before they are filled, to about the same temperature as the cream, to prevent its contraction from the sides of the receptacle. If this is done this trouble will be avoided."

PROF. RAUBENHEIMER:—"It is also absolutely necessary that the oil and the water should be of like temperature before they are incorporated."

Question 11:—What argument have you in favor of the retail druggist making his own tinctures, syrups, elixirs and other simple pharmaceuticals? Have you any arguments against this practice?

### SHOULD THE RETAIL DRUGGIST MAKE HIS OWN PREPARATIONS?

HOMER C. WASHBURN, PH. C.

To what extent the retail druggist should engage in the manufacture of his own preparations, such as tinctures, syrups, elixirs and other simple pharmaceuticals, is a question that has been much discussed, *pro* and *con*, but which, I believe, is still a live and debatable one.

In considering a subject of this kind, it may be well to note the changes in economic and sociological conditions, which must be held responsible, to a large extent, for much of the business and commercial "status quo" of the present time.

Going back in the history of pharmacy, we find that the druggist, or apothecary, originally made all the preparations and medicines he supplied for the cure or

alleviation of man's ills, and that the drug- and chemical-manufacturing plants, which are such important factors in the world's business of to-day, were not only unknown and un-thought-of, but probably not needed. When we think of all this change that has come within a few generations, and note the concentration of the drug-manufacturing business within a comparatively few commercial centers, we are prone to consider pharmacy as a lost art.

However we view the subject, only a casual observation will convince us that the changed condition is not peculiar to pharmacy, but is just as true in all lines of manufacture and in most of the arts as it is in pharmacy. In short, the change is merely the progress or regress of certain evolutionary conditions that are affecting, alike, nearly all lines of human activity.

Only one-hundred years ago, and in many localities, a great deal less, each family was concerned in the production of nearly all the necessities of life. Not only were the food products grown or gathered by each family for its own needs, but even the wool and the flax that was to constitute its clothing, was raised, spun and weaved, and manufactured into garments by each family for its own use. Not only this, but if a man wanted a wagon or a sled, he made it by the toil of his own hands.

Such illustrations might be enumerated *ad infinitum*, being limited only by the number of articles of family use, but the foregoing will amply illustrate my point. Only I might have added, that most of the herbs used in the household remedies, which were so popular in those days, were also collected by the family for its own use.

But times have changed, and whether we view this kaleidoscopic, evolutionary change as of benefit or of harm, we must bow, to a certain extent, to the tendencies of the times.

To-day it is not uncommon to find our young people, and especially those among the city bred, who, while wearing the finest of raiment and traveling in conveyances that are the best product of the skilled mechanic's art, find their most serious employment in idleness and in attending places of amusement, little knowing, and caring less, where the clothes came from that they wear, or by whose toil they are permitted to enjoy the ever-changing variety of modern society.

The sociologist and the psychologist have very concrete notions as to the effects of such idleness, upon the moral and spiritual tendencies of our time, and I quite agree with them, but I fully believe that it is only one phase of modern, industrial tendencies and that we should do whatever is possible to correct the evils of this tendency. However, we will be able to accomplish more real and lasting good by methods that are evolutionary and not revolutionary—by working among our own people in our own chosen profession and doing whatever we can in a quiet, but no less positive way, to encourage habits of industry and usefulness among those, who being our apprentices to-day, will be our successors to-morrow.

Personally, I do not believe that many of our modern, economic and sociologic tendencies make for the betterment of the race. Centralization of production, along each of the various lines of business, undoubtedly results in the production of articles at a lower cost, but it also results in the enforced idleness of others,

and to my mind, idleness is the most dangerous tendency of our time. I believe that this talk about the concentration and minimization of labor, in order to allow more time for intellectual and spiritual development is nonsensical. On the other hand, I do believe that hard work and even hardships, such as our forefathers had to endure, made for better intellectual and spiritual growth than the present-day, easy mode of life. In support of this contention, I would merely point to the names of Jefferson, Webster and Clay, or to Whittier, Emerson and Lowell—products all of the days when hard work and a struggle for existence was the rule. According to President Eliot's definition of education, Abraham Lincoln was the best educated man of his time, and the story of the struggles and hardships of his life are well known to all.

So, coming specifically to the point under consideration, I believe that the more a druggist plies the fundamental warp and woof of his profession, the more nearly will he deserve being called a professional man. The idea that has gained ground in later years, that the druggist is merely a store-keeper or business man is only the logical and inevitable outcome of his tendency to handle the products of other's labor, allowing the skill and the science of his predecessors to gradually slip away.

I am not advocating that the retail druggist should attempt to prepare all his preparations. Many of them would involve too large an outlay of apparatus for the amounts he would use; others that require standardization, and especially those that can only be standardized physiologically, require a degree of expert knowledge and *technique* that we can not logically expect the retail druggist to acquire, but in the average run of preparations, such as most of the tinctures, syrups, elixirs, etc., for which only a reasonable amount of expert knowledge is required, I believe that the benefit derived would justify the effort involved. And, in this connection, let me say, that the benefits gained can not all be reckoned in dollars or cents. There should be some pecuniary saving, to be sure, in such articles as are used in fairly large amounts, because the same shelf-bottle or container will serve its purpose indefinitely, while with every purchase of such article, from the manufacturer or jobber, a different bottle, label and stopper are used. Also the average retail druggist, or his clerks, could find time to make many of these preparations during moments that are not otherwise employed, and no one will contend that, in buying these preparations ready-made, we are not paying for the time, labor and expert knowledge of the individual who does manufacture them. Add to this the freight and cartage. These savings are mere trifles to be sure, but the drug business is made up of trifles, and in the aggregate they amount to considerable.

Even though the expense involved were as much as the article would cost, there are still, at least, two things to be considered—the psychological effect upon the druggist himself, and that upon the customer. The druggist who clings to at least a portion of the professional and technical phases of his calling, is benefited psychologically, at least. He takes more pride in his work, feels a greater confidence in himself and develops a higher sense of responsibility, all of which undoubtedly increase his usefulness to the community. These make him indeed a better man and a better druggist.

From the view-point of the customer, it is scarcely necessary to say that the

druggist who is known to manufacture a part of the preparations he handles, inspires confidence. The layman is usually a practical sort of an individual, and generally views the druggist as a professional, or just a plain business man, in about the ratio he deserves.

Just what preparations should be made by the retail druggist, is largely a matter of local conditions, and each individual is best qualified to answer the question for himself. But he can only do so, with any degree of intelligence, after a careful study of the matter. I would not advise any druggist who has not been in the habit of making his preparations, or one who is just starting in, to plunge into the matter blindly and attempt to make any considerable number at the start, but rather to begin gradually, increasing the number from time to time as seems best. Under such a plan, I believe an active interest will soon develop in any man deserving of the name of druggist, and that with an average degree of business acumen, it can soon be determined what preparations can be made to the best advantage.

To the list of official pharmaceuticals, I would strongly urge the manufacture of such preparations as cold creams, toilet lotions, etc. Formulæ, from which preparations of this type may be made, are easily accessible, and the confidence-inspiring influence their use gives the customer, is certainly worth while.

In the foregoing arguments, I have purposely endeavored to treat the subject academically, laying special stress on the sociological and psychological phases. Indeed, I believe that any business with the psychology of that business left out, is comparable to a boat simply drifting with the current and without the directing influence of a guiding helm.

#### DISCUSSION.

PROF. LASCOTT:—"If a man desires to call himself a pharmacist, he must, of necessity and desire, make all of the preparations named, to be at all worthy of that name. Not only that, but it is cheaper and his preparations are better and fresher."

MR. GRAY:—"In my opinion a druggist should make all of his elixirs, syrups, emulsions and in fact everything he uses in the way of preparations, excepting fluid extracts, tinctures, pills and tablets. With these exceptions it pays to do so."

MR. SHULZE:—"The arguments are all in favor of the druggist manufacturing his preparations. There is not one good argument against this practice. First and foremost, he knows just what they contain. Second, they are properly made and third, he can save from twenty to forty per cent. Some may consider the last item of the first importance."

MR. FERTÉ:—"It does not pay to make tinctures, because of the loss of the alcohol remaining in the marc. The same is true of fluid extracts. But it does pay to make elixirs, syrups, ointments and many other preparations. There is no argument against this practice."

PROF. RACHENHEIMER:—"The retail druggist who aspires to the name of pharmacist, should most certainly make his pharmaceuticals. This practice should not be restricted to simple preparations, such as mentioned in the query, but he should also make the more complex preparations, those which require pharmaceutical skill, which every pharmacist should have acquired in his college course and also in his daily practice, if he has made use of the opportunities presented to him."

Question 12: How much of the trouble encountered by pharmacists in making the official preparations is due to the use of crude materials of improper quality, and the subsequent improper keeping of the finished product?

#### DISCUSSION.

MR. NITARDY:—"In my opinion most of the trouble is caused by the use of improper crude materials rather than to improper keeping of the finished product."

PROF. RACHENHEIMER:—"I think that the much talked-of poor quality of crude materials, of our drugs and chemicals is entirely unwarranted. The pharmacist who is willing to pay

the price for them can always obtain drugs which are of U. S. P. quality. Another important factor in the situation is that the average pharmacist seldom examines or tests the drugs he buys. As soon as he commences to do so and the wholesale druggist becomes acquainted with the fact, then the pharmacist, upon the payment of a fair price will be supplied with drugs and chemicals of U. S. P. quality."

MR. FERTÉ:—"Not much of the trouble is due to drugs of poor quality. It is caused in the majority of cases by ignorance of the *modus operandi*, I believe."

PROF. LASCOFF:—"In the manufacture of official preparations it must be understood that the materials must be of A-1 quality, and if the preparation is not a stable one, it should not be made in large quantities, and should be preserved in well-corked amber bottles and at a medium temperature. If care is not taken in the preservation of such preparations, there is always trouble."

Question 13:—Did you find it necessary to have your Pharmacopœia re-bound before it was subjected to much wear? Is the binding as substantial as it should be or does it compare favorably with the bindings of other books intended for constant use?

#### DISCUSSION.

PROF. LASCOFF:—"This question was brought up at a meeting recently held in the New York College of Pharmacy and Professor Reinington stated that the binding of the U. S. P. (IX) would be far superior to any other binding of the previous volumes. My personal experience is that I have had mine re-bound twice, and then had to buy a new book with a flexible cover."

MR. SCHULZE:—"I think the binding of the Pharmacopœia compared favorably with that of other books, although we used it a great deal more."

MR. FERTÉ:—"We have not been obliged to have our Pharmacopœia re-bound, probably because I covered it with heavy wrapping-paper as soon as I received it. At practically no cost this covering will last two or three years and then can be renewed."

PROF. RAUBENHEIMER:—"Unlucky '13 and unlucky binding of the Pharmacopœia were united. After the short use of one year, the poor binding of our good Pharmacopœia gave way and its leaves were scattered in the many corners of my store. An interleaved and leather-bound copy was then procured at the advanced price, but its fate was the same. Of course, I admit that I make frequent daily use of the volume and could hardly expect that one copy should last ten years. But its binding can be, and undoubtedly will be, greatly improved upon. By the way, the United State Pharmacopœia is not the only one which has a poor binding. The French Codex is bound equally bad if not worse."

DR. WILBERT:—"I am informed that the Board of Trustees has made proper arrangements for a most substantial binding for the new Pharmacopœia."

MR. WHITE:—"The practice of making notes in the Pharmacopœia is not a good one. It increases the use of the volume and therefore tends to its deterioration. I use a card-index for such purposes. These cards can be renewed at any time at but very little expense, and their use saves the use of the Pharmacopœia."

Question 14:—Has the average pharmacist such reference books as he should have? Would \$50.00 or \$100.00, expended on books of value to pharmacists be a paying investment from a commercial stand-point? What books would you include in a five-foot shelf of reference books for the country pharmacist; for the city pharmacist?

#### DISCUSSION.

MR. SCHULZE:—"Every pharmacist should possess a Pharmacopœia and a National Formulary. In addition to these, he should have at hand a first-class treatise on pharmacy, and also one on chemistry. He should subscribe to at least one good drug-journal. All of these will not cost \$50.00 and they will answer all practical purposes. These books, with the publications which the membership in the A. Ph. A. will bring him to keep in touch with the advance of pharmacy, are sufficient for the ordinary pharmacist."

MR. FERTÉ:—"The average pharmacist is not equipped with books as he should be. There is no need of expending more than fifty dollars for a working-library. That much, however, I consider a good investment for him."

MR. GRAY:—"I do not think the average pharmacist has as many reference books as he should have; and believe that fifty dollars for books is a good paying investment. I would recommend the following books for a five-foot library shelf: U. S. Pharmacopœia, U. S.

Dispensatory, *Materia Medica* and Pharmacology (Culbreth), National Formulary, Manual in Chemistry (Luff and Candy), Squire's Companion to the British Pharmacopœia, Latin Dictionary, Chemical Dictionary, Merck's Index.

PROF. RAUBENHEIMER:—"I have thoroughly investigated this question, being somewhat of a 'book-worm' myself. The conclusion I have reached is that the average library of the average pharmacist of the United States is a disgrace to the profession. Is it not sad that, even in the Empire State of New York, which pretends to be a leader in things pharmaceutical, a provision had to be made in the Pharmacy Law requiring every pharmacist to have in his pharmacy copies of the Pharmacopœia and the National Formulary? The pharmacist who invests fifty or one hundred dollars in books pertaining to pharmacy, chemistry, botany, pharmacognosy and toxicology will receive an abundant return within a very short time. I have had in mind the preparation of a list of books which should be possessed by every pharmacist, both in city and in country and hope soon to furnish such a list as is called for by the query."

PROF. LASCOFF:—"Very few pharmacists have a complete library, or even the most necessary books of reference. In my opinion, fifty dollars to one hundred dollars expended on books of value to pharmacists would be a paying investment from a commercial standpoint, as without books of reference I do not think any reputable pharmacist could get along. I would suggest the following list of books as desirable for a library. For city pharmacist: U. S. Pharmacopœia; National Formulary; U. S. Dispensatory; Hager (3 volumes); Squire's Companion to British Pharmacopœia; Text Books, (Arny's, Remington's, Caspari's); Volumetric Analysis (Coblentz & Vorisek or Schimpf); Latin Grammar; Incompatibilities in Prescriptions (Ruddiman); Weights and Measures; Outlines of Physiology; Botany and Pharmacognosy (Kraemer); Polyglotta (Rosseau); Proceedings of A. Ph. A.; Manuals of Toxicology and Microscopy; Journal American Chemical Society; Purdy's Practical Urinalysis; Journal Am. Ass. Advancement of Science; Five Pharmaceutical Journals (to be bound); Pharmacology and Therapeutics (Cushny); *Materia Medica* (Rusby). For country pharmacists: U. S. Pharmacopœia; National Formulary; U. S. Dispensatory; Hager (3 volumes); Incompatibilities in Prescriptions (Ruddiman); Proceedings of A. Ph. A.; Two Pharmaceutical Journals (to be bound.)"

DR. WILBERT:—"The Pharmacopœia was not much in evidence in New York State before its possession was made compulsory. Some two years ago I took it upon myself to make an investigation into this matter. I found some pharmacopœias, but they were not like those of which Mr. Jones and Prof. Raubenhimer have spoken. Those I found were in a most excellent state of preservation and they had a thick layer of dust on top of them."

MR. OSSEWARD:—"It seems strange to me that any pharmacist can get along without a pharmacopœia. We have constant use not only for the pharmacopœia of this country but also for those of Britain, France, Germany, Holland and Scandinavia." In addition to the books mentioned I would suggest one entitled "*Modern Materia Medica*."

MR. NITARDY:—"I have found a book entitled '*Elementary Chemistry*,' by Dr. Gordeen, a very good book for a retail pharmacist to have."

PROF. RAUBENHEIMER:—"The most thorough book of which I have knowledge is Von Schmidt's *Pharmaceutical Chemistry*. It is printed in German and, so far as I know it has not been translated. The author of the book is an honorary member of our association."

Mr. Richardson read the following paper in reply to this query:—

## DRUG-STORE LIBRARIES.

FRANK RICHARDSON, PH. G.

The average pharmacist has not the reference-books that he should have. The average drug store library in this section is composed of the books required by the law, viz.: The United States Pharmacopœia, The National Formulary, and one of the Dispensatories, and the pharmacist without a good working-library, is like a mechanic trying to work without suitable tools.

The pharmacist in most rural communities, is looked upon as a man able to answer all sorts of questions and nothing he can do will add more to his prestige than his willingness and ability to answer satisfactorily the many questions asked by his customers, and to do this he must have the tools to work with.

In my own store I have several times the five feet mentioned in the question submitted.

I would recommend for the country pharmacist the following:—

The United States Pharmacopœia, The United States Dispensatory, Remington's Practice of Pharmacy, The Scientific American Cyclopedia of Formulas, Simon's Manual of Chemistry, Diseases of Cattle, (Department Agriculture), Scoville's Art of Compounding, Homeopathic Pharmacopœia, Gould's Medical Dictionary, The National Formulary, The National Dispensatory, The Era Formulary, Manual of Toxicology, (Brundage), Culbreth's Materia Medica, Diseases of Horses, (Department of Agriculture), Ruddiman's Incompatibles, Schimpf's Volumetric Analysis, The Modern Materia Medica.

Add to these the Legislative Manual published by the State, for reference in regard to political questions that are often referred to the pharmacist, and the World Almanac in answering general questions.

In addition to the above books every pharmacist should take an active interest in and be affiliated with his State Association, and lend his support to their efforts for the betterment of pharmacy and also the American Pharmaceutical Association and have its valuable Year Book at hand for ready reference. Last, but not least, every pharmacist who desires to keep abreast of the times, should be a subscriber and careful reader of one or more of the splendid journals devoted to pharmacy.

This list, of course, could be largely extended, but I believe that with such a library, the pharmacist would be well equipped to meet any emergency and would find the money expended in procuring it well invested.

For the city store much the same list would apply, with the exception of the books on Diseases of Horses and Cattle.

Question 15:—Do pharmacists as a rule select the right kind of boys for apprentices, considering that they are the timber from which the pharmacy of to-morrow will be built?

## PHARMACISTS AND THE RIGHT KIND OF APPRENTICES.

---

ROBERT P. FISCHIELIS, B. S., PHAR. D.

---

The query, "Do pharmacists as a rule select the right kind of boys for apprentices, considering that they are the timber from which pharmacy of to-morrow will be built?" requires the consideration of several existing conditions before it can be answered intelligently.

First of all, what is the modern conception of the word "apprentice," as applied to pharmacy? Is an apprentice a boy whose environment necessitates the earning of money outside of school hours, in order that he may obtain a common grammar-school education, and who finds that the corner drug-store can use him during the hours he does not spend at school, both day and night? Is an apprentice a high-school student who earns his "pin" money, or more, by afternoon or evening work in a drug-store? Or, is an apprentice a high-school graduate who selects pharmacy as his life work as other high-school graduates select medicine, law, architecture, or finance?

The grammar-school boy, first mentioned, as a rule does not get very far along in the practice of pharmacy. He is selected, not to be taught the profession, but because his labor is cheap and he is able to run errands, clean up, and relieve the proprietor and other help, of various unpleasant but necessary duties. Unless this boy is very energetic and becomes very much interested in pharmacy as a life work, because of an inherent liking of the profession as he sees it practiced, he only continues the work as long as it is a means to his particular end, earning money. Perhaps this boy may be fortunate enough to be in the employ of a druggist who realizes that it is his duty to sacrifice a small part of his time for the purpose of awakening an interest for pharmacy in this prospective, by showing and explaining to him that there is more to our profession than the mere selling of wares over the counter. But the chances of affiliation with such a "preceptor" are becoming rarer every day.

The non-graduate high-school student before mentioned, is more apt to become a druggist than either of the other two. Pharmacy usually appeals to him as a commercial proposition. He knows that it will be necessary to do some studying or perhaps take a college course before he can qualify for the work, but considers the time thus spent, a good investment. He has had one or more years of high-schooling and that will admit him to most colleges of pharmacy. The standing which a pharmacist enjoys in most communities, and the commercial prospects are the things that appeal to him and even though his natural inclinations may be toward another line of work, the higher requirements and the longer "apprenticeship" place it beyond his reach and pharmacy becomes his choice.

To be sure, many of this class, as well as of the other class named, really develop a liking for the profession of pharmacy and practice the profession for its own sake as well as for the living it earns them. But there is a difference between inherent love and acquired affection.

We come now to the high school graduate, who through some one of several influences has acquired so great a liking for pharmacy, that he decides to make it his life work. Such young men are very desirable apprentices, but in comparison with other fields of endeavor, what prospects does pharmacy hold out to them?

The president of a state pharmaceutical association said in his address at the 1914 convention of that association, "we have become commercialized to a certain extent, and the majority of us do not have any prescription business worthy of mention."

The author of a book on commercial pharmacy makes these statements:

"For permanent success in present-day pharmacy, you should be a good business man rather than a good prescription man.

"The biggest successes in pharmacy are the big stores in the large cities and their success is due to their knowledge and practice of business methods. They have set aside their professional scruples, and have added side line after side line, until their stores look more like department stores than pharmacies.

These statements voice the trend of pharmacy unmistakably and leave with us a fair idea of the future.

Experience is proving that few of the men who choose pharmacy because they like it, stick to the practice in retail drug-stores. The majority, finding that they

are unable to use their knowledge of the subject in the retail drug business, without at the same time doing the non-pharmaceutical work required in a modern drug-store, turn to manufacturing chemical or pharmaceutical houses, or take further courses in chemistry, bacteriology, materia medica and like subjects and thus qualify for good positions as analysts, teachers or laboratory workers.

It is my belief that there are just as many young men to-day who seek to become "professional pharmacists," as there ever were, but the commercial trend of retail pharmacy has made that business undesirable for them and they are turning in large numbers to positions with manufacturing houses, who are gradually picking up the professional side of our calling which the retailer is casting aside.

The author, whom I have already quoted, says that it pays a progressive druggist to hire a clerk at about \$20 per week to take care of his prescription department, while he himself makes the side lines "go." How much time is such a man going to take to help educate apprentices and make pharmacy the profession, a worth-while calling for young men?

But perhaps the solution of the problem is nearer a consummation than appearances indicate. If those proprietors who are commercially inclined employ helpers who incline toward professionalism, and those who are professionally inclined, on the other hand, employ commercially-trained help, both ends of the business should be well taken care of and the apprentice, seeing both ends of the work of a drug-store properly taken care of is at liberty to choose between the two, when the time comes for him to assert himself. However, personal attention is necessary in either case to make the apprentice at all valuable.

That a division of drug-stores into pharmacies and shops is being given some serious consideration, is evidenced by the fact that a state pharmaceutical association at its last meeting, appointed a committee of eleven men to consider the subject and report at the next meeting. Such a condition would naturally solve the apprentice problem.

To my mind the apprentices in pharmacy to-day are not getting a fair deal from the majority of employers. Some consideration should be taken of a man's inherent abilities and preceptors should be frank in telling a boy whether or not he is fitted for the work. A frank statement of the opportunities in present-day pharmacy should also be given to the apprentice before he has gone too far into the work to be able to turn to something else more suitable for him. I would say that pharmacists as a rule do not give enough time and thought to the selection of apprentices and forget that an apprentice is an investment and that this investment, more so than any other in the store, will bring a high or low rate of interest, depending upon the amount of time the employer is willing to devote to its development.

#### DISCUSSION.

PROF. LASCOFF:—"Pharmacists as a rule do not select the right kind of boys for apprentices, they choose them with regard to salary and do not take into consideration their general education and other things so essential to the development of a pharmacist. In my opinion a pharmacist should be a high-school graduate before he studies Pharmacy. That is the case in European countries."

PROF. RAUBENHEIMER:—"To my great regret I am compelled to answer this query in the negative. It seems as if the apprenticeship which was so greatly valued by our fathers in Pharmacy is neglected, sadly neglected. It should be remembered above all, that besides the

necessary preliminary education, the apprentice must possess something which is still more important and that is a love for professional pharmacy. In order to create and foster such love I have found that the study of the History of Pharmacy supplies this want and have instituted such a course in the College of Pharmacy at Jersey City."

MR. FERTÉ:—"As a rule pharmacists make no selection whatever. They hire the boy whom they can drive the hardest for the least pay. No attention is paid to 'timber.'"

MR. SCHULZE:—"No deliberate selection is usually made. A boy of the lawful age is taken into the store and allowed to make his way to the sale of soda, cigars. He then gradually adds to these the sale of scidlitz powders, patent medicines and package goods. In a few years this boy with an immature mind is encouraged to take the examination for the Assistant's certificate. After a few years he takes the examination for a Pharmacist. Passing this, he with his incomplete education becomes a full-fledged pharmacist. No boy from the fifth and sixth grade or even from the seventh grade of our public schools can properly comprehend the mysteries of pharmacy and chemistry and the sooner we insist that our apprentices shall be high-school graduates the better standing will pharmacy attain in the eyes of the public."

MR. JONES:—"My experience is that a person should be careful in their selection of an apprentice if they expect to get service which is valuable. But the more enterprising and energetic young man you get, the quicker he leaves you for some larger field."

MR. NITARDY:—"If we will select an apprentice when we really want an apprentice, and hire an errand-boy when we want one, we may be able to help this problem a little. There is no use in hiring an apprentice when you merely want a bottle-washer or a window-cleaner."

MR. JONES:—"I claim that a man will not make a good proprietor unless he learns the business from the ground up."

MR. NITARDY:—"I mean that we should not hire an apprentice unless we intend to move them up. If there is no such intention we should simply hire an errand-boy or porter."

Question 16:—What plan would you suggest to make our profession more attractive to the better class of young men?

PROF. LASCOFF:—"To make our profession more attractive to the better class of young men, I would suggest that we conduct our pharmacies upon a professional basis. The pharmacists should do away with side-lines which do not belong to the profession, and if you do keep side-lines, keep your prescription-department distinct and separate from your store. Do not devote all the space in the front to side-lines, but give room for a display of crude drugs, etc. This will attract the young men more than a display of shoe-laces or parasols, which articles displayed in your store would certainly not attract any one to its study."

DR. WILBERT:—"We could probably make the business more attractive by doing a strictly professional business, a pharmacy business, and by making others do the same business. Then those who do not belong in the business will get out and leave it much to its good. If this could be accomplished the business of Pharmacy would be much more attractive to the better class of men."

MR. OSSEWARD:—"I heartily agree with Dr. Wilbert. If the pharmacists would do their duty and see also that others did theirs, the trade would benefit. When I was on a State Board we received a great many complaints from men about the way their brother pharmacists conducted their businesses, but if we asked the complainants to testify to the truth of their statements the answer would be, 'O, please don't use my name in it.' Now, the druggists should take their part of the responsibility."

MR. JONES:—"I do not agree with Dr. Lascoff in making the business more professional or in separating the pharmacy from the side-lines. Combining these more closely is to my mind the better way."

PROF. RAUBENHEIMER:—"Besides the shorter hours and more pay which are proposed I would point out the position the druggist occupies in the community as a reason to attract young men to the profession. As a profession Pharmacy is certainly the equal of Medicine as a guardian of the health and the welfare of the people. Pharmacists may well become physiological chemists and thereby rise to high positions everywhere. In considering the question of a choice of a profession with my son I had no difficulty in convincing him that Pharmacy was the most desirable profession for him to adopt for his life work."

MR. SCHULZE:—"I think we should insist on having it understood that Pharmacy is of dual nature, that is, professional and commercial, and that there is nothing degrading in commerce, unless a man himself degrades it by dealing in immoral or illegal goods. Then we should lessen the hours of confinement, by opening our stores a little later and closing them a little earlier at night, giving more time to clerks, at least two evenings a week, with a part of each Sunday. Have then, rather than Pharmacy, after all, requires no more from its followers than other professions, and not as those applications as Medicine, nor is it as unpleasant in many ways."

Mr. Osseward read Dr. Groat's paper on "The Chemistry of Cold Creams."

## THE CHEMISTRY OF COLD CREAMS.

H. S. GROAT.

There has always been a noticeable difference between cold creams made with, and those made without, borax. Those made with borax are always whiter and fluffier, and seemingly not as greasy as the others, due to the uniting of the borax chemically with the palmate, stearate, or fatty alcohol of the hard and soft bases. This reaction only takes place when the oil solutions and the aqueous solution of borax are both heated to above 120 degrees F., as the esters or organic borates are not formed below that temperature.

When spermaceti is used as the base in the manufacture of the cold cream, borax unites chemically with cetin its chief constituent in a reaction similar to the reaction of borax and glycerin in the manufacture of boroglycerin. In a similar manner borax reacts with myricyl palmate and ricinolein, the chief constituents of white wax and castor oil respectively, when either white wax or castor oil is used as the principal base. With almond oil as a base borax acts likewise with the three main constituents of almond oil, palmitin-myricyl palmitate, olein-glyceride of oleic acid, and stearin-glyceride of stearic acid.

When glycerine and borax are heated together, the chemical result is boroglycerin, sodium meta borate and boric acid, or meta boric acid and water.

Take the following common formula for cold cream:

Petrolatum Liquidum.....	120
Cera Alba.....	40
Aqua .....	40
Sod. Bibor.....	1.4

Here we have white wax as the hard base, its chief constituent myricyl palmate, being attacked by the borax forming palmitic borate.

Another common formula is:—

Oleum Ricini.....	180
Cetaceum .....	60
Cera Alba.....	15
Sodium Biborate.....	1.5
Oleum Rosæ.	
Oleum Amygdalæ Amaræ aa q. s.	

In this case the borax enters into three separate chemical reactions with the white wax, spermaceti, and castor oil respectively. We have given above the

reaction of borax with white wax, we shall now take up the reaction of borax with spermaceti. The chief constituent of spermaceti is cetin-cetyl palmitate— $3C_{16}H_{33}O.O C_{16}H_{31}$ —which is attacked by the borax forming palmitic borate, as in the case of white wax and cetylic acid as a by-product instead of the myricylic acid, which is the by-product when white wax is used.

With the castor oil, borax combines with its chief constituent ricinolin-glycerine of ricinoleic acid, and forms glyceryl borate or boroglycerin, ricinoleic acid, sodium metaborate, and boric acid or water and metaboric acid.

There is another and more popular class of cold creams, of which almond oil is the base. The extreme popularity of these creams is due to the fact that the use of almond oil as the base is a decided advantage, as it is of a purely endermatic nature, that characteristic so greatly desired in this class of toilet preparations. Of the many formulæ of this class tried out the following gives the most universal satisfaction:—

Oleum Amygdake Dulcis.....	77
Lanum .....	15
Paraffinum .....	18
Cera Alba.....	18
Sod. Bibor.....	1.5
Liq. Hydrog. Diox.....	1.5
Oleum Rosæ Geranium.....	.2
Aqua Dist.....	27
Oleum Rosæ.....	.4

With the almond oil the borax enters into a triple chemical reaction with its chief constituents, the glycerides olein, palmitin, and stearin. Glyceryl borate or boroglycerin is the resulting chemical compound formed in each case. With olein, which is a glyceride of oleic acid, the reaction is

With palmitin the reaction is

With stearin the reaction is

Mr. Ford read the following paper:—

### RANDOM NOTES.

THOMAS D. MCELHENIE, PH. G.

*Aqua Anethi*.—Wishing to replenish a supply of Aqua Anethi I could find no formula except the British on Page 174, U. S. Disp., 19th Ed.—directing distillation. Not having the necessary apparatus or time, I adapted to the case the official process for most of the aromatic waters, as follows:—

R	Ol. Carui.....	2 cc.
	Ol. Anethi Sem.....	2 cc.
	Talcum.....	30 gm.
	Water ad.....	2000 cc.

Triturate and filter as usual.

The product is entirely satisfactory.

*Blue Pills*.—For several years my habit has been to dispense for Blue Pills over the counter five-grain Capsules of Powdered Blue Mass, and the patient gets a better thing than ready-made pills whether made by myself or a factory.

(*Capsule Blandii C. Arsenici et Strychnia*).—The official process for the Pill of Ferrous Carbonate and the processes of the various makers who furnish the pills ready-made, do not and cannot produce a pill of *ferrous* carbonate. By the time the work is done the moisture present has changed nearly or quite all of the salt to the *ferric* salt. Pondering these things, I hit on the plan of using the essential ingredients dried, and packing speedily into capsules.

Starting with a warm mortar of good size, drop in the necessary dispensary tablets, for one grain each Arsenious Acid and Strychnia Sulphate and follow with Potass. Carb. Purif. Recentis 250 grains. Rub to fine powder and add Ferri Sulph. Exsicc. 250 grains in fine powder. Rub lightly enough to mix well and pack into No. 4 Capsules, which will hold five grains. Keep in corked bottles. These will produce *Nascent ferrous Carbonate* in the stomach at the time of disintegration. I have some of the capsules several months old unchanged.

*Preparation of Herbs, etc.*.—To prepare leaves or herbs for maceration or percolation moisten the material with water in a suitable basin and cover, allowing to stand over night so that the leaf is in about the natural fresh condition. Then when the worshipful mistress of Domestic Lodge No. 1 is not looking, borrow her meat chopper, sneak back to the store and in a little while you have your leaves coarsely cut. Allow them to dry and proceed with the operation.

I have prepared Jaborandi and Henna in this way and for many others it would work equally well. Our distinguished member, Mr. Ebert, years ago proposed the same little tool for granulating Opium.

*Elix. Aromaticum*.—Four years of continuous use of the formula of Mr. R. R.

Johnston of Bucyrus, Ohio, for this elixir only confirms my good opinion. It contains 6 $\frac{1}{4}$ % Alcohol, and that is enough for any use I can think of. The formula was published in the Pharm. Era, May 20, 1909, P. 469. As it was not mentioned in the Report on Progress of Pharmacy for 1909 or 1910. I conclude some members may have missed it, and therefore will transcribe it here.

R	Sp. Aurantii Co.....	12.	cc.
	Talcum Purif.....	30.	gm.
Triturate thoroughly and add in portions			
	Syrup .....	363	cc.
Add gradually in same manner			
	Glycerine .....	93.7	cc.
	Alcohol .....	62.5	"
	Water .....	468.7	"
Filter through wetted filter and follow with mixture of			
	Alcohol .....	10%	} by vol.
	Glycerine .....	15%	
	Water .....	75%	
	to make 1000 cc.		

After two or three trials I have found it to be improved by using about 20% of Concent. Syr. Orange in place of so much Simple Syrup.

Worked out for five gallons it runs as follows:—

Sp. Aurantii Co.....	240 cc.	240 cc.
Talcum .....	600 gm.	600 grams
Syr. Orange Conc.....	51 fl. oz.	1452 cc.
Syrup .....	195 " "	5808 cc.
Glycerine .....	64 " "	1875 cc.
Alcohol .....	42 " "	1250 cc.
Water.....ad. Cong. V		qs. ad. 20,000 cc.

*Lin. Camphora Benzoeata*:—To an educated nose a sniff at the mouth of a bottle of a perfectly normal academic and official liniment of Camphor brings to one's mind just a trace of an odor which resembles the first cousin of rancidity. I have had in mind for a long time to try benzoin for that and having occasion recently to make up 2000 cc., I added 2% of Siam Benzoin.

Following the suggestion made by Mr. Raubenheimer a few years ago I used Oleum Sesami weighing 1600 grams into a tared bottle, and dropping in 400 grams of coarsely powdered Camphor and indicating by a strip label the measure of 2000 grams, then adding 40 grams coarsely powdered Siam Benzoin and allowing to stand until wanted, when it was filtered, and furnished a fine product. Camphor dissolving more rapidly than in Ol. Gossypii.

Mr. Nitardy moved that the papers presented by authors not present be declared as read and referred for publication. Motion carried.

Mr. Osseward was then installed as Chairman of the Section and made the following address:—

"I will say to you gentlemen that I deem it an honor to be selected as Chairman, as I told one of the gentlemen who asked me about this nomination, that I had my mind made up

when I came to Detroit that I would not accept an office of any kind. He wanted to know why, and I said because I have so much business in my own State that I do not see how I can do justice to the work. I think the members of the Association should be a little more lenient with the Chairman, as it is hard work to get papers as it means a lot of worry, and if the worry was taken away it would be a pleasure. I am going to try to see if I cannot get a little assistance from the start so that a little worry can be taken off my mind, and if that can be done I think the work will be pleasure instead of a pressure, because the Chairman has to work very hard. I put out 200 invitations for papers and received three replies. I trust that some of the members will make promise of a paper. I will do everything I can to make this Section a success next year.

Mr. Osseward then introduced Mr. Becker as Secretary.

Mr. Becker spoke as follows:

I feel that a few words in defense of my position is necessary. I came here also with the intention of not taking an official connection with any of the Section. The principal reason for my not wanting to serve, was because I feel that my services are very inadequate because of the very poor results obtained from my efforts. I do not conduct successfully the section of work assigned to me. In regard to papers, I think that one plea is sufficient for a gentleman. I will try to do the best I can as Secretary.

Mr. Osseward then introduced Mr. Jones as Associate.

MR. JONES:—I do not know that I can be of any service to the officers of this Section, and I do not know what you intend that I should do, but I do consider it an honor to be appointed as Associate to such worthy gentlemen as Mr. Osseward and Mr. Becker.

MR. NITARDY:—The Associate is the apprentice and the object is that he will become acquainted with every part of the work so that when he becomes Secretary he will make an energetic, hard-working Secretary and later when he becomes Chairman, he will make a hard-working and energetic Chairman.

MR. WILBERT:—I move a hearty vote of thanks to ex-Chairman Nitardy.

Motion approved by rising vote.

Motion to adjourn. Carried.

C. OSSEWARD, Secretary.

---

## ON THE PREPARATION OF FLAKE AGAR-AGAR.

---

F. W. NITARDY, PH. C.

---

Agar-agar has recently come into favor with the medical profession as an evacuant. Its value is based on the formation of a soft, bulky indigestible jelly in the intestines, which, it is claimed, promotes peristalsis by supplying the necessary residue frequently lacking on account of our present-day highly refined foods, and softens the feces by virtue of its water absorbing and holding power.

In its natural form agar-agar is hardly available for this purpose as the long shreds are difficult to administer. The powdered agar-agar, it is claimed, will be digested when taken. Its most desirable form for administration is therefor in flakes, in appearance quite similar to flake breakfast foods and usually prescribed to be eaten with or as such cereals.

A simple and easy method of preparation is as follows:

Soak and rinse a suitable quantity of agar-agar in water, drain well, grind through a meat-chopper and spread out in thin layers on cheese-cloth trays to dry in a dust-free airy place. When dry collect and store in suitable vessels. This product is usually prescribed in doses of one to four heaping teaspoonfuls (1 to 4 gm.).

If it is desired to medicate the agar-agar, the required amount of medicament for each 500 gm. is dissolved in water so as to form 1000 cc. of solution. This solution is mixed with the flake agar-agar and as soon as it is evenly and completely absorbed, the product is again spread out to dry.

## SHORT AND SIMPLE ALCOHOLIC ASSAY METHODS.

JAMES SEYMOUR AND GEORGE MCDERMAND, M. S.

As Professor Havenhill reported so favorably his adoption and success with the "salting out" assay for alcohol, in examining Spirit of Camphor, we extended the same method to estimate alcohol in other alcoholic liquids, including vinous and spirituous liquors. We checked the results by other known alcoholic assay methods and the results seem fairly accurate. The method is quite simple and rapid, only a few minutes usually being required, and no complicated apparatus, a small cylinder graduate (or better, a slender graduated tube), being sufficient. This renders the method useful and practicable for the pharmacist.

The method consists of adding dry potassium carbonate to the sample, (5 cc. or 10 cc.) in a graduate until a little of the solid salt remains undissolved after a minute with shaking. After settling, the oily layer of alcohol is measured and read in percentages. If we have a 10 cc. sample, each cc. of alcohol reads as 10 per cent. etc.

When beer, wine or other solutions containing sugar or viscous substances is tested, it should stand a few hours, as some of the water is suspended with the alcohol and must settle out. The presence of water is shown by the layer of alcohol becoming milky when first separated.

As we have but begun the work we have but few samples to report. Two samples of beer when thus tested:—

No. 1 beer showed.....	8%
2 beer showed.....	10%
1 good whiskey showed.....	50%
1 bar whiskey showed.....	42%
1 gin showed.....	43%
1 wine showed.....	32%

These checked with known accurate assays by other methods except No. 1 beer. Ten cc. samples were taken in the above tests.

For the estimation in Spirit of Camphor, we would refer to the proceedings of the A. Ph. A. of 1907, pp. 443 and 444.

## ASSAY OF TINCTURE OF IODINE.

Test to see if the solvent is official alcohol by adding a little potassium carbonate to a small portion (5 cc.) and shaking. If a lower stratum of water solution is formed it shows a deficiency of alcoholic strength. U. S. P. alcohol gives no lower liquid.

## DETERMINATION OF IODINE AND ALCOHOL.

A 5 cc. sample titrated with a little less than 28 cc. of decinormal sodium thio-sulphate should be decolorized, (by following U. S. P. directions). This colorless solution can now be saturated with potassium carbonate to liberate the alcohol, which rises as an oily layer to the top. The percentage should show between 92 and 94% alcohol. Even with this small sample the error may be too small to vitiate the results, even with the dilution from the decinormal thiosulphate. A more concentrated solution, however, may be used if preferred.

We do not claim anything novel in this method of assay, but wish to call attention to its simplicity, accuracy and rapidity.

## ARTIFICIAL PERFUMES.

---

H. S. Groat.

---

The tendency of the present day on the part of both, the large perfume manufacturers and pharmacists who make their own perfumes, is decidedly toward the manufacture and perfection of artificial goods. The constant increase in price and consequent unreliability in quality of essential oils, has been a main factor for this change, augmented by the rapid advancement of the science of organic chemistry.

Since the active principle of many drugs is now made synthetically almost the entire world's supply of these now comes from the chemical laboratory. The active odoriferous principles of many, if not most, of the essential oils have been isolated and their identity with synthetic organic compounds firmly established. In fact, so extensively has this field been developed that now one can obtain commercially and at much lower figures, the odoriferous principle of almost every known essential oil; consequently perfumes made from these synthetic compounds are much cheaper than the natural perfumes, and in many of the cases are the equal, if not the superior, of the natural product itself.

"Artificial Perfumes" is a very exhaustive and complex subject and so closely allied with advanced organic chemistry that in this brief treatise, I can mention in a limited way only the more important of these synthetic bodies of which the artificial perfumes of the present day are merely mixtures.

*VANILLIN*.—Vanillin is identical with the active ingredient or chief constituent of vanilla, and is extensively used in enhancing natural extracts as well as the chief flavoring agent of artificial vanilla flavorings. Vanillin is methyl protocatechuic aldehyde— $C_6H_3(CO H) (OCH_3)_3 (OH)_4$ . It occurs in white needles and melts at  $81^{\circ} C$ . It has an intensive vanilla odor and is used extensively in confectionery, as well as in perfumery.

*COUMARIN*.—Coumarin is the active principle of the Tonka Bean, and is used extensively as a substitute for it in the manufacture of flavoring extracts. It is a white crystalline solid, melting at  $67^{\circ} C$ . Coumarin is the delta lactone of coumarinic acid— $C_9H_6O_2$ . It is used considerably in perfume manufacture as a fixative for other odors, and is the most important synthetic compound of this class. It is the chief ingredient of *Foin Coupe*, or New Mown Hay Bouquet.

*HELIOTROPIN*.—Heliotropin is a synthetic compound possessing a powerful Heliotrope odor. It is a white, crystalline compound, melting at  $37^{\circ} C$ . Heliotropin is the methylene ether of Protocatechuic aldehyde— $C_6H_3(CHO) (O_2) (CH_2O_4)$ . An alcoholic solution of it makes a very fine Heliotrope perfume, which can be improved by a little vanillin or coumarin for a fixative and intensifier, blended with a little bergamot, lemon or neroli oils.

*AUBEPINE OR HAWTHORNE*.—The concentrated odor of Hawthorne or May blossoms is represented by anisic aldehyde— $C_6H_4(OCH_3) (CHO)_4$ . When properly diluted this makes a very pleasant perfume, which is greatly augmented by blending with a small quantity of citrns oil—orange or petitgrain.

**IONONE.**—Ionone is the concentrated violet odor. In the concentrated form it does not in the least resemble violets, but does when greatly diluted. The commercial product is only a 10% alcoholic solution, because of its great intensity of odor. Ten cubic centimeters of this extract when diluted with pure spirits are sufficient to produce a thousand cubic centimeters of triple extract of violets. The perfume is enhanced by the addition of a little orris oil, which acts chiefly as a fixative. The chemical formula of "Ionone" is kept a trade secret, but it is evident that the several commercial brands now on the market vary chemically; according to Tiemann, they vary from alpha, beta and gamma Irone— $C_{13}H_{20}O$ —to the beta, oxime and alpha ketones of same.

**ARTIFICIAL MUSK.**—For many years attempts have been made to artificially imitate the odor of musk. Not however, upon the basis of any knowledge of the constitution of the natural perfume. The chemistry of natural musk—the preputial secretion of the musk deer, *Moschus Moschiferus*, is entirely unknown. The artificial musk of modern perfumery is tri-nitro-butyl toluene—a white, crystalline solid, melting at  $96^{\circ}C$ . The entire commercial supply has been manufactured under the patents of Albert Bauer until recently, when a rival manufacturing chemist successfully marketed a di-nitro-butyl xylene as an artificial musk. The odoriferous constituent of the musk does not appear until the nitrated hydrocarbon radical has been introduced into the compound. The use of musk is extensive for perfumery of a certain kind, where powerful odors are desired. It is used very extensively in the scenting of toilet soaps, the presence of alkali improving its odor as well as acting as a fixative.

**ARTIFICIAL NEROLI.**—At present there are two artificial neroli substances on the market: one a solid, sold under the name of "Nerolin," the other a liquid called "synthetic Neroli oil." "Nerolin" is beta naphthol Methyl ether, a white crystalline compound, melting at  $70^{\circ}C$ ., first introduced into commerce under the name of "Bromelia." Synthetic neroli oil is a mixture of the alcohol geraniol— $C_{16}H_{18}O$ —and linolol— $C_{16}H_{18}O$ —together with their acetic esters. The characteristic odor, according to Erdmann, is due to the presence of the Methyl ester of anthranillic acid. The artificial neroli oils of commerce are uneven in value, and as their exact composition is a trade secret, the only road open to the practical perfumer is to imitate the natural oil by experimental mixtures of the compounds named.

**ARTIFICIAL LILAC.**—Terpineol— $C_{10}H_{18}OH$ —in dilute form possesses an odor almost identical to that of natural lilacs, though also suggesting elder flowers and hyacinth. Terpineol is the basis of many floral perfumes of this class. A mixture of 90% terpineol and 10% palmarose oil, yielding perfume indistinguishable from the favorite French perfume, *Muguet*. (The term *Muguet* is merely a French equivalent of Lily of the Valley.) In general, lilac extracts, or "white lilac," may be regarded as solutions of terpineol, which are slightly modified by the addition of other perfumes, generally oils of ylang ylang, geranium, sandalwood or rose, according to taste. For perfuming soaps a straight solution of 1% terpineol does very well.

**ARTIFICIAL HYACINTH.** Several of the artificial oils of Hyacinth are on the market which are fairly good imitations of the natural perfume, chief among

them being chlorstyrolene and alpha bromstyrolene. Styryl alcohol— $C_9H_{10}O$ —also known as cinnamyl alcohol, has a powerful odor of hyacinths, while benzyl alcohol— $C_6H_5CH_2OH$ —is an aromatic body of strong hyacinth and bitter almond odor.

*ARTIFICIAL LEMON OIL.*—There are on the market several preparations which bear the label synthetic oil of lemon, (terpenless), and which possess a strong lemon odor. Analysis by Parry and other authorities shows that citral is the chief compound of these preparations. Citral in a diluted state has been strongly recommended as a substitute for lemon oil by the Schimmel Company, who in one of their late annual reports says, "Normal lemon oil contains, on the average, about  $7\frac{1}{2}\%$  of citral. Therefore, 75 grammes of citral would suffice as a substitute for one kilogramme of oil of lemon. As its flavor is somewhat wanting in the degree of freshness characteristic of good lemon oil, this deficiency must be neutralized by an addition of lemon oil." Therefore, citral is now generally used in combination with oil of lemon. The most approved proportion is 100 grammes of citral to 1400 grammes of oil of lemon. This is equivalent in odoriferous strength to three kilogrammes of oil of lemon. We quote farther: "Fifteen grammes of the mixture are sufficient for making one hectoliter of lemon liquor, and this remains clear, even if it contains only 30% alcohol. For making lemon syrup to be used for lemonades, 20 to 25 grammes are sufficient for 100 kilogrammes of syrup. When the use of citral is preferred without the addition of oil of lemon, the following solution deserves the preference: 75 grammes of citral and 925 grammes of alcohol (95%). This equals one kilogramme of oil of lemon in odoriferous power.

*ARTIFICIAL ROSE OIL.*—Although numerous "artificial" and "synthetic" rose oils are listed by various firms, there is nothing which in any way competes with the fine odor of natural otto of roses. The two best defined constituents of oil of rose are the alcohols geraniol— $C_{10}H_{17}OH$ —and citronenello— $C_{10}H_{20}O$ —and these bodies with a trace of their acetic esters will produce as good an "artificial oil of roses" as may be made. A little genuine oil of roses is frequently added to make the substitute a little more passable. A compound patented by Schering, termed di-methyl-heptadinol— $C_9H_{16}O$ —which possesses strong rose odor, has met with commercial success.

*NIOBE OIL.*—The synthetic perfume sold under this name is merely a methyl benzoate— $C_6H_5COOCH_3$ —. It is a liquid having the specific gravity of 1.102, and a boiling point of  $195^\circ C$ .

*BERGAMOIL.*—This body, which is used as a substitute for bergamot oil, and which it resembles very closely, is simply linalyl acetate— $C_{10}H_{17}C_2H_3O_2$ .

*ARTIFICIAL JASMINE OIL.*—The natural jasmine perfume is due to an essential oil, but this is both exceedingly delicate and expensive. The odoriferous principle of jasmine is generally extracted in the form of a pomade. There, however, are several brands of synthetic oil of jasmine on the market, their chemical composition varying greatly. None of them are single compounds, but are mixtures of several odoriferous bodies, which together reproduce very fairly the jasmine perfume.

According to Verley (owner of the French patents for jasmine oil) a mixture

of 10% linalol and 90% phenyl-glyco-methylene-acetal makes an admirable artificial product, as these two chemical compounds are the chief constituents of the natural oil. Other authorities, Hesse and Mueller, deny the existence of phenyl-glyco-methylene-acetal in jasmine oil, or that they even give a jasmine odor. Their conclusion lead us to infer that a fine artificial product results, from a mixture of benzyl acetate, 65% ; linalyl acetate 7 to 10% ; benzyl alcohol, 6% ; linalol 16%. We infer from Parry's experiments that secondary styrolyl acetate— $C_6H_5 \cdot CH(O.COCH_3) \cdot CH_2$ —is in itself a good product. Artificial jasmine oil is made on the basis of these researches, although probably small quantities of some bodies not generally known are added by the manufacturers.

*ARTIFICIAL COGNAC OIL.*—Cognac oil, which is not an essential oil in the fullest sense, is prepared by distilling wine lees with seven or eight times its weight of water. Commercial "oenanthic ether" serves its purpose fully and is a product of more reliable quality than the genuine oil. It is not used so much in the manufacture of artificial perfumes as in the manufacture of brandies, chiefly for flavoring poor qualities of brandies made from corn.

Any intelligent perfumer can produce most all of the natural perfumes from the synthetic bodies of which we have spoken briefly or otherwise. Very finished products can be perfected by the proper and cautious use of the more common aromatic alcohols and esters for correctives, intensifiers and fixatives.

---

## DETERIORATION OF GALENICALS.

---

E. KIMMICH, PH. G.

---

Many of the U. S. P. and N. F. galenical preparations deteriorate after storage for periods varying from a few weeks to several years, and this change in constitution is due to the action of light, changes in temperature, oxygen of the air, the action of living organisms, and the spontaneous breakdown which must take place sooner or later. These changes sometimes alter the physical properties of a preparation to such an extent that it seems like a different product.

Every pharmacist has had his troubles with liquid preparations containing Iron Phosphate and Pyrophosphate; he knows that when such products, (mainly elixirs) are freshly made they are usually of a light amber or pale greenish color; but on aging some turn to a darker green or brown, depending on the solvents or adjuvants used, such as the alkaline citrates, ammonium chloride or acetate, and sodium chloride.

When exposed to light for a much longer period, decomposition and precipitation takes place. While these changes are largely brought about by the action of light and temperature, the solvents and menstrua used have a great deal to do with hastening the process.

Some years ago I made several series of experiments in an effort to determine the principal cause of such changes. These experiments, consisted mostly of the group containing Iron Phosphate Sol., Iron Pyrophosphate Sol., and Tincture

Citrochloride of Iron in combination with Quinine salts, and in menstrua containing varying percentages of alcohol, glycerin, sugar and water, also with added solvents, to aid in the solution of the iron and quinine salts, such as Sodium Citrate, Potassium Citrate, Ammonium Acetate, Ammonium Chloride, and Sodium Chloride.

On exposure to diffused light for several months, and direct sunlight later, I was also able to make the following general deductions:—

(1) Citro-chloride of Iron withstood the effects of light better than the Phosphate and Pyrophosphate of Iron.

(2) The less sugar the product contained the slower the darkening in color.

(3) The varying percentages of alcohol did not seem to have much influence in the matter of discoloration.

(4) Those having Ammonium Chloride or Ammonium Acetate present darkened more quickly than those containing Potassium and Sodium Citrates and Chlorides.

(5) The presence of glycerin retards discoloration and decomposition.

(6) Prolonged exposure to direct sunlight decomposes the mixtures, probably with the formation of insoluble Ferrous Phosphate and Quinine Citrate, which is only slightly soluble.

(7) Storage in amber bottles is almost a necessity, as the changes take place very slowly if light is excluded.

When the light has decomposed the mixtures, in corked bottles, pressure is developed, due to the formation of  $\text{CO}_2$ .

Samples tested at the time for fermentation showed the liquids to be sterile, indicating that bacteria played no part in producing the changes.

In conclusion I would state that elixirs, in which a soluble green iron compound is wanted, will keep better if made with citrochloride of iron, particularly if part of the sugar is replaced with glycerin and the liquid is stored in amber bottles.

Beef, Iron and Wine, N. F. is another product that will sometimes give trouble, especially if put up in flint bottles and exposed to direct sunlight in a display window. The action of the light causes decomposition, forms a gas and possibly blows the cork. As this product contains ingredients that are liable to ferment, one naturally supposes that the product has spoiled from this cause; the real cause, however, is the action of actinic sun rays on the citrochloride of iron present. Ferric Salts in the presence of citric acid are reduced by action of sunlight, and the citric acid is decomposed, liberating  $\text{CO}_2$ .

In making this statement I do not mean to say that Beef, Iron and Wine does not ferment under certain conditions, but that we have the same factor present to cause decomposition that we have in the iron elixirs.

Most pharmacists have observed the darkening in color and change in taste of syrups containing chemicals held in solution by the aid of acids, also syrups containing acids only. In such compounds we can always look for those changes, and the more acid present the more pronounced the color and the more rapidly will the changes take place.

Syrup Hydriodic Acid is a fair illustration. The present U. S. P. syrup contains less sugar than the 1890 formula, and consequently is more stable. Samples that had stood for over ten years, made with varying amounts of sugar, glycerin and water showed the discoloration to be in direct proportion to the amount of

sugar present. One sample made with 60% glycerin and no sugar remained practically unchanged. In none of the samples was the darkening due to free iodine.

Syrup of Iron Iodide is another product requiring the greatest care in manufacturing to prevent darkening at the beginning. If the operator is fortunate enough to make the syrup without its being tinted through exposure or contamination in the process of manufacture, he will find that the syrup soon begins to discolor on aging, even if kept in flint bottles and in the light.

There is enough Hypophosphorous Acid added for the purpose of preventing discoloring to act on the sugar present and develop colored decomposition products.

Liberation of Iodine causes the least of the discoloration in Syrup Iron Iodide. It is oxidation of the Ferrous into Ferric Iron, and the formation of invert sugar and caramel from the action of the acid on the sugar.

Syrups containing Hypophosphites are another class that darken, and the trouble can usually be traced to the mineral acids present. It is a well known fact that the Hypophosphite Syrups form an excellent medium for the growth of fungus. They should be sterilized where practicable. This will retard the development of fungus growth for a long time, especially if the containers are unopened.

Cod Liver Oil Emulsions darken quite rapidly, unless properly handled. Cod Liver Oil is one of the most easily decomposed fats we have, and exposure to air for even a short time darkens the product and makes a decided change in the odor. All Cod Liver Oil Emulsions act practically the same in these respects, regardless of the emulsifying agents used. The only practical way to prevent or retard discoloration is to bottle the emulsions as soon as made in pint bottles or less so that it will be consumed by the patient before it has time to change in color, odor and taste.

Medicated Bongies and Suppositories with a gelatin base undergo changes which result in hardening of the mass and decrease in solubility. The best and most practicable method is to encase them in proper shaped metal collapsible tubes. In this way the mass is protected and remains soluble indefinitely.

#### DISCUSSION.

CHAIRMAN NITARDY:—I think this paper a very valuable one. It treats of a question that has not received sufficient attention among druggists.

MR. RAUBENHEIMER:—I think the subject of this paper one most interesting to every pharmacist. Preparations containing ferric salts should not be exposed to light. They should be kept in amber-colored bottles. The Formulary is very specific about that. On the other hand, ferrous salts ought to be exposed to light. Bear that distinction well in mind. The less sugar there is in these ferric preparations the longer they will keep. They should not contain any sugar. The next official formula for Elixir of Iron, Quinine and Strychnin will not contain any sugar. It will contain glycerin and mostly water. The same applies to syrup hydriodic acid. The more glycerin this preparation contains the longer it will keep. I have some in my store that I made about twenty-seven years ago and it is still white. I think it a fallacy to add hypophosphorus acid to syrup of ferrous iodid. All that is necessary with that,—and I believe that is the old German method,—is to put the syrup in a flint-glass bottle, a pint, quart or gallon bottle, and if you have much use for it put it into a five-gallon demijohn and keep it exposed to light. Drop into it an ordinary iron nail. This will much assist in its preservation.

## A FORMULA FOR A NEW TYPE OF A SALINE ANTISEPTIC SOLUTION.\*

CHARLES H. LA WALL, PH. M.

The number of formulas for antiseptic solutions is legion and the types into which they naturally divide themselves are numerous. They may be acid in reaction and contain about 20 per cent. of alcohol, like the official *Liquor Antisepticus*. or they may be of the alkaline type and contain glycerin, like the *Liquor Antisepticus Alkalinus* of the N. F.

For both of these types new formulas have been proposed by me and there is a third type, recently coming into prominence and attaining quite a degree of popularity, for which I would like to propose a formula also. This is a type which is slightly saline and distinctively alkaline, but which contains no glycerin and no appreciable amount of alcohol. The formula is as follows:

Sodium chloride.....	5	gm.
Sodium borate.....	5	gm.
Sodium bicarbonate.....	10	gm.
Oil of spearmint.....	1	cc.
Oil of eucalyptus.....	0.5	cc.
Menthol.....	0.1	gm.
Alcohol.....	5	cc.
Fluidextract of hydrastis (aqueous).....	2	cc.
Water, q. s. to make.....	1000	cc.

Dissolve the salts in 750 cc. of water. Dissolve the oils and menthol in the alcohol. Mix the alcoholic solution of the oils with 5 gm. of magnesium carbonate and triturate gradually with the aqueous solution of the salts. Filter and add the fluidextract of hydrastis and finally add enough water through the filter to make 1000 cc.

This solution makes an excellent wash for the mouth or nose, either full strength or diluted with water, as preference indicates.

### DISCUSSION.

CHAIRMAN NITARDY:—"I will ask Mr. Hall to discuss this paper."

MR. HALL:—"I regret I have not the sample which I prepared here, to show you. It is a very easy preparation to make and results in a brilliantly clear article, without a trace of opalescence. It is a delightfully fragrant preparation and taken in the mouth, either clear or diluted it makes a very pleasant mouth-wash. Of course the presence of five grams of salt in a thousand c.c. leaves just a little saline taste, that is about half of a normal salt solution. Then the golden-seal gives the preparation just a tinge of color, a very pale lemon-color, but as you see it in a pint or a quart bottle it is a preparation that is very attractive to the eye. It leaves a very pleasant taste in the mouth with that touch of salinity which makes it very palatable. Being flavored with spearmint it is very agreeable to taste."

MR. NITARDY:—"Mr. Hall's description gives us a very clear idea of the preparation, even though he has not brought the sample with him."

MR. GREY:—"I would suggest that Berberine might be used instead of aqueous hydrastis. I understand it is used in the preparation called 'Murine.'"

MR. HALL:—"It is but a small amount that is in the preparation, perhaps it is there simply for the color. There is not enough for any medicinal effect, except upon the sensitive nerves there."

---

\* Read before Section Practical Pharmacy and Dispensing at Detroit Meeting.

## PAYING MORE THAN WAGES.

---

E. BERGER.

---

The final action in selling—the contact between clerk and customer—involves the most troublesome problem in retail merchandising. All the knowledge and skill, money and energy which have gone into the assembling and arrangement of stocks, into window display, advertising and the countless details of store service count for nothing unless the sales-person sums these up and expresses them in courteous, intelligent and interested service to the buyer.

How to make sure of that interest and applied intelligence—how to get the clerk to look at each customer and try to treat each customer as the proprietor himself would, is the crowning task in retailing.

Every means that has been utilized to arouse interest, to awaken desire, to impel action, be it advertising, window display, store environment, or any of the many other factors, are all for one purpose—to bring the customer face to face with the clerk. But if that clerk is not in hearty accord with the store and its interests, if that clerk is indifferent to the store's success, what is the probable result? Approximately forty per cent. of possible sales are lost and at least fifteen per cent. of the sales that are culminated never have a "comeback," that is, the customer is not so impressed or gratified by the treatment and service received that he or she goes back to the store to buy a second time or a whole series of second times.

One way of solving the problem—according to the judgment and experience of hundreds of successful merchants—is profit-sharing.

Profit-sharing with employees not only seems to have solved this problem, but has been found to be triple actioned in its accomplishments. In addition to its primary purpose and success in affiliating employees with a store, profit-sharing has been demonstrated to be a very influential advertising factor and of equal merit in inducing patronage.

The profit-sharing system can be divided into three classes, those who share profits based on individual sales, on department sales and on the general sales of the entire store. No doubt the largest results are obtained by the latter, however, it is doubtful that the average druggist could be induced to go into it to this extent in the beginning. Cooperation among druggists is so successful and the several National Cooperative Druggist enterprises, namely: The United Drug Company (Rexall), The American Druggists' Syndicate, and Tampa-Cuba Cigar Company, have grown so extensively that very few progressive druggists are without the fold of at least one of these beneficial enterprises, some "live wires" have all three of these agencies, and it is on the goods manufactured and sold by these enterprises in which the druggist is financially interested and on which he himself "*shares profits*" that he has been successful in sharing profits with his clerks. The percentage paid clerks on these department sales ranges from 2½ to 5%, on entire store sales usually 1%. This dividend is paid on cash sales only.

I am convinced by the results that I have been shown and have personally observed that profit-sharing is the quickest, the most economical, the surest and most effective method of converting the indifferent, thoughtless employee to a keenly interested, active co-partner in the business.

## A NEW ANTIDOTE FOR CORROSIVE SUBLIMATE POISONING.

WILLIAM A. HALL, PH. B.

With the publicity attending a fatal case of corrosive sublimate poisoning of a Southern banker a few months ago and as usually obtains, following the detailed description of such events in the daily press, a marked increase in the use of that poison for suicidal purposes, the thought must have occurred to many, how best to divert the public attention from this poison and what is an effective antidote.

It is not for us to discuss the *surgical* methods used in a few cases *after* the poison has entered the circulation, but what can be done at the outset in the way of mechanical relief by means of the stomach pump and emesis, the administration of albumen and mucilages or oils to retard the absorption in the stomach and intestines.

These general points will all occur to the good practitioner but he wants something else on which he can rely as an antidote. Studying over these matters, about a year ago, an idea came to me that by using one of the general alkaloidal reagents in reverse manner, we could solve the problem.

Obviously whatever was tried, should be safe in itself, and not make a bad matter worse, and also the employment of medicines beneficial in themselves, even if they failed in attaining the special object desired.

With such limitations I settled on the well-known *Mayers' Reagent* which as you all know, is a solution of *Mercuric Potassium Iodide* a general precipitant of the alkaloids. Selecting *Quinine* as the alkaloid to harness, I considered if we could administer the requisite potassium iodide and quinine in solution, after emptying the stomach, we could fill out *Mayers'* formula and the result would be (Mercuric Chloride—Potassium Iodide—Quinine Salt) insoluble in the acid gastric juice, and, as will be shown later, insoluble in the dilute alkaline intestinal liquids as certainly as we can tell from bottle reactions. While all my work was done in *Grammes*, the results, excepting *Mayers'* formula itself are given in *Grains*—the more popular term.

Mayers' reagent N1—20 is

Mercuric Chloride .....	6.775 grammes
Potassium Iodide .....	25.000 grammes
Distilled water to make 1 Litre.	

(You will notice the  $\text{HgCl}_2$  to KI is about 1 to 3.75)

1 cc. *Mayers'* reagent N1—20 = .006775 Mercuric Chloride, .025 Potassium Iodide, and precipitates (approx) .0056 Quinine, gravimetric factor for alkaloid (average, *Lyons*) .311.

It is stated by authorities (U. S. D.) that Mayers' solution is  $\text{HgI}_2 + 2\text{KI}$  but on the basis of his proportions it would seem to be  $\text{HgI}_2 + 4\text{KI}$ .

and the formula seems to provide a slight excess of potassium iodide

corresponding to

#### MODIFIED MAYERS'.

Mercuric Chloride .....	2. grains
Potass. Iodide .....	4.9 grains
Quin. Muriat .....	4. grains (2.91)

Slower in precipitating the quinine, than Mayers' which in *grains* would call for

#### MAYER.

Mercuric Chloride .....	2. grains
Potass. Iodide .....	7.5 grains
Quin. Muriat .....	4. grains (2.91)

The filtrates in both cases were free from mercury ( $\text{H}_2\text{S}$  or  $\text{K}_2\text{S}$ ). The *modified* Mayer filtrate showed very *slight* test for iodine ( $\text{HNO}_3$ —chloroform). Filtrate from *Mayer* tested a little stronger but still slight.

In both equations however, there is no appreciable solvent action of the potassium iodide in solution on the precipitate which in Mayers' was 6.64 grains

Modified Mayers' 4.00 grains.

Choosing quinine hydrochlorate because of its solubility, the following formula was constructed:

Mercuric Chloride .....	2 grains
Dissolved in $\text{H}_2\text{O}$ .....	2 ounces
Potassium Iodide .....	7.5 grains
Quinine hydrochlorate (large excess) .....	20 grains
Hydrochloric acid 10% .....	55 minims
Dissolved in $\text{H}_2\text{O}$ .....	4 ounces

Mix the two solutions which you observe contain acid to make the whole 2 10 of 1% and filter after two hours on a tared filter. Wash and dry to constant weight on the water bath.

Weight dried precipitate ..... 6.64 grains

Duplicate ..... 6.625 grains

To determine if a small excess of potassium iodide in presence of quinine muriate has an appreciable solvent action on the precipitate trial was made using

Mercuric Chloride .....	1 grain
Potassium Iodide .....	7.5 grain
Quinine Muriate .....	4 grain

Net weight of precipitate dried on water bath to constant weight

.210 gramme = 3.24 grains

which is practically the same proportion and answers the question in the negative.

Filtrate evaporated to dryness in tared dish on water bath 16.4 grains. Using

the gravimetric factor .311 (Lyons) for the *Alkaloid* and calculating the salt from that, the p. p. 6.64 grains=originally 2.54 Qcl.

Residue from filtrate .....	16.4	grains
Deduct KCl (1 mol.) .....	.553	grains
Deduct KI (excess) .....	.15	grains
	<hr/>	<hr/>

	15.697	grains
Add water of crystallization. ....	1.57	grains

20.—17.267=2.733 grains

Two grains Mercuric Chloride then in acid solution was precipitated as an in-

+

soluble mass by (2.54 grs. QHCl+7.5 grs.) Potass. Iodide in aqueous solution.

Calculated from residue of filtrate.....2.733 grs.

Theoretically from above formula.....2.91 grs.

Gm. .200 of the alkaloidal precipitate was rubbed up with 250 cc. 2/10 of 1%  $\text{Na}_2\text{CO}_3$  solution, shaken vigorously at frequent intervals for several hours, filtered and residue on tared filter evaporated to dryness on water bath.

Weight of residue .....Gm. .180

showing the maximum solvent action of the dilute alkali to have been 20 m. g. or less than  $\frac{1}{3}$  grain. As some of the Mercuric Antiseptic tablets on the market contain  $\frac{1}{3}$  of citric acid the action of that acid was considered, in presence of mercuric chloride on albumen solutions and also on the antidote described in this paper.

With the *antidote* no hindrance, but rather a more complete precipitation was noted.

With *albumen* solutions the following reactions were observed:

SOLUTION OF ALBUMEN is precipitated by  $\text{HgCl}_2$  but this is prevented if an appreciable amount of citric acid is previously added to the mercury solution.

Mercuric Chloride+HCl (1%) is precipitated by albumen, insoluble in excess of HCl and practically insoluble in citric acid (large excess.)

Mercuric Chloride+Citric Acid is *not* precipitated by *albumen* except in rather large excess, but on further addition of dilute HCl (1%) a copious precipitate occurs. In case you have added a large excess of albumen there is no mercuric salt in the filtrate ( $\text{H}_2\text{S}$ .)

ALBUMEN (in excess) acidulated with 1% HCl remains clear; but on further addition of 1% Mercuric Chloride solution a heavy precipitate falls. The filtrate shows a faint yellow coloration with  $\text{H}_2\text{S}$  but no p. p. even on standing.

MERCURIC CHLORIDE (1%)+H Cl (1%)=No p. p. On further addition of albumen a heavy precipitate unchanged by adding H Cl in excess.

MERCURIC CHLORIDE+ALBUMEN in excess a light precipitate partially soluble at first in H Cl but precipitating again shortly.

MERCURIC CHLORIDE +CITRIC ACID is not precipitated at first, but by adding ALBUMEN in large excess a precipitate falls and on further addition of H Cl a copious precipitate falls. No mercury in filtrate.

To sum up:—Remove the stomach contents as thoroughly as possible, give plenty white of eggs and remove in the best way, wash out the stomach thoroughly,

then for every two (2) grains of Mercuric Chloride supposed to have been taken, administer the following:

Potassium Iodide .....	7.35 grains
Quinine Hydrochlorate .....	4 grains
Dissolved in water .....	4 ounces

For 10 grains Mercuric Chloride:

Potassium Iodide .....	36.75 grains
Quinine Hydrochlorate .....	20.00 grains
Distilled Water .....	4 ounces
Hydrochloric Acid (10%) .....	m. 45

It forms a precipitate with the Mercuric Chloride, insoluble in dilute acids or alkali carbonates (.2%). While investigating these reactions I found another equation using 4.9 grains potassium iodide would work, but the precipitation is not so rapid or complete, nor does the precipitate separate as quickly, *an important point*.

A solution could be kept on hand ready for use of the formula above, with the addition of H Cl to make it 2 10 of 1%.

The study and analyses of the subject are somewhat intricate and perplexing, especially as to the composition of the precipitate with Mayers' reagent but the results for our purpose seem clear, well defined and simple. The well known chemicals, Quinine Muriate and Potassium Iodide are obtainable at any good drug store and with the proportions given, good results may be expected in accordance with my tests. A notable excess of the *iodide* is to be *avoided*, an excess of quinine does no harm but the proportions given should be followed.

It is to be hoped that these suggestions of the writer will be tried physiologically, and medical men use the results given in this paper to help solve a serious problem.

#### PYORRHOEA CURED BY EMETINE.

It is stated that an ameba has been found in the mouth lesions of subjects suffering from pyorrhoea; Barrett and Smith, of Philadelphia, consider this to be the cause of the disease. The local application of emetine hydrochloride solution is stated to have successfully cured the disease. Bass and Johns, of New Orleans, have confirmed the presence of this ameboid organism in cases of pyorrhoea, which is named *Entamoeba buccalis*. They also find that emetine hydrochloride has a valuable curative action, and prescribe it in the form of hypodermic injections into the arm, in half grain doses, at first once daily for three successive days, then every fourth day, finally every seventh day, until the gums have healed and the teeth again become firm. Local application of the solution should be made simultaneously. *Nat. Drugg.*, 1914, 14, 522.

## General Session

### REPORT OF THE COMMITTEE ON POST OFFICE REGULATIONS FOR THE MAILING OF POISONS.

The appointment of this committee is due to a decision rendered in the United States District Court for the District of Missouri to the effect that the Post Office regulation prohibiting the mailing of poisons or poisonous medicines to others than licensed physicians, surgeons and pharmacists was illegal in that it restricted postal privileges to particular classes of individuals.

The present postal law, which was passed March 4, 1909, deals with the subject of poisons, inflammable materials, dangerous articles, intoxicating liquors, etc., in Section 472, as follows:—

SECTION 472. All kinds of poisons, and all articles and compositions containing poison, and all poisonous animals, insects, and reptiles, and explosives of all kinds, and inflammable materials and infernal machines, and mechanical, chemical or other devices or compositions which may ignite or explode, and all disease germs or scabs, and all other natural or artificial articles, compositions or materials of whatever kind which may kill, or in anywise hurt, harm or injure another, or damage, deface, or otherwise injure the mails or other property, whether sealed as first-class matter or not, are hereby declared to be non-mailable matter, and shall not be conveyed in the mails or delivered from any post office, or station thereof, nor by any letter carriers; but the Postmaster General may permit the transmission in the mails, under such rules and regulations as he shall prescribe as to preparation and packing, of any articles hereinbefore described which are not outwardly or of their own force dangerous or injurious to life, health, or property: Provided, That all spirituous, vinous, malted, fermented, or other intoxicating liquors of any kind are hereby declared to be non-mailable and shall not be deposited in or carried through the mails. Whoever shall knowingly deposit or cause to be deposited for mailing or delivery, or shall knowingly cause to be delivered by mail according to the directions thereon, or at any place at which it is directed to be delivered by the person to whom it is addressed, anything declared by this section to be non-mailable, unless in accordance with the rules and regulations hereby authorized to be prescribed by the Postmaster General, shall be fined not more than one thousand dollars, or imprisoned not more than two years, or both; and whoever shall knowingly deposit or cause to be deposited for mailing or delivery, or shall knowingly cause to be delivered by mail according to the direction thereon, or at any place to which it is directed to be delivered by the person to whom it is addressed, anything declared by this section to be non-mailable, whether transmitted in accordance with the rules and regulations authorized to be prescribed by the Postmaster General or not, with the design, intent, or purpose to kill, or in anywise hurt, harm, or injure another, or damage, deface, or otherwise injure the mails or other property, shall be fined not more than five thousand dollars, or imprisoned not more than ten years, or both.

In elucidation of this law the following regulation was promulgated by the Postmaster General:—

4. Medicines composed in part or wholly of poison or poisons, and anesthetic agents, which are not outwardly or of their own force dangerous or injurious to

life, health, or property, and not in themselves unmailable (see Sections 480 and 497), may be admitted to the mails for transmission in the domestic mails from the manufacturer thereof or dealer therein to licensed physicians, surgeons, pharmacists and dentists, and not otherwise, when inclosed in packages in conformity with the conditions prescribed in Section 496: Provided, That the package bears the label or superscription of the manufacturer of or dealer in the article mailed.

In view of the decision in the case above cited the Postmaster General issued a regulation to take the place of paragraph 4 above, the new paragraph reading as follows:—

4. Medicines and anesthetic agents, which are not outwardly or of their own force dangerous or injurious to life, health, or property, and not in themselves unmailable (see Sections 454 and 480), may be admitted to the mails for transmission in the domestic mails when inclosed in packages in conformity with the conditions prescribed in Section 474: Provided, That the terms "medicines" and "anesthetic agents" shall not be construed to mean poisons. Provided further, That the article mailed bears the label or superscription of the manufacturer thereof, or dealer therein, or of the licensed physician, surgeon, dentist, or veterinarian preparing or prescribing the same.

It will be observed that the revised regulation makes no distinction regarding the purchaser, leaving the purchase open to anyone. The question of what does and what does not constitute a poison in the meaning of the act is not defined either in the act or in the regulation, and when anyone proposes to mail an article the postal authorities decline to make a ruling as to what is meant by the word "poison," leaving the mailer to exercise his own judgment in the construction of the law, and, of course, to take the consequences of any errors of judgment which he may make.

This leaves the matter in a very unsatisfactory condition from the point of view of the legitimate drug trade, members of which are frequently requested to mail medicines containing poisons under circumstances which might possibly render them liable to punishment. In fact, a branch manager of one of our largest pharmaceutical houses was arrested in February of this year on the charge of illegal use of the mails in having shipped 100 heroin tablets by mail to a wholesale dealer in another city. Fortunately, however, this case was not pressed for trial, the charge being dismissed. The matter has been the subject of discussion by the Post Office authorities ever since your committee was appointed and various drafts of regulations have been submitted to the authorities both by members of your committee, by the members of the Drug Trade Conference, by the Drug Trade Section of the New York Board of Trade and Transportation, and others.

#### POSTAL REGULATIONS.

##### *Proposed Amendment—Section 472, Par. 4.*

4. Poisonous substances used for sanitary or medicinal purposes or in the arts and sciences which are not outwardly or of their own force dangerous or injurious to life, health, or property, and not in themselves unmailable (see Sections 454 and 480), may be admitted to the mails for transmission in the domestic mails when inclosed in containers made of metal, wood, papier-mache, or similar material, in such manner as to render impossible the escape of any of the contents: Provided, That the article mailed bears the label or superscription of the manufacturer thereof, or dealer therein, or of the licensed physician, dentist or veterinarian preparing or prescribing the same, and that there be written or

printed on such label and on the outside wrapper of the package the word "Poison" in plain letters in red ink, and also that the name and address of the sender shall appear on the outside wrapper of the package: Provided further, That no preparation of cocaine, its salts or derivatives, or any preparation containing any of them, or any preparation of coca leaves, shall be admitted to the mails: Provided further, That no preparation containing more than one of the following substances in the amount stated, viz.: two grains of opium or its equivalent of an opium preparation, one-fourth of a grain of morphine, one-fourth of a grain of heroin, one grain of codeine, or any salt or derivative of any of them in one fluidounce, or, if a solid or semi-solid preparation, in one avoirdupois ounce, shall be admitted to the mails.

While the proposed regulation is more liberal than the one now in force, it is still open to some objection, both on the ground of inconsistency and of unnecessary hardship. In discussing the matter the Drug Trade Section of the New York Board of Trade and Transportation suggested the use of the following wording:

Medicinal preparations which contain poison in sufficient quantity and form, in combination with other ingredients, to be used exclusively as a curative or remedial substance, and which are not dangerous or injurious to life, safety, health or property, may be admitted to the mails for transmission in the domestic mails when inclosed in packages, in conformity with the conditions prescribed in Section 474; provided, that the article mailed bears the label or superscription of the manufacturer thereof, or dealer therein, or of the licensed physician, pharmacist, dentist or veterinarian preparing or prescribing the same.

The proposed regulation by the authorities is open to the objection that it would restrict the mailing of solid and semi-solid preparations to one ounce, practically regardless of the proportion of poison contained. A small tablet of Brown mixture, containing 3/100 of a grain of opium to the tablet, 274 of which are required to make an avoirdupois ounce, could not be mailed because an ounce contains over eight grains of opium. There are many other preparations which could be barred on the same ground. One suggested substitute for the last clause seems to cover this phase of the dose unit in dry form, at least from the manufacturer's standpoint. This reads as follows:

Provided further, That no preparation containing any one of the following substances in more than the amount stated, viz.: two grains of opium, or its equivalent of an opium preparation, one-fourth of a grain of morphine, one-fourth of a grain of heroin, one grain of codeine or any salt or derivative of any of them in one fluid ounce; or, if in the form of a medicinal tablet, pill or other dosage unit, in twelve such units; or if a solid or semi-solid preparation not in dosage units, in one avoirdupois ounce, shall be admitted to the mails.

It is a matter of gratification to note the attitude which has been taken by the postal authorities in this matter, whose willingness to confer with the drug trade gives us reason to hope that through such conference regulations may be devised which will fill all the varied requirements in the case.

Your committee holds that in construing this law it is highly important to take into consideration the object of the measure as a guide to the probable intent of Congress in passing the law. A consideration of the law of 1909 as a whole conveys the impression that the primary object of Section 472 is to protect the mails and those handling them from possible damage. It is true that the clause relating to intoxicating liquors does not square with this theory as to the object of the law, but the presence of such a regulation is easily understood when we take into consideration the effect which the use of the post office might exert in a nullification of local option laws. If we are right in the assumption that the primary

object of the law is to prevent possible injury to the mails or to those handling the mails it will be seen that the term "poison" should be construed as including only those articles or preparations which are liable to poison persons who handle them. Such a restriction of the term would exclude the large majority of medicaments which consist of or contain substances which are poisonous if taken internally in considerable quantities. The latest information which your committee is able to present is contained in the following letter addressed to the Chairman by the Second Assistant Postmaster General:—

"The receipt is acknowledged of your communication of the 5th instant, concerning the sending of poisons and articles and compositions containing poisons through the mails.

"The Department now has under consideration the question of the advisability of promulgating a regulation admitting these articles to domestic mails. If such a regulation shall be issued I will be pleased to forward a copy to you. Until a final conclusion in the matter is reached this office is not in a position to state the attitude of the Department in the matter."

It will be seen from this letter that the post office authorities themselves are not wholly pleased with the regulations as they now stand, and it will only be a matter of time when new regulations will be issued.

There has apparently been a disposition shown in some quarters to use the postal regulations as a means of suppressing the traffic in habit-forming drugs, though there seems to be no warrant for such a construction of the law. The passage of the Harrison antinarcotic bill, which will probably occur soon, will, fortunately, take care of this traffic in a satisfactory manner and do away with the need for burdening the postal authorities with a duty which is apparently not contemplated in the postal law.

We believe that the work of this committee and of other representatives of the drug trade has been of some use in enabling the Postmaster General to arrive at a clearer understanding of the subject. In view of the fact that matter has been taken up by the Drug Trade Conference and that the members of your committee have already laid their views before the department, we respectfully suggest that the committee be discharged.

#### REPORT OF THE COMMITTEE ON PHARMACEUTICAL NOMENCLATURE.

In view of the disruption of communication incident to the European war the International Pharmaceutical Conference which was to have been held in Berne, on August 8, has been indefinitely postponed. Under existing circumstances we cannot hope for any international coöperation in our efforts to minimize the danger arising from the duplication of names. We can, however, urge all manufacturers of pharmaceutical preparations to exercise the utmost caution in naming new products so as to reduce as much as possible the danger from that cause. The use of certain prefixes has grown to such an extent that even the most tenacious memory can hardly keep track of the preparations bearing them. Among these prefixes are: bio-, eu-, fer-, farm-, glyco-, haema-, hemo-, leci-, radio-, thio-, thymo-, uro-, uri-, val-, etc.

But aside from these names, which have merely one syllable in common, there are a vast number of new remedies being launched every year the proprietors of which do not seem to take the trouble to avoid exact duplication of names. We not only have identical names for wholly dissimilar preparations, but also have a number of names which resemble each other so closely either in sound or spelling that confusion is very apt to occur. Below we give a list of some striking instances of this character:—

Absorbine,	(1) a mercurial salve.
	(2) an embrocation consisting of ethereal oils and alcohols.
Acetal,	(1) a hypnotic remedy.
	(2) a liniment for headache.
Amol,	(1) an embrocation.
	(2) a moth preventative.
Borol,	(1) an antiseptic.
	(2) a cough syrup.
Cascarin,	(1) the active principle of cascara sagrada.
Cascarine,	(2) are pills made by Leprince, Paris.
Cascarino,	(3) a tea for the treatment of obesity.
Citrol,	(1) a laxative.
	(2) a photographic developer.
Dormol,	(1) a cathartic.
Dormal,	(2) a hypnotic.
Dormiol,	(1) a preservative for wood.
	(2) a hypnotic.
Energin,	(1) a chocolate preparation of Cod liver oil.
	(2) an albuminous nutriment.
Gallin,	(1) a remedy against gallstones.
	(2) a serum against cholera of fowl.
Guaiaform,	(1) a condensation product of guaiacol and formaldehyd.
	(2) a syrup containing guaiacol-sulphonate and bromoform.
Kreosal,	(1) an internal remedy.
Kreosol,	(2) an external application.
Lactal,	(1) a solution of aluminum lactate.
Lactol,	(2) an intestinal antiseptic.
Monol,	(1) a disinfectant for drinking water.
	(2) a photographic developer.
Navigo,	(1) a meat extract.
Navigol,	(2) a remedy for seasickness.
Nephretin,	(1)
Nephritin,	(2) two subrenal preparations of different origin.
Ozonur,	(1) a serum.
	(2) a nervine.
	(3) a dentrifice.
Salacetol,	(1) a remedy in intestinal disorders.
Salactol,	(2) an injection against diphtheria.
Sulfosol,	(1) a remedy in syphilis.
Sulfosot,	(2) a remedy in tuberculosis.

In view of the conditions which are likely to obtain in Europe for the next year your committee deems it improbable that any international coöperation can be obtained in any direction and therefore respectfully requests that your committee be discharged.

## REPORT OF THE COMMITTEE ON EDITING RULES.

Your committee begs leave to make a *pro forma* report of progress and to request that the committee be discharged. It seems to be impossible to devise general rules of editing which will be accepted throughout pharmacy save as to nomenclature, and in this direction the decisions of the committee on revisions furnish a guide not only for the nomenclature of pharmacopœial preparations, but also as a guide for other names by analogy. Respectfully,

CASWELL A. MAYO, Chairman.

---

ANTISEPTICS IN WAR.

Wounds should receive efficient disinfectant treatment as soon as possible after their infliction, and they should not be treated only by the application of an antiseptic dressing. The double cyanide of zinc and mercury in powder form is useless on the field, where wind and rain prevent it from reaching the wounds. When made into a paste, however, with 1 in 20 carbolic acid (presumably in water) it has been used with complete success. The wounds, says the author, healed beneath a mixture of paste and blood clots, and were beautiful to see. The dye with which the powder is stained acts as a mordant, and by it the chemicals are more firmly fixed in the tissues. This paste can be kept in collapsible tubes without deterioration; in fact, some which has been kept in this way since the South African War remains of the same consistence to-day, while the metal of the tubes has not been affected by the contained chemical. Regret is expressed at the fact that our troops are being supplied with iodine solution as a disinfectant. Many wounds, says the author, has arrived in this country in a disgraceful condition after the early application of iodine, and he thinks that the substance has proved a failure in treating large wounds. A better solution than iodine is a mixture of 1 in 20 carbolic acid and 1 in 500 mercury perchloride in absolute alcohol, colored with rosaline. The carbolic acid is a solvent of fat as well as a germicide; mercuric chloride is a most powerful germicide, while the rosaline, acting as a mordant, fixes the mercuric chloride for weeks after application of the solution. The alcohol encourages penetration of the antiseptic, and does not macerate the tissues like water. The liquid has been applied frequently and freely to large granulating wounds without ill effects. This would be better for the soldier to carry than iodine. It is absolutely non-irritating, and can be safely applied to the scrotum, eyelid, and other parts liable to show the results of irritants. Hydrogen peroxide as a constant application to wounds is objected to on the ground that the granulation tissue under its influence becomes anæmic and swollen, though it may have its uses in removing blood clot and sloughs. G. L. Cheade, C.V.O., C.B., F.R.C. S. (*Brit. Med. Journ.*, December 12, 1914, 1,006).

## Scientific Section

Papers Presented at the Sixty-Second Annual Convention

### THE PHARMACOGNOSY OF THE MEDICINAL RHAMNUS BARKS.

E. N. GATHERCOAL, PH. G.  
(Continued from page 75.)

#### THE PLANT CHARACTERS.

All of the RHAMNUS plants that have been mentioned, are shrubs or small trees, though some are inclined to be procumbent. They have simple, mostly alternate, petioled leaves, usually thin, bright green and glossy, at least on the upper surface, and rather prominently veined. The flowers are small, axillary, usually in small clusters and greenish. The parts of the flower are in fours or fives, though the petals may be absent and the ovary is but one. The flowers are sometimes diœcious, and upon this character these RHAMNUS species seem to fall into two classes, possessing, also, other distinct botanical characteristics, which extend even to the bark and thus cause the bark-drugs derived from the plants to form two rather distinct classes.

In the first division are *Rhamnus catharticus*, *Rhamnus tinctorius* (*chlorophorus*) and *Rhamnus croccus*. These are characterized, for instance, by being rather small shrubs, thorny, with leaves not over 2 or 3 inches long, the flowers diœcious and the parts in fours, the bark thin, the cork purple or blackish in color, the bast bundles very prominent and loose on the inner surface of the dried bark and the bark free from stone cells.

The other group of these RHAMNI includes the species *purshiana*, *californica*, *caroliniana* and *wightii*. These plants are tree-like or large shrubs, non-thorny, with leaves more than 2 or 3 inches long, the flowers perfect and the parts in fives, the bark mostly rather thick, the cork red-brown in color, the inner surface of the dried bark nearly smooth and the bark containing many groups of stone cells.

It is to be noted that *Rhamnus frangula*, included in neither group, corresponds in its botanical features with the second group, but its bark characteristics are like those of group one.

*Rhamnus catharticus*.—A spreading shrub, 6 to 10 feet high, though rarely up to 20 feet high, the ends of the twigs usually forming into stout spines. Leaves are up to 2½ inches long, but mostly less than 2 inches, broadly ovate or elliptical, rather acute at apex and obtuse at base, finely serrate, smooth and of thin texture. The veins are prominent on under surface, the laterals, 3 or 4 pairs, inclined to branch from lower half of midrib. The flowers are diœcious, 3 or 4 in an axil, on peduncles, the calyx-tube with 4 small teeth, the 4 petals narrow and scale-like.

The fruit is globose, lobed by 4 delicate longitudinal grooves, with 3 or 4 seeds, each deeply grooved.

*Rhamnus tinctorius (chlorophorus)*:—The following is Decaisne's description: Twigs, cylindrical, ash gray, terminating in spines and scattered short hairs; leaves 3 to 5 cm. long, 2 to 3 cm. wide, alternate-opposite, short petiolate, ovate, acuminate, base cuneate, denticulate, glabrous above, pubescent beneath, nerves of leaf depressed on upper surface, prominent on lower surface; stipules linear, stiff hair-like, membranous; flowers (male) in twos or fours in the axils; calyx tube infundibuliform, cut into lanceolate, reflex, barely pubescent pieces; petals obovate, membranaceous; stamens not quite equal in height; ovary abortive; style divided, obtuse; berries small nuts obovoid or rounded, slightly furrowed below, shiny.

*Rhamnus croceus*:—Is shrubby, low and branching with spiny twigs and yellow wood. Leaves  $\frac{1}{2}$  inch long, roundish-obovate, toothed, coriaceous, evergreen, nearly glabrous, when dry bright yellow-brown beneath. Flowers on short pedicels, 2 to 6 in the axils, dioecious, apetalous, sepal teeth and stamens four, ovary one, 2-celled; fruit yellowish, greenish and, when ripe, red, small obovate, usually, by abortion, 1-seeded; seed with a longitudinal furrow on one side.

*Rhamnus purshiana*:—Usually tree-like, averaging 15 to 20 feet high, but sometimes attaining a height of 40 feet with a trunk 18 inches in diameter. Leaves up to 7 inches long, broadly elliptic, apex obtuse, finely serrate, very thin, somewhat pubescent beneath and with prominent, evenly-spaced straight lateral veins. The flowers are in axillary clusters, the parts in fives. The fruit is 3-lobed and 3-seeded.

*Rhamnus californica*:—Shrubby, sometimes procumbent, again tree-like. It averages 15 feet high, though attaining a maximum of 30 feet. Leaves up to 3 or 4 inches long, oblong or obovate, obtuse apex, entire or finely serrate, rather thick, glabrous above, usually pubescent beneath. The flowers and fruit are like those of *Rhamnus purshiana*, though the fruit is usually 2-seeded.

*Rhamnus caroliniana*:—A shrub or small tree, with broadly elliptic leaves, 2 to 6 inches long, 1 to 2½ inches wide, acute obscurely serrate, smooth, slightly pubescent on the veins beneath. Flowers in axillary, peduncled umbels or occasionally solitary, the parts in fives. Fruit is globular, smooth, sweet, 3-seeded.

*Rhamnus leptophylla*:—A shrub or small tree 9 to 12 feet high. The leaves are 3 to 5 inches long, 1 to 2 inches wide, elliptical or ovate, sharply acute, finely serrate,

(Detail of cut on succeeding page.)

#### RHAMNUS PURSHIANA BARK

Fig. 1. Transverse section of bark just below terminal bud. A, outer bark; B, middle bark; C, inner bark; 1, epidermis with raised tomentum; 2, phellogen layer (cork does not develop until the middle of first summer); 3, outer parenchyma developing into collenchyma; 4, inner parenchyma containing chlorogenic mucilage sacs; 5, 6, living cells compressed and with living contents; 7, intercellular space filled with mucilage; 8, 9, the aggregate of calcium oxalate (these are abundant in the parenchyma of the middle bark); 10, outer layer of angular elongated cells, the developing primary bast; 11, primary phloem; 12, medullary ray of the bark; 13, developing cambium. (X 600, reduced  $\frac{1}{2}$ .)

Fig. 2. Longitudinal radial section from just below the terminal bud. Letters and numbers as under Fig. 1. The pores in the walls of the parenchyma cells and the living cells of the mucilage sacs are very evident. (X 600, reduced  $\frac{1}{2}$ .)

Figs. 3 and 4a. Two mucilage sacs from the path just below terminal bud. The living cells are but slightly compressed, have no pores evident in the wall and contain living contents. (X 600, reduced  $\frac{1}{2}$ .)

Fig. 4b. Transverse section of outer bark from a 4 year old stem. 1, epidermis with a thick cuticle; 2, cork with brownish wall; 3, phellogen; 4, parenchyma of middle bark. (X 600, reduced  $\frac{1}{2}$ .)

Fig. 5. Transverse section of inner bark from a 4 year old stem. 1, secondary bast with crystal fibers; 2, medullary ray; 3, phloem; 4, cambium. (X 600, reduced  $\frac{1}{2}$ .)

smooth. Flowers are greenish-white, in axillary clusters, calyx 5-toothed, petals 5, stamens 5, stigmas 3. Fruit ovoid, 3-seeded.

*Rhamnus frangula*:—A spreading shrub, non-thorny, 6 to 15 feet or at the extreme 20 feet high. Leaves 1 to 3 inches long, broadly oval or ovate, obtuse, entire, smooth above, somewhat pubescent below. The veins are prominent on the lower surface, the laterals numerous, straight and coming off at regular intervals along the midrib. Flowers, from May to September are perfect, small, whitish, 2 or 3 in each axil, the parts in fives. Fruit green, then red and when fully ripe blackish, is globular, the size of a large currant, smooth, though with 2 or sometimes 3 slight longitudinal grooves and usually 2-seeded.

#### EXTERNAL APPEARANCE OF THE DRUG.

It is to be noted that the bark from any tree or shrub usually presents wide differences in appearance, according to the age of the stem from which it is taken. This fact holds true of the bark-drugs derived from the RHAMNI under consideration and, though in the collection of the bark for the commercial drug, some effort is made to keep the article fairly uniform in appearance yet an admixture of bark from older and younger stems is common.

These RHAMNUS barks fall into the same groups as were noted under the botanical description of the plants. Thus the barks from *Rhamnus catharticus*, *Rhamnus tinctorius* (*chlorophorus*), *Rhamnus croceus* and *Rhamnus frangula* fall into one division, characterized particularly by the relative thinness of the bark, the fibrous fracture and tough, stringy bast bundles and the absence of stone cells from the middle bark. In the other group comprising the barks of *Rhamnus purshiana*, *Rhamnus californica*, *Rhamnus caroliniana* and *Rhamnus weightii* the barks are thicker, slightly fibrous in fracture with little external evidence of bast bundles and possess many stone cells.

All of these barks have some features in common. Thus, they all occur in quills and curved pieces, the thinner barks from the young stems being more inclined to quill and the thicker bark remaining in more or less curved pieces. On all of these barks, lenticels occur after the stem is one or two years old, but these may be more or less obliterated by the increased growth of cork or be covered by lichens which are present to a more or less extent. The color of the inner surface of the barks darkens with age. When freshly gathered, this color is usually a cream or very light-brown, but upon drying and aging may change to a dark seal-brown or almost black. The odor is slight, the taste rather mildly bitter, acrid and astringent.

*Rhamnus frangula Bark*:—(The description is made from various lots of the commercial drug purchased from drug dealers.)

In single or double quills, very seldom in curved pieces, up to .5 M. in length and 3 cm. in diameter, often crushed and flattened. The bark is seldom more than 1 mm. thick, though it may reach 2 mm. in thickness. The outer surface is a dark greenish- or brownish-purple, sometimes almost black, modified by grayish lenticels and lichens. The lenticels, usually abundant, regularly arranged and conspicuous, are transversely elongated up to 5 mm. and of a light gray or grayish-brown color. The lichens are whitish, fairly abundant, but rather inconspicuous. Some longitudinal wrinkles may be present. On bark from the older

stems, there may be considerable roughened, fissured brownish cork. The inner surface is marked by fine striations and occasionally loosened bast and varies in color from a light cinnamon to a dark seal-brown. It fractures easily, rather abruptly and unevenly and shows projecting fibers, fine and short in young bark, sometimes longer and coarser in older bark but in this feature frangula bark differs markedly from the other members of this group. Odor slight, taste mildly bitter, astringent and acrid.

*Rhamnus catharticus Bark*:—(From samples received from Professor William Mansfield of New York, the Missouri Botanical Gardens of St. Louis, and from shrubs in the South Parks of Chicago and in the author's gardens in Oak Park.)

In quills and curved pieces up to .5 M. in length and 2 cm. in width, the bark up to 2 mm. in thickness. The outer surface is black, sometimes with a brownish tinge and with occasional grayish lichens. The lenticels are rather few, small, rounded or somewhat elongated transversely, irregularly scattered and very dark-brown or almost black in color. On pieces from older stems the cork is transversely cracked and inclined to peel transversely in thin flakes. The inner surface is marked by fine striations and by many loosened bast strands so that it often appears very hairy. The color is of various shades of brown, the bast bundles nearly white. Odor is slightly aromatic, the taste bitter and acrid. It fractures easily and evenly except for the projecting bast bundles which may form a fine white "brush" an inch in length.

*Rhamnus chlorophorus (tinctorius) Bark*:—(From a specimen exhibited in a collection of rare drugs at the World's Columbian Exposition in 1893.)

Long, narrow, curved strips, often with some wood attached, the bark seldom more than 2 mm. in thickness. The external color is more inclined to purple than red, but modified by grayish lichens, red-brown transverse lenticels, rough, blackish cork, etc. The inner surface is like that of *Rhamnus catharticus* bark but more exaggerated. The base color of the inner surface is very dark brown, with the numerous light yellow bast strands easily breaking away and projecting as long threads. Upon fracturing, the inner bark becomes lamellated and the bast strands easily separate from the other tissues. The odor and taste correspond to those of the other *Rhamnus* barks.

*Rhamnus croceus Bark*:—(From specimens in the College Museum and received from Mr. Theodore Payne of Los Angeles, Calif.)

In thin quills and curved pieces, up to 3 or 4 mm. thick. Outer surface grayish to dark-brown with a marked red tinge where the outer layers are scraped away. The lichens are abundant, whitish and grayish and some bear brownish apothecia. Lenticels are inconspicuous. The inner surface is dark-brown with more or less light-yellow longitudinal lines or loose projecting bast strands. The fracture is short and even in the outer layers but exposing numerous short projecting bast bundles in the inner layer. The inner bark flakes off rather easily, exposing layer after layer of these tough interlacing strands of bast. The odor is slight but distinctly aromatic and the taste slightly bitter and rather pungent.

*Rhamnus carniolica Bark*:—(From a specimen received from Professor Henry Kraemer, Philadelphia.)

In quills or curved strips, the bark 1 to 3 mm. thick. The outer surface is dark

red-brown modified by many grayish lichens and numerous, rather obscure, irregular, light-brown lenticels, 1 to 2 mm. long. Some longitudinal wrinkles may be seen. The inner surface is grayish to dark-brown and striate. The fracture is short-fibrous, the fibers projecting .5 to 1 cm. from the inner bark. Odor slight; taste bitter and astringent.

*Rhamnus purshiana* Bark:—Commercial Cascara bark is seldom in quills, usually in pieces more or less curved or nearly flat, 5 to 10 cm. long and proportionately quite broad. The bark is seldom less than 1 mm. thick, usually 2 or 3 mm., but up to even 8 mm. thick. The basic color of the outer surface is red-brown but it is often so completely covered with dense whitish lichens that small pieces may be entirely white or grayish. Lenticels are present, transversely elongated and light brown, but, where the lichens are abundant, are inconspicuous. The lichens often show black or brownish apothecia. Adhering mosses are occasionally found and on the thicker pieces roughly fissured cork is present. The inner surface is finely striate and varies from a light yellow-brown to a dark- or purplish-brown. The fracture is quite abrupt, fairly even, though fine projecting fibers can be seen on the fractured surface. It has only a slight odor but a distinctly bitter, acrid and disagreeable taste.

*Rhamnus californica* Bark:—(Samples from Dr. Albert Schneider of San Francisco, and Mr. Theodore Payne of Los Angeles, California.)

In quills, curved and flat pieces, the bark rather thinner than Cascara bark. The natural color of the outer surface is a dull grayish red-brown exhibiting rather numerous but small and inconspicuous light-brown lenticels. Most of the bark is covered with grayish lichens, evenly distributed. These are often roughened and dull, rather than silvery as on cascara. The black apothecia are numerous. The inner portion of the cork is a bright reddish-brown. The inner surface of the bark varies from a light to a dark brown and is smooth or finely striate. The fracture, odor and taste are as those of Cascara bark.

*Rhamnus leptothii* Bark:—(Specimens from O. A. Farwell, Detroit.)

In single quills or curved pieces of varying thickness, color and markings, according to the age of the stem from which it is collected. From young stems the bark is seldom more than 1 mm. thick, of a brown color, more or less covered with grayish lichens, or reddish brown where the outer layer is scraped off so as to

(Detail of cut on succeeding page.)

expose the middle layer. Older bark is 2 or 3 mm. in thickness with grayish or whitish lichens and numerous corky lenticels. Bark from old stems is thicker and more or less rugged from numerous, deep, transverse or irregular cracks in the cork and of a dark brown color. The inner surface is dark brown, the color deepening with exposure in air to almost black. The fracture of the outer portion is short but of the inner layer fibrous and tough. It has a slightly aromatic odor and a somewhat astringent, bitter taste.

#### HISTOLOGY OF THE DRUGS.

The RHAMNUS barks present, histologically, many common features. They each exhibit an outer bark of cork tissue, a middle bark of parenchyma tissue bearing chlorophyll and an inner bark containing in addition to the phloem strands and medullary rays, strands of bast.

The chief histological distinction between these barks lies in the presence or absence of stone cells in the middle bark, and this distinction forms the same groups that have already been twice mentioned: viz: one group embracing the bark from the species *catharticus*, *tinctorius* (*chlorophorus*), *croceus* and *frangula* in which stone cells are absent and the group including the barks from the species *purshiana*, *californica*, *caroliniana* and *wrightii* in which stone cells are present.

*Rhamnus purshiana* bark has been selected for the type-study and its structure is described in detail. The descriptions of the other barks bring out especially the points of distinction from Cascara bark.

*Rhamnus purshiana* Bark:—The fresh material used for these sections is from shrubs supplied by the U. S. Dept. of Agriculture and grown in Oak Park, Ill., and from specimens sent from the Missouri Botanical Gardens at St. Louis, Mo.

In a transverse section, cut from just beneath the terminal bud, from a stem collected in late fall, the bark measures about 0.4 mm. in thickness on each side of the stem, which was about 2 mm. in diameter. It is easily differentiated into an outer, middle and inner bark.

The outer bark (Figs. 1 and 2) consists of a row of epidermal cells, 15 to 20 microns in diameter, nearly cubical (square in both transverse and longitudinal sections), with thin inner and side walls and an outer wall thickened to 5 microns and cutinized. The lumen is filled with dark-brown contents. The epidermis bears many curved, pointed, unicellular trichomes up to 20 microns in thickness and 2 mm. long. Their walls are cutinized and form about two-thirds the diameter at the base of the trichome. The trichomes are even more abundant on the scales of the bud.

The middle bark (Figs. 1 and 2) consists of an outer layer of parenchyma cells somewhat elongated tangentially, with cytoplasm and nucleus and somewhat thickened, pored, cellulose walls. Then follows typical rounded parenchyma cells surrounding numerous tubular mucilage-sacs, the largest of which are 0.2 mm. across. The lumen of these sacs is bordered by thin-walled cells elongated tangentially (to the sac) and compressed radially (Fig. 1). These cells are, in fact, nearly cylindrical, for their diameter longitudinally (Fig. 2) is usually no greater than the radial diameter. These mucilage-sacs are apparently of schizogenic origin.

A study of the pith, where these secretion-sacs are also abundant, affords still further support of the view that these sacs are of schizogenic origin. Thus, as shown in Fig. 3, there are five cells, broad and thin-walled, with living contents surrounding an intercellular space containing mucilage. Fig. 3a represents a more mature secretion sac and shows the lining cells somewhat compressed but yet with living contents and thin, non-porous cellulose walls. Fig. 6 indicates a mature secretion-vessel from the pith in transverse section. It is 180 microns across, bordered by cylindrical cells elongated tangentially (to the vessel) to a maximum length of 135 microns, a width radially of 10 to 20 microns and a depth (as seen in Fig. 7), nearly the same. These cells possess simple, oval pores connecting one cell with another and with the adjoining pith parenchyma. In Fig. 7, a view of one side of one of these secretion-sacs in the pith cut longitudinally 10 mm. below the terminal bud, the secretion-cells show the wall facing the lumen of the vessel to be very thin and without pores, but the walls adjacent to the pith parenchyma to be thicker and to possess pores. The walls of both secretion- and parenchyma-cells are slightly lignified. The maximum length of these secretion-sacs is 0.7 mm., but in all observed, the ends were not bordered with secretion-cells, indicating possibly that the vessels were curved and longer than above stated. The mucilage stains with methylene blue, as does that of *Althaea* and *Ulmus* and in sections cut and kept in a small amount of water the fluid becomes quite sticky and stringy. The mucilage-sacs, both in the bark and pith, are present in abundance only for a short distance from the terminal bud. They are abundant in the bark, however, for a distance of several mm. about each lateral bud. Evidently the mucilage is stored for the use of the buds in their early spring development.

A few rosette aggregates of calcium oxalate (Figs. 1 and 9), 15 to 45 microns in diameter are found in the middle bark as also in the pith in this section.

The inner bark (Figs. 1 and 2) contains an almost continuous outer layer of cells, rounded, and from 5 to 10 microns wide, in transverse sections, but already elongated and with overlapping, pointed ends in longitudinal section. Their walls are of cellulose, somewhat thickened and they contain cytoplasm and nucleus. This is the developing primary bast. The inner layer of the inner bark is the primary phloem consisting of very small thin-walled cells with living contents. Sieve-tubes cannot be differentiated. The cambium is beginning to form. The wood circle, while very narrow, yet contains many xylem masses rather evenly spaced with two or three or several rows of parenchyma between them. Each mass contains from 1 to 10 very small spiral tracheal tubes.

In a transverse section cut from the stem, 2 mm. below the terminal bud, it was observed that the outer wall of the epidermis was much thickened, up to 10 microns thick; that the mucilage-sacs of the middle bark were somewhat larger, the lining cells being more compressed radially and elongated tangentially; that the primary bast cells had somewhat thickened their walls and were becoming angular in shape; that the cambium was well formed, had added several tracheal tubes to each xylem mass and had increased the amount of phloem. Large rosette aggregates were very abundant in middle bark and pith. The formation of crystals in the secondary phloem was also noted. Medullary rays between the xylem masses and extending into the phloem were easily differentiated.

In sections cut from the same stem, 15 mm. below the terminal bud, it was noted that the outer wall of the epidermis had further thickened and was now fully 15 microns wide. The mucilage-sacs were few. The outer parenchyma of the middle bark had very much thickened its cell walls with cellulose, in fact resembled collenchyma. Primary bast had further thickened its walls which still remain cellulose. The cambium had developed much xylem, the wood circle being now 2.5 mm. in thickness. The medullary rays were distinct, filled with starch, the grains being 4 to 6 microns wide.

At 20 cm. from the terminal bud the first development of cork was noted, otherwise the stem showed little change except a large growth of wood. At about 25 cm. from the bud the first lignified secondary bast was seen and at 30 cm. the formation of stone cells from parenchyma cells of the middle bark had begun.

A description of sections of the stem at 30 cm. from the terminal bud is as follows:—

Total diameter of stem 7 mm., of which the bark is 0.6 mm. on each side.

The outer bark (Fig. 8) consists of six rows of cork cells from 15 to 30 microns tangentially, 10 to 15 microns radially and the same longitudinally. In transverse and longitudinal sections they are 4-sided and arranged in radial rows. The walls are thin, suberized and brownish in color. Some of the cells appear to be filled with a homogenous brown mass.

Middle bark (Fig. 9). The outer collenchyma has undergone no change. Its cells are from 15 to 45 microns tangentially, 10 to 15 microns radially and 30 to 60 microns longitudinally. Their walls of cellulose are from 3 to 8 microns in thickness; the contents are cytoplasm and nucleus and dark brown in color. The inner layer of the middle bark consists of parenchyma 15 to 30 microns tangentially and longitudinally, 10 to 15 microns radially, the cellulose walls 3 or 4 microns in thickness with elongated oval or angular pores. The contents are similar to those of the collenchyma. Mucilage-sacs, except near lateral buds, are practically absent.

The stone cells develop from the parenchyma of the middle bark apparently by a thickening and lignification of the walls. No characteristics in any of the parenchyma cells could be found to indicate they would become stone cells until the first sign of lignification occurred. In Fig. 9, *b* indicates a cell with walls no thicker than the adjoining parenchyma cells, but it shows pores more plainly and it has begun to lignify. Usually but one or two parenchyma cells at a spot show

(Detail of cut on succeeding page.)

Fig 22

these first signs of change but neighboring cells follow until they form a group of stone cells varying in size but usually not larger than 4 cells radially, 20 cells tangentially and 10 cells longitudinally. The first section showing stone cells contained but the one small group, but the number of groups rapidly increased from this point on.

There are formed at this time in some of the parenchyma cells adjoining the stone cell group, small prismatic crystals of calcium oxalate, seldom exceeding 15 microns in greatest diameter and usually not more than 8 or 10 microns. One or more of the crystals may occur in a cell. If more than one occur, they are separated by a delicate septum or septa of cellulose. The slight enlargement of the parenchyma cells, when forming into stone cells, tends to compress the surrounding parenchyma and causes the stone cells to be angular or irregular in shape. Usually their greatest diameter is tangentially and seldom exceeds 60 microns. They mostly are from 30 to 45 microns, some as small as 15 microns in diameter. The walls are thickened sometimes almost to the extinguishment of the lumen (Fig. 14), again the lumen may occupy one-third the total diameter (Figs. 16 and 17). Pores are prominent and stratifications may be distinguished.

Inner bark (Fig. 10). This is still very narrow, hardly more than 100 microns wide. The primary bast (Fig. 9), in small scattered bundles, the fibers with thick cellulose walls, may be seen at the outer edge of the inner bark. The phloem presents nothing new.

The secondary bast, first observed about 5 cm. higher up in the stem, is now seen to be present in small bundles of 2 to 24 fibers, 30 bundles in a single row being present in this transverse section. The bast fibers seldom exceed 15 microns in diameter, nor more than 0.8 mm. in length. They are circular or somewhat angular in transverse section and in longitudinal view fiber-like with slenderly tapering ends (Fig. 11). The lumen is seldom more than one-fifth the total diameter. The walls are partially lignified, the cell contents nearly gone.

Crystal fibers are found adjacent to the bast bundles (Fig. 11). One bundle of bast in transverse section containing 13 bast fibers had adjacent to it 13 crystal fibers, another bundle of 8 bast fibers had 8 crystal fibers about it, another of 6 bast fibers had 4 crystal fibers, another of 8 bast fibers had 2 crystal fibers, one of 16 bast fibers had 9 crystal fibers about it and one of 16 bast fibers had 16 crystal fibers. It could not be established that the number of crystal fibers corresponds with the number of bast fibers in the bundle, though according to my observations the crystal fibers never exceed in number the bast fibers. While sometimes there is but one tangential row of bast fibers in a bundle, they often are arranged in 2 or 3 or even 4 rows. The crystal fibers, though sometimes 15 to 20 microns in width, are usually less than that. They average almost the same width as do the bast fibers. While it is usually difficult to obtain their length, yet in two or three instances they were clearly shown to exceed 300 microns in length and they probably closely approximate the bast fibers in length. They are inclined to be angular in transverse section, usually 4-sided, and fiber-shape longitudinally, with pointed ends, though often not so pointed as the bast fibers. The walls are thin, about the same as the surrounding phloem cells, 1 to 2 microns thick. The

crystals they contain are mostly prisms of calcium oxalate arranged in a single row occupying nearly the width and length of the lumen. They are largest and best-formed at the middle of the fiber and become smaller and more irregular toward the ends, where they are very small. In some fibers rosettes are associated with the prismatic crystals. The number of crystals in a fiber is often 30 or 40. The crystals are rhombohedrons, each of the six faces being nearly equal in size and shape, the acute angles being of about 60 degrees. Their diameter seldom exceeds 15 microns, the smallest being about 5 microns. In the more mature fibers the crystals are separated by septa of cellulose. These septa form with the development of the fiber and the formation of the crystals, but are difficult to distinguish until after the fiber matures. Then the wall adjacent to the bast and the side walls, as also the septa, become lignified. The outer wall was never found to be lignified, but in older bark or in the powdered drug was often broken away, leaving the lignified septa projecting from the inner thickened lignified wall (Fig. 22).

The phloem also contains longitudinal rows of rosette aggregates of calcium oxalate (Fig. 11), though these usually are not adjacent to the bundles of bast. These crystals are apparently produced in the elongated cells of the cambium, 3 or 4 to 20 or 30 crystals in a cell, but from the time crystals begin to form delicate septa begin to show between them (Fig. 12). With the enlargement of the cell and of the crystals and the increased thickness of the septa, the whole takes on the appearance of a row of rounded parenchyma cells each containing a rosette aggregate (Fig. 11). Crystals of any kind were not observed in the medullary rays, but their cells are filled with starch.

The cambium of 4 or 5 rows is well defined. The average width of the cambium cells radially was 8 microns, tangentially 15 microns, longitudinally 60 microns. The medullary-ray cambium (Fig. 10) consists of nearly cubical cells, though they are sometimes elongated tangentially.

Sections of the bark from a 5-year-old stem were 1.5 mm. in thickness (Fig. 14).

Outer bark—10 to 12 rows of small brown unlignified cork-cells; total radial width 80 microns.

Middle bark—unchanged except for numerous masses of stone cells, usually elongated tangentially, the largest mass being 630 microns, about 20 cells, in this direction. The radial or longitudinal dimension of these stone cell groups seldom exceeds 200 microns, though in one instance a group measured 400 microns. They seldom exceed 8 or 10 cells in these directions. The cell lumen is usually very small, and while pores and stratifications are visible they are not well defined. The walls are strongly lignified.

Inner bark—this is now 1 mm. thick. Occasional groups of unlignified primary bast may still be seen, but many large stone cell-groups have been developed in the outer portion of the inner bark. These groups lie between the medullary rays along with the small groups of first-formed secondary bast. The medullary rays, 1-, 2- or 3-cells wide, are distinctly seen extending back to the cambium. They are from 100 to 300 or 400 microns apart. There were 46 rays in 7 mm. of bark. Between the rays 5 tangential rows of small bundles of secondary bast with crystal fibers were found. In tangential section the bast is in long interweaving strands, 6 to 12 or 14 cells wide, bordering the medullary rays,

the strands separating so as to snugly enclose the ray. The medullary rays are elliptical, ranging in height from 100 microns (8 cells) to 1.5 mm. (100 cells), and in width at their widest part from 30 microns (2 cells) to 90 microns (4 cells). In the majority of cases they are 3 cells wide throughout most of their length, but narrowing to 2 cells, then to 1 cell toward their upper and lower edges.

The phloem contains a few sieve tubes in which the transverse sieve plates could not well be differentiated, accompanied by companion cells and many parenchyma cells. The parenchyma cells are rounded or angular in transverse section, oval in longitudinal section, contain living contents and serve for starch storage. Calcium oxalate crystals, except the prismatic ones in the crystal fibers, are not so abundant in the inner bark as in the middle bark. Occasional rows of rosettes and isolated rosettes and prisms are seen. One isolated prism was noted, measuring 35 microns across, though seldom do crystals of the inner bark exceed 20 microns. The primary crystals of the middle bark, however, attain a diameter of 30 and even 45 microns.

The examination of specimens from the commercial drug gave no new features except a thickening of the inner bark. The thickest piece of bark examined was 8 mm. across. In this specimen the outer bark did not exceed 0.150 mm. and contained 26 rows of suberized cork cells. The middle bark was 1 mm. in width and in 10 sq. mm. contained 34 groups of stone cells, arranged in 4 irregular rows. The inner bark was 7 mm. thick and contained 10 tangential rows of bast bundles. It was noted also that many small groups of stone cells were found associated with the bast in the inner bark (see Fig. 16). Starch was quite plentiful in the medullary ray cells and phloem parenchyma. Rosette aggregates and prisms isolated or in longitudinal rows were fairly abundant and the bast bundles and crystal fibers differed not from previous description.

An unusual specimen was met with, in which the secondary bast was practically absent. The specimen was 5 mm. thick, the middle bark contained stone cell groups and a few such groups were found in the inner bark, but with the exception of a few very small bundles in the outer portion of the inner bark, no bast was found.

It might be said that, on the average, stone cells constitute more than half of the lignified tissue of the drug *Rhamnus Purshiana*.

*The Powder:*—The most conspicuous element of the powder is the masses of bast with the associated crystal fibers. These bast masses in commercial powder (No. 60) are often more than 1 mm. in length and usually 2, 3 or 4 cells wide. The individual bast and crystal fibers are distinguished from one another with difficulty in these masses and only occasionally are the completely separated fibers found in the powder. However, the long rows of prismatic crystals show very distinctly, even after the use of the hydrochloric acid in connection with the phloroglucin test. It is to be noted that when a crystal fiber is observed along an edge of the mass of bast, in profile view as it were, the septum walls which are gradually thickened and lignified toward the thickened lignified wall adjacent to the bast are plainly seen. The outer wall is often missing, being pulled off apparently with the adjacent parenchyma cells (Fig. 22). These bast masses are usually free from any adhering parenchyma.

Almost equally numerous are the masses of strongly lignified stone cells, usually dense and of about 100 to 300 microns in each direction. Some smaller groups and some nearly isolated stone cells are found. The crystals associated with the stone cell groups are not nearly so much in evidence as those on the bast masses. In the larger groups the individual stone cells are difficult to distinguish, but in the smaller (Fig. 17), it is seen that in size, shape and markings they correspond to the description already given.

Fig.14  
RHAMNUS PURSHIANA BARK.

Fig. 14.—Transverse section of bark 1.5 mm. thick from a 5-year-old stem. A—outer bark, B—middle bark, C—inner bark. 1—6 to 12 rows of cork cells; 2—collenchyma; 3—group of mature stone cells with accompanying prismatic crystals; 4—parenchyma with occasional rosettes; 5—medullary ray; 6—secondary bast with crystal fibers; 7—phloem consisting mostly of parenchyma with an occasional rosette or isolated prism of calcium oxalate; 8—cambium. (X 150, reduced  $\frac{1}{2}$ .)

tical, usually 3 cells wide and 8, 10 or more cells long. The cells are irregular or rounded in shape.

Scattered throughout the mount are numerous free prismatic crystals and rosette aggregates. But seldom does the diameter of the rosettes exceed 20 microns or of the prismatic crystals 15 microns.

The parenchyma cells of the medullary rays and phloem are more or less filled with single spherical starch grains seldom exceeding 4 microns in diameter and without distinctive markings (Fig. 19).

(To be continued.)

Fragments of cork, yellowish or brownish in color, are present. They seldom show the very regular arrangement of the cells in radial rows, but present a surface view (Fig. 18), or are irregular masses.

The bulk of the powder consists of masses of parenchyma tissue. The rather thick-walled collenchyma-like cells of the outer middle bark are occasionally seen, pieces of middle-bark parenchyma with rosettes are quite common, and pieces of phloem parenchyma with fragments of medullary rays in either radial or tangential view are abundant. In these phloem masses the cells of the medullary ray in radial view (Fig. 20) average 20 by 25 microns, while their walls are usually thin and unpitted, though sometimes thicker and pitted. In tangential view (Fig. 31), the rays are ellip-

## Section on Pharmacopœias and Formularies

Papers Presented at the Sixty-Second Annual Convention

### THE HOMEOPATHIC PHARMACOPŒIA OF THE UNITED STATES.

GEORGE M. BERINGER, PH. M.

The appearance of the Third Edition of the Homeopathic Pharmacopœia of the United States, is one of the events of the present year that has received very little consideration in pharmaceutical circles. Homeopathic medicines are dispensed by many pharmacists and, in some localities, to quite a large extent. A knowledge of the basic principles of homeopathic pharmacy and the differences in the methods and practices should be acquired by every pharmacist. A more extended acquaintance with the materia medica of homeopathy is essential to those regularly dispensing such medicines and for these a careful study of the book is necessary. It has been the desire of the homeopathic school of medicine to have the Food and Drugs Act of June 30, 1906, amended so as to recognize this volume as the legal authority and standard for homeopathic drugs. These various considerations all indicate that homeopathic standards are of interest and importance to the drug trade and justify the presentation of this paper.

At the meeting of the American Institute of Homeopathy held in Pittsburgh in 1912, a committee of six homeopathic physicians was appointed to prepare a revision of the Homeopathic Pharmacopœia, the previous edition of which had been published about eleven years prior. The following year, the committee reported the completion of the revision and the publication was authorized and the book has now appeared within about two years after the appointment of the committee.

The promptness with which this committee has completed its work, is certainly very commendable. The impression, however, must not be conveyed that the revision has been made with that thoroughness and aim at scientific exactness that has characterized the revision of the Pharmacopœia of the United States.

A critical examination of the volume shows that but very few pages of the previous revision have been rewritten. The third edition contains 680 pages, the second edition had 674; the additional six pages are accounted for by the introduction of a new table "Showing Percentage of Alcoholic Strength of Tinctures."

The revision has been largely one of bookmaking with the rewriting reduced to a minimum. The preface, historical and introductory notices occupy twenty pages as in the previous edition. The General Pharmacy, containing instructions for making tinctures, dilutions and standards for solvents and diluents, occupies the same space and page for page as in the former edition and with only a few minor changes. Part II is devoted to "Special Pharmaceutics," or the official

homeopathic materia medica and, as in the previous edition, this occupies pages 51 to 596, inclusive.

The admissions have been artfully fitted into the text. Where it became necessary to introduce a new drug the plan commonly adopted was to select a drug for deletion and the page plate cut in such a way as to make the changes necessary with the least amount of type setting. Thus on page 482, *Ranunculus Flammula* was deleted and Radium Bromide sandwiched in with two other *Ranunculi* before and two following and thus the strictly alphabetical arrangement was destroyed. On page 532, *Spiræa Ulmaria*, queen of the meadow, was deleted and Sparteine Sulphate was introduced, following *Spigelia* and not in alphabetical sequence. As the text for Sparteine Sulphate occupied less space than that previously required for *Spiræa*, several pages had to be recast, but the printer has minimized the resetting by leaving a blank space for about one-fourth of page 532. These examples serve to show an easy method of pharmacopœial revision.

Ten admissions to the official materia medica are recognized. These additions include a number of medicines more or less used in both schools, such as hawthorn berries, echinacea, white ash bark, thyroid gland, sparteine sulphate, strychnine phosphate and radium bromide. Not the least to be noted as an admission is *Mephitis Mephitis*, Skunk Poison, the offensive fluid secreted by the anal glands of the polecat.

The deletions are *Coriaria ruscifolia*, the toot berry of New Zealand, the strawberry, mercurous acetate, mercury black sulphide replaced by the red mercuric sulphide, *ranunculus flammula*, *spiræa ulmaria*, strychnine alkaloid and linden flowers still extensively used, especially among the Italians.

The volume reasserts that the essentials of homeopathic pharmacy, are the simplicity or singleness of its preparations and cleanliness. The drugs are never mixed or compounded in their preparation or in their dispensing. In accordance with the homeopathic axiom, only one medicine is used at a time. Each drug in its natural state, after proper comminution, is added to a prescribed solvent for the purposes of extracting and preserving and as a means of dilution. Great stress is laid upon the importance of cleanliness and the most conscientious care in the handling of drugs of different kinds so as to protect them from the vapors, odors and dust of others and storage is to be in cool, airy and darkened places.

Drugs are defined "as substances which have the power of disturbing the health of the living organism." The Homeopathic materia medica is in the main derived from the vegetable kingdom; the plant drugs constitute the majority of the official medicines. Thirty-two of the drugs included are of animal origin of which we are informed "only a few are in common use." The mineral kingdom is the source of many and also some of the chemical constituents of plants as well as some artificial chemical products are included.

The dry crude drug remains "the unit of medicinal strength." The directions of the British Homeopathic Pharmacopœia regarding this is adopted. This reads: "In every instance, the dry crude substance is to be taken as the starting point from whence to calculate its strength, and the mother tinctures contain all the soluble matter of one grain of the dry plant in ten minims of the tincture."

In the preparation of tinctures from fresh plant drugs, the amount of moisture present is determined by drying a weighed portion on a water-bath until it ceases to lose weight. Allowance for the percentage of water so determined, is to be made in the preparation of the menstruum. For the extraction of drugs either maceration or percolation is permissible. The former process is "recommended for gummy, mucilaginous substances and those plant drugs having much viscid juice."

It is to be observed that the mother tinctures thus made correspond to the first decimal dilutions (1x). The decimal system of dilution, that is one part of the drug or tincture to nine of diluent, is adopted as the standard and scale of attenuation and notation; so each successive dilution or trituration contains one-tenth as much of the dry substance as the preceding dilution or trituration. The older method of dilution recommended by Hahnemann and adopted for many years by his followers, was the centesimal scale, where each attenuation contained 1/100 part as much of the drug substance as the preceding attenuation. The decimal scale "affords less opportunity for the loss of curative opportunities or 'chances' than the other."

The solvents and diluents employed in homeopathic pharmacy are few and are tersely treated in "Part I, General Pharmacy." The descriptions, properties and tests are not stated with that positive exactness that is observed in other modern pharmacopœias, and the critic will note their insufficiency. Distilled water has no test for limit of ammonia or nitrous oxide. No ash limit is fixed for sugar of milk. Half of an ounce of a hot saturated solution (aqueous)? of milk-sugar is directed to be added to an equal quantity of sodium hydrate to saturation, in order to show the inverting power of alkalis on lactose and subsequent reduction of copper solutions. A few cubic centimeters will be all that a chemist would require to make such tests. Under tests for alcohol it is stated "that when one volume of alcohol is mixed with half its volume of test-solution of potassium hydrate, the liquid should not at once become dark-colored; the non-appearance of the dark color will prove the absence of aldehyde, methyl alcohol or tannin." No other test is given and this certainly could not alone be accepted as a discriminating test for the presence or absence of methyl alcohol.

The directions regarding prescriptions are short and commendable. It is stated that the writing of prescriptions falls exclusively within the duties of the physician; he should exercise the greatest care and exactitude in giving his instructions to the pharmacist who is to be governed by them; not the slightest doubt should exist concerning the physician's directions; the name is to be plainly written, preferably, in Latin; the form should next be stated, that is tincture, dilution, trituration; the dosage form and number of doses should be explicitly given; and the dose and frequency of repetition should be plainly written under the head of "Signa." "Abbreviations facilitate the writing of prescriptions, they do not add to their intelligibility and hence should only be used in strict obedience to rules of abbreviations."

The presentation of the monographs in Part II follows the following general form:— Official title in Latin, Official English title, natural order, if of animal or vegetable origin; Synonyms, Latin, English and Foreign; Description; Habitat; History; Part Used; Preparations.

In those drugs that are considered as very active poisons, "requiring special caution on the part of physician and pharmacist," there is introduced in the paragraph "description," a maximum dose statement. Thus in *Acidum Carbolicum*, "A poison, maximum dose 2 grains highly diluted with water." Under *Acidum Hydrocyanicum*, "An active poison, maximum dose of 2 *per cent.* solution, 10 Minims." Under *Arsenicum Album*, "An active poison, maximum dose 1/12 grain, not to exceed 1/6 grain per day."

As by far the larger percentage of homeopathic materia medica is of vegetable origin, one would reasonably expect to note in this revision a decided improvement in the botany and pharmacognosy. In this we are sorely disappointed as only a few unimportant changes have, here and there, been made. From the studies of botanists and pharmacognocists for many generations, there has accumulated a mass of facts regarding the limitations of botanical families, genera and species; the botanical synonymy; the correction of names and errors of earlier botanists who frequently worked with insufficient materials; the sources of drug and food materials; the structural and anatomical characteristics of plants and drugs, etc. Little, if any, reference seems to have been made by the revisers to this storehouse of available knowledge, and even the work of systematic botanists on our native flora appears to have been neglected, as well as that on the foreign.

The Latin title given to a drug of vegetable origin is commonly the botanical binomial of the plant. As a rule, such titles are quite appropriate, but for others their validity is questionable. As examples, *Guaiacum Officinale* with the synonyms *Lignum guaiaci*, *Lignum vitæ*, *Bois de gayac* and *Guaiaholz* for Guaiac Resin, and *Croton Tiglium* for Croton Oil, which could readily have been placed with the other oils, such as cod liver and castor oils and oils of cajaput and sandal wood.

The determination to adhere closely to the rule to retain as the Latin title the name under which the drug was introduced into homeopathic literature, has led to the continuation of a number of names that should long since have been discarded. Some of these perpetuate old errors and of others it would be quite difficult to trace their history or connection with the drug. The "mephitic and alliaceous" skunk cabbage is a characteristic illustration. The title given is *Pothos Fœtidus*. Presumably this goes back to the *Pothos foetida* of Michaux; but it was early recognized that this plant was very distinct and Nuttall and other botanical contemporaries of a century ago pointed out that this plant could not be classified with the tropical American plants of the genus *Pothos*, nor with *Linnaeus Dracontium*, and so Nuttall classified it under Salisbury's genus *Symplocarpus* and *Symplocarpus fatidus* is the name that was commonly used by botanists for a century. It is now known that Rafinesque had even prior to Nuttall ascribed this plant to a properly described genus *Spathyema*, a name that is very appropriate and has been accepted by Britton and Brown and the more recent systematists as the correct name in accordance with the rules for botanical nomenclature. Yet the correct name, *Spathyema fatida* Raf., is not given even as a synonym.

The subject of Synonyms is admittedly a difficult problem and should be given

consideration in a pharmacopœia primarily for the purpose of determining standards, for defining exactly to what drugs the names are to be properly applied. The treatment here is such as to perpetuate many errors that scientists have long since corrected or buried and to create innumerable questions and doubts as to standards and what it is intended to include under many of the official titles. The revision has done absolutely nothing toward clarifying this confusion and jumble of the former editions.

Under the title of "Synonyms," numerous binomials are given, but in no instance is the authority for the name given. Any one who has paid the least attention to systematic botany, knows how dangerous is such a practice. The same name has not unfrequently been employed by one botanist as well as by different botanists to plants that were later differently classified and properly named. To continue to perpetuate such erroneous and misleading synonyms in a work on drug standards that seeks recognition as a legal authority, is inexplicable.

The few examples of this treatment of botanical synonymy permitted by space, will suffice to exhibit what I consider the grave defect common throughout part II. Under *Aloe Socotrina* are given as synonyms names that are with proper authority considered the sources of East Indian, Barbadoes and Cape Aloes.

*Belladonna* has twelve binomials given as Latin synonyms: two place it in genus *atropa*, two in the genus *belladonna* and eight different *solanums* would include it in that genus.

*Chamomilla* with nine Latin synonyms with six genera named, with *Matricaria Chamomilla* *Linne*, which alone would have definitely fixed a standard, given next to the last.

*Cimicifuga* has nine English synonyms in addition to twelve Latin which classify it with the following genera: *Cimicifuga*, *Actæa*, *Botrophis*, *Christopheriana* and *Macrotys*.

*Cina* (*Santonica*) has eighteen Latin synonyms, twelve of which are binomials and would recognize four species of *absinthium* and eight of *artemisia*. There is certainly need for a more definite statement here as some of the species of *artemisia* named contain no *santonin* and others very little.

*Cinchona Officinalis*, or *China* with *Peruvian Bark* as an English synonym. The Latin synonyms given are mostly those of plants that many years ago were considered as possible sources of commercial varieties of *cinchona*. The change in source due to the extensive cultivation receives scant consideration. *C. succirubra* is named in the text though not included in the synonyms, but *C. Ledgeriana*, *Molus*, is not mentioned at all. It was to the study of the effects of *Cinchona* that *Hahnemann* attributed his discovery of the "law of cure."

*Cistus Canadensis* - Frostweed. Here one notes a veritable confusion. The genus is *Helianthemum* and not *Cistus* as given in the title. The synonyms given include *Lechea major*, which title is properly applied to our common pin weed *Lechea major* *Michx.*, an entirely different plant.

*Digitalis Purpurea* - *Campanula sylvestris* is the first stated synonym. Is it not time that such an error as the naming of a *scrophulariaceous* plant of the genus *Digitalis* as belonging to the *Campanulas* should be forgotten?

*Hyoscyamus Niger*—The synonyms given include *H. agrestis* and *H. flavus*, two of the European species that have been noted as sophistications occasionally collected and admixed with the official *hyoscyamus*.

*Illicium Anisatum*—Star Anise. In this monograph, nine binomials are given, yet the uncertainty of the source is evidenced in the statement under History carried over from the previous revision, "although having many synonyms it is doubtful if star anise is the product of all." The intent is doubtless to describe the innocuous drug star anise, but both in the title (*Illicium Anisatum*) and among the synonyms (*Illicium religiosum*) is the poisonous star anise designated. The revisers were probably not aware of the study made in 1888 by J. D. Hooker, who determined that the true star anise was obtained from a species he named *Illicium verum* and that *I. anisatum* Linnæus and *I. religiosum* Siebold were different names for the plant yielding a false and poisonous substitute for the true drug.

*Scilla Maritima*—Squill. The binomials given would classify this plant as coming from the following genera: *Cepa*, *Ornithogalum*, *Pancratium*, *Sancratium*, *Scilla*, *Squilla*, and *Urginea*.

It is difficult to understand how with such misleading synonymy that purity and singleness of the drugs that it is claimed as so essential to homeopathic pharmacy, can be assured.

The animal drugs include quite a variety, some few of which are common to both schools. Among these may be mentioned Animal Charcoal, Cantharides, Castor (formerly official in the U. S. P., 1870), Cochineal, Musk and Cod Liver Oil. The Honey Bee supplies two titles, that of the *Apis Mellifica* or Honey Bee with directions for making a tincture from the live bees, and the *Apis Virus*, being the Honey Bee Poison, with formula for making a trituration from the extracted stings. The Star Fish, Red Coral, Fresh Water Sponge, the juice of the Purple Mollusk and *Sepia*, the dried inky secretion of the Cuttle Fish, are some of the oddities in this group of drugs.

Among snake poisons are given *Crotalus*, the Rattlesnake venom, the use of which hypodermatically as a cure for epilepsy has been recently exploited in general practice; *Elaps Corallinus*, coral snake; *Lachesis* or Viper; and the *Naja Cobra* venoms.

From the Spiders we have *Aranea* or Diadem Spider, *Mygale* or Bird Spider, the Tarantula, of which two distinct titles and species are named, the Spanish and Cuban, and the *Theridion* or Black Spider of Curacoa.

In the treatment of chemicals, one notes that the tendency has been to follow what has been called the "bob-tail" spelling, that is, using the termination "id" for Chlorides and Bromides, and "fate" for Sulphates. Yet even here there is a lack of consistency. Radium Bromide is found with the "ide" termination, and Spar-teine Sulphate is with the "phate" termination. Yet Cinchonine Sulphate is *Cinchonin Sulfate*. In some of the alkaloids, the U. S. P. rule of terminating alkaloidal names in "ine" has been followed. In others, it has been forgotten. For examples, *Cinchonin Sulfate*, *Eserin*, *Bebeerin*, *Apomorphin Hydrochlorid*, *Pilocarpin Hydrochlorid*. Others are spelled with the "ine," such as Codeine, Hydrastine, Morphine, Narceine, Narcotine, Caffeine, Brucine, Atropine, Atropine

*Sulfate*. In some of the Quinine salts, the Quinine is spelled with "in," the others with "ine" terminations, and for some reason Santonin has been changed to *Santonine*.

Some of the Latin titles given for chemicals and mineral products are simply the English without any attempt at latinizing. For example, Borax and Petroleum.

Throughout the chemical monographs the molecular weights have been corrected on the basis of the recent international atomic weights, but through some oversight there is left in the book (page 606), the old table of atomic weights based on  $H = 1$  and  $O = 15.96$ , and so we have here again a dual standard for atomic weights and calculations of molecular weights.

There is no attempt at assaying any of these chemicals. In the descriptions the strength of standard is sometimes mentioned, but these descriptions are not always of the medicinal article. Acid Hydrocyanic is accompanied with a description describing an acid which boils at  $27^{\circ}$  and congeals at  $15^{\circ}$ . Here the attempt is evidently made to describe the pure Hydrocyanic Acid, yet it is subsequently stated that 2% acid is to be used in making the dilutions and the dose given is for the 2% acid.

Throughout the chemicals the United States Pharmacopœia standard is frequently referred to, sometimes properly and sometimes without recognizing the changes that have taken place in the more recent editions of the U. S. P. Under the title of Ferrum Carbonicum, Saccharated Carbonate of Iron, the process of the U. S. P. VIII is designated. Under the title of Ferrum Iodatum, the synonym of Saccharated Iodide of Iron, a formula is attached credited to the U. S. P. without date. The formula for that preparation, however, is that which was included in U. S. P., 1890. Under the title of Ferrum Muraticum, there is given a formula for the preparation of Solution of Ferric chloride, U. S. P., but here the formula of the U. S. P., 1890, is retained without noticing that the U. S. P. VIII (1900) reduced the Iron content of this solution from 37.8% Ferric Chloride to 29%.

It is to be noted that throughout the book, formulas are only given for the preparation of Tinctures and Triturations with their dilutions and attenuations. No mention is made of other forms of medications that are used in homeopathic pharmacy, such as liniments and ointments and for which standard formulas should be included in a pharmacopœia.

Part 3 of the book is devoted to select tables for reference. The first of these is the list of signs and abbreviations used in prescription writing. Another useful table is that of the list of medicines with the pronunciation of the titles correctly indicated.

#### SENSITIVE TEST FOR IRON.

A little hydrazine is added in order to reduce ferric to ferrous iron, or to prevent oxidation of ferrous salt. To 50-70 mls of the solution a little saturated alcoholic dioxime solution is added. If the smallest traces of iron are present the liquid becomes intensely red. L. Tschugaeff and B. Orekin (*Zscht. Anorg. Chem.*, 1914).

## Editorial

ERNEST C. MARSHALL, Acting Editor.....63 Clinton Building, Columbus, Ohio

### THE FUTURE.

THE question of what is to be the pharmacy and the pharmacist of the future is one most interesting, naturally, to all the members of our profession. The changes which have come within its practice within a few short years, have caused us to deeply consider the question, What is to be the outcome to Pharmacy of all this apparent radical, this ultra change in ambition and in development?

Of course it is folly to regret this change. Mutation is inevitable in all things. Everywhere there is a constant evolution or devolution in progress, from which metamorphosis must result and which we must inevitably encounter and for which we must be prepared.

It has seemed always to be the desire of man to produce something immutable. The Pharaohs, when they built their pyramids and placed within them their sarcophagi, wished to build for all time and vainly thought they could there rest until the last day. The priests of all the ancient religions, of the Temples of Vesta and Mars, of Jupiter and Saturn, the very altars of which stand unworshipped in the Forum of to-day, all thought the faith they revered was to endure till the end of time. In all things we must anticipate a change, and hold ourselves in readiness to guide that change rightly and for the good of all.

We fear to break from the established course; we do not like to be forced from our accustomed surroundings; we know the evils we have, but know not those which may come to us under new conditions, when we cut adrift and sail out over the unknown and uncharted seas.

From the days of Accad, of which we get our first mention in Genesis, the science of Pharmacy has been in constant process of evolution, and through the chiliads of years, since that time, there has been a constant, never-failing change, progression and regression, like the ever-moving waves upon the ocean's bosom; the tides upon the shingly beach.

So knowing the absolute certainty with which changes are to come, it is for us to seek,—not to retain the old conditions, the old ways and the old methods,—but to boldly and resolutely strive to make these changes such as will elevate and uplift the science and the art of which we are the disciples.

To the ordinary mind it would almost seem that Pharmacy, as we knew it, that of the olden time, had so radically changed that but slight connection existed between that and the art of Pharmacy of to-day. But these changes are but of the surface. Pharmacy is to-day as it has always been since the days of Babylon and Nineveh and the cuneiform prescriptions, the science and the art of preparing medicines for the healing of the sick. And so it will continue to be until the end of time. The "Telinon" and the "Mendesium" of the ancient Egyptians were

prepared in the same way as our ointments are prepared at the present time. And when Macaulay's traveller from New Zealand "shall in the midst of a vast solitude, take his stand on a broken arch of London Bridge to sketch the ruins of St. Paul" then will Pharmacy be still existent, ministering to the ills and woes of Humanity.

With such a prospect before us we should simply look upon the aberrations of the pharmaceutical horologe as only most ephemeral. We are passing through what we might term the "Dark Ages" of Pharmacy: a pharmaceutical regression, from which Pharmacy will emerge purified and better. It is impossible for Pharmacy to permanently move backward. It is a science and as such it can never die. The soul, the essence of Pharmacy, is its knowledge of drugs which makes it useful to mankind. Surround it as you may with Commercialism; adulterate its pure stream as you will with baser things, yet above all, there must come a time, when these things will pass away and the pure bright light, radiating from its torch, will shine forth in undimmed radiance. This time must come, for

"Knowledge is now no more a fountain sealed;  
Drink deep until the habits of a slave,  
The sins of emptiness, gossip and spite,  
And slander die. Better not be at all  
Than not be noble."

And it is to make Pharmacy noble and great that we should dedicate ourselves.

How can we do this? By making ourselves noble and great. By adding to ourselves each day something of knowledge which will all tend to the uplift of our profession, to the making of that profession noble.

The Pharmacy of America is determined by the character of its fifty thousand pharmacists, and upon us depend the question whether it shall be noble or ignoble, base or true.

In this work the American Pharmaceutical Association must take a leading part. It should keep its face steadily toward the rising sun of progress and, putting aside all base and lowering tendencies it should uphold the dignity, the purity of Pharmacy and its aims.

"Once to every man or nation, comes the moment to decide,  
In the strife of truth with falsehood  
For the good or evil side."

And it is for us, at this moment to decide that Pharmacy shall be noble, shall be pure, shall be true to itself and to its traditions.

Let every one of us gird himself to this work. Let us highly resolve, each day that we as pharmacists will be better, more noble and more skilled, and we will do our part to make of Pharmacy what we all desire to see it,—not merely an end to the attainment of worldly wealth, but a means of serving humanity better, more wisely and well.

## THE UNSOLVED PROBLEMS OF CHEMISTRY.

A NUMBER of years ago Prof. Ira Remsen of the Johns Hopkins University wrote a most entertaining paper on the above subject and to-day the questions to which it called attention are as involved as they were at that time. There still remain these unsolved problems which some day we may hope to master, but which, at the present time, are as difficult and impossible for us to solve as is the *pons asinorum* to the primary student of arithmetic.

Who can tell us definitely what becomes of the sugar we dissolve in our daily cup of coffee or tea? We say it is in solution, but what is the meaning of that term? We can recover it from that solution to be sure, but in what form is it while it is in that solution. People said the apple "fell," but until Newton no one knew the universal law, which acts on the mightiest of suns and the tiniest of sands; which holds Boötes and Sirius and the Great Bear in their fixed places in the everlasting heavens.

We speak of elements, what are they? Things impossible to simplify? No, things it is impossible for us to break up, that is all. What we know is but little more than Boyle knew when he wrote his *Scyptical Chymist* in 1660 and then the four elements, earth, air, fire and water, were the last words of science on the elementary things of the world.

If the Cosmos is the result of evolution, as scientists tell us, then all the elements must have had a common origin. If all life comes through the protoplasm and the protozoa, then a common source must exist for all living organisms. But of all this we have not the faintest knowledge. The diamond and the graphite of the lead-pencil are the same element we are told. Both pure carbon. If so why do they differ? Why should the one be hard and the other soft, one translucent and one opaque, one conduct electricity slowly and the other with facility?

We think we know all about water. We know its constituents, hydrogen and oxygen, but why does it dissolve as much chloride of sodium at 32° as at 212° when it dissolves much more of other substances at the higher temperature? Why does it suddenly expand when it freezes?

To many of these and like other problems the pharmacist has an introduction and it is to the credit of the profession that some of the greatest advances in chemistry came through the humble pharmacist's apprentice. Scheele entered the drug-business at the age of thirteen and Baron Liebig began his apprenticeship in a drug-store at fifteen. And so to these unsolved problems of chemistry we invite the attention of all pharmacists. Study and thought are the essentials of all advance. Not alone the study of books, but the study of things and these things are immediately under the eye of the pharmacist. To every boy entering the drug-business to-day the opportunity is offered to solve some of these problems and mark a step in the world's advance.

## Book Reviews

DIGEST OF COMMENTS ON THE PHARMACOPOEIA OF THE UNITED STATES OF AMERICA (VIII) AND ON THE NATIONAL FORMULARY (III) for the calendar year ending Dec. 31, 1913 by Murray Galt Motter and Martin I. Wilbert, Bulletin 98, Hygienic Laboratory.

It is with pleasure that we can say in all sincerity that this Manual should be in the hands of every pharmacist who is truly a pharmacist, in this country.

There is not a page in the book but what is of interest to all those actively interested in the drug-business in any department. While there is much in the book that is alien to its title, yet no fault can be found with a line of its contents which are well-selected and well-arranged to impart useful knowledge to druggists regarding many points upon which they may need information.

It is more than its title would signify. It is really a Review of the field of Pharmaceutical literature for the year, which in any way has a bearing on the intent or the contents of the U. S. P. and N. F. Instead of being devoted to the past alone it is of the present that it presents a picture and it contains in its pages a wealth of information which, if utilized, cannot fail to elevate and improve the practice of pharmacy and to furnish valuable information to every pharmacist.

Any one who examines the publication will be surprised at the amount of information it contains upon all subjects connected with the practice of Pharmacy and we urge our readers to secure this book in order that they may be advantaged by the information contained within it.

It would be most regrettable for any druggist not to take advantage of this knowledge, so freely offered. Subjects are treated briefly but the references it contains allow any one to easily consult the source of the knowledge upon which he may desire further information.

The book might very well be termed an Annual of Pharmacy of the United States and merit well the more comprehensive and desirable cognomen.

---

### TESTS FOR VANILLIN.

Vanillin gives with certain classes of organic substances typical color reactions under the influence of hydrochloric or sulphuric acid. The observations made with amines, acid amides, and imines (where the color becomes yellow), and with phenols (where the color becomes red and violet) give hope that with other classes characteristic colors may also be produced. Many of the tests referred to may also be used in cases in which a positive result with phenylendiamin, phloroglucin, or resorcin is reckoned to be insufficient. E. P. Haussler (*Zschft. Anal. Chem.*, 1914).

## Contributed and Selected

### REPORT OF THE CHEMISTS' SUB-COMMITTEE ON STANDARDIZATION AND DRUG TESTING.

The General Committee on Standardization and Drug Testing have requested that we investigate methods of analysis for Elixir Lactated Pepsin, nitroglycerine, diastase and papain preparations.

Each of these problems has received our most careful attention. All of the methods herewith recommended have been tested in our laboratories. We present them to you as being the most efficient known to us at this time.

#### ASSAY OF ELIXIR OF LACTATED PEPSIN.

Since the different pharmaceutical houses market this preparation in various strengths, it is impossible for us to describe other than a general method. We suggest that you take of the elixir, a quantity containing approximately 0.1 gram of pepsin. Dilute this to 150 cc. with a solution of 9 cc. dilute hydrochloric acid (U. S. P.) in 291 cc. distilled water. Proceed from this point directly as outlined in the Pharmacopœia of the United States, Eighth Revision, under the Assay of Pepsin, page 335. It will be found that the other ingredients present in the original elixir will not interfere with the pepsin digestion in the dilution above recommended.

We believe the pepsin assay to be the best method of testing the activity of this elixir. However, we also strongly recommend that you estimate the alcohol contents of each and every lot, since it is advisable to verify the statements of alcohol percentage made on the label.

As you well know the methods of alcohol determination in general practice today, are still more or less inaccurate. We believe that the forthcoming Pharmacopœia is to give us an official method. This will be welcomed by all. Meanwhile we suggest that you employ the distillation-method described in Leach's "Food Inspection and Analysis," 1911 edition, page 658.

#### ESTIMATION OF NITROGLYCERIN.

Two determinations are necessary, one on the original supplies and the other on the finished products. There are available, two types of raw material, one an alcoholic solution and the other a trituration of nitroglycerin with some inert material such as milk sugar. Likewise the finished products are of two types, the alcoholic solution and the tablets.

Engelhardt (Journal of the American Pharmaceutical Association, 1913, page 163,) states that rather accurate results are obtained in the assay of alcoholic solutions of nitroglycerin by evaporating a measured sample spontaneously and drying the residue in a desiccator over sulphuric acid to a constant weight. We are told that this method has been approved as the official assay of the new Pharmacopœia. You will find full details on page 527, Journal of the American

Pharmaceutical Association, year 1914. You may, however, also proceed as described later under the estimation of tablets and triturations by diluting the alcoholic solution to a definite volume with ether in a manner as suggested under the "Preparation of Sample."

As you know, the Department of Agriculture has recommended two colorimetric-methods for the assay of nitroglycerin, the Modified Scoville and Modified Hay methods. For the estimation of both the original trituration used for manufacturing, and the finished tablets we can only repeat their method. We take exception, however, to their method of extraction by macerating the tablets or trituration under ether and using this ether-extract for the determination. There is no doubt but that this method will exhaust a good hypodermic tablet. However, it has been clearly proven by Dr. Thorburn of the Pitman-Moore Company and verified by Mr. Summers in the Laboratories of The Abbott Alkaloidal Company, that this method does not completely exhaust compressed tablets, granules or poorly made hypodermic tablets. It therefore seems advisable to us to recommend Dr. Thorburn's extraction-method in preference to the maceration-method.

#### ESTIMATION OF NITROGLYCERIN IN TABLETS OR TRITURATION.

*Preparation of Sample (Thorburn Modification):*—Disintegrate a quantity of tablets or trituration containing about 0.0162 gram ( $\frac{1}{4}$  gr.) of nitroglycerin in 20 to 25 cc. of water. Extract four times with successive portions of 25 cc. of ether. Combine ether extracts and make up to 100 cc. in a volumetric flask. Then proceed by either of the following methods.

*Estimation by the Modified Scoville Method:*—Of the above ether solution place 40 cc. in a carefully dried and tared 50 cc. beaker. (A second aliquot of 20 cc. may be used as a check.) Evaporate the solvent in a vacuum desiccator. Apply the vacuum gradually so as to prevent ebullition. Leave the beaker in the vacuum 30 minutes after the ether has evaporated. Weigh and calculate ether extract per tablet. Treat the residue with 2 cc. phenoldisulphonic reagent, rotating the beaker in such a way that the reagent comes into contact with the entire inner surface. After 10 minutes add water and wash into a 100 cc. flask. (If a check analysis as suggested was made, wash this into a 50 cc. flask.) Dilute to the mark and place 10 cc. (representing 1 tablet) in a 100 cc. flask, add about 50 cc. water and a few drops more potassium hydroxide solution (20%) than is required to neutralize the acid. (Do not use sodium hydroxid.) Dilute to the mark and compare the color with that produced by a standard nitrate solution similarly treated. Use any convenient colorimeter or Nessler tubes.

#### Reagents and Standards:

*Phenoldisulphonic Acid Reagent:* Dissolve 25 grams of pure white phenol in 150 cc. of concentrated sulphuric acid, add 75 cc. of fuming sulphuric acid (13%  $\text{SO}_3$ ), stir well and heat for two hours at about 100 degrees.

*Standard Solution:* Dissolve .7217 gram pure  $\text{KNO}_3$  in 1 liter of water. Evaporate 10 cc. of this solution just to dryness on the steam bath. Cool and treat the residue with 2 cc. phenoldisulphonic acid reagent, observing the precautions noted above and using a glass rod if necessary to aid the solution of the

residue. After 5 or 10 minutes dilute to 250 cc. Each cc. of this solution contains .004 mg. nitrogen. Add an excess of KOH solution to an aliquot of this solution and dilute to 100 cc. It is advisable to prepare a standard of approximately the same color as the unknown. Nitroglycerin is 5.4 times nitrate nitrogen.

*Estimation by the Modified Hay Method:*—Of the above described ether extract place 10 cc. in 120 cc. Erlenmeyer flask, dilute with 5 or 10 cc. alcohol and add about 5 cc. of  $\frac{1}{2}\%$  alcoholic potassium hydroxid. Cover with a watch glass and allow to stand 10 minutes. Place on steam bath, allow to boil, remove the watch glass, and when most of the liquid is evaporated, add about 25 cc. water and leave on steam bath until the odor of alcohol can no longer be detected. Cool and dilute to 250 cc. Each cubic centimeter of this solution represents .01 of a tablet. Introduce 5 cc. representing .0324 milligram nitroglycerin into a 100 cc. graduated flask, dilute with sufficient water to make the volume 90 to 95 cc., add one drop concentrated hydrochloric acid, then 2 cc. sulphanilic acid solution and 2 cc. naphthylamine hydrochloride solution. Complete the volume with water. Prepare at the same time and in the same way, standards containing known amounts of sodium nitrite, by taking 80 cc. of the standard solution of sodium nitrite, and adding one drop of concentrated hydrochloric acid, 2 cc. sulphanilic acid solution and 2 cc. naphthylamine hydrochloride solution, and completing volume to 100 cc. with water. Stopper the flask and mix well. Compare the colors after 30 minutes, each cc. is equivalent to .00064 mg. nitroglycerin.

Reagents and Standards:—

*Sulphanilic Acid Solution:*—Dissolve 1 gram in 100 cc. of hot water.

*Naphthylamine Hydrochloride Solution:*—Under a hood boil .5 gram of the salt with 100 cc. of water for 10 minutes, keeping the volume constant. Filter and keep in a glass-stoppered bottle.

*Standard Solution of Sodium Nitrite:*—To a cold solution of about 2 grams of sodium or potassium nitrite in 50 cc. of water, add a solution of silver nitrate as long as a precipitate appears. Decant the liquid and thoroughly wash the precipitate with cold water. Dissolve in boiling water. On cooling the silver nitrite is precipitated. Dry the crystals in the dark at the ordinary temperature (preferably in a vacuum). Weigh out 220 milligrams of the dry silver nitrite, dissolve in hot water and decompose with a slight excess of sodium chloride. When the solution becomes clear, dilute to 1 liter. Dilute 5 cc. of this solution to 1 liter. This second dilution is the standard to be used. It contains 0.0001 mg. nitrite per cc.

Only nitrite free water should be used in the estimation by the Modified Hay method.

Of the above methods the Scoville is more generally employed because of the rapidity with which it can be operated. It is to be remembered, however, that both of the above methods involved a colorimetric comparison, and that different operators are better able to judge one color in preference to another. As you well know, the Scoville method gives a yellow-colored solution while the Hay method yields a rose-colored solution. We suggest, therefore, that you try both methods on a known standard and then adopt the one that gives the most consistent results. So far as accuracy is concerned, outside of the end color comparison neither method is to be preferred over the other.

This committee most emphatically reiterates Mr. Baker's statements to you of a year ago that nitroglycerin tablets when properly bottled do not deteriorate on standing. During the past year, we have tested monthly a specimen lot of tablets. These tablets are to-day as potent as they were one year ago.

All that is necessary is to devise a method of manufacture which will give a product true to label, then bottle properly.

#### DIASTASE.

As you all probably know, diastase is to be official in the forthcoming Pharmacopœia. We are also to have an official method of assay. The provisional method has already been described on page 15 of Part 1, First Proof, United States Pharmacopœia, Ninth Revision.

As Mr. Baker of the Norwich Pharmacal Company, has closely studied this method for the committee, we deem it best to quote his complete report on this subject.

"Comparison and Criticism of Two Methods for Determining the Starch Converting Power of Diastase."

"I will represent the method proposed for the pharmacopœia, ninth revision, as method (a) and the method used by the N. P. Co. as method (b). This method is taken from, but slightly modified, to the one adopted by the Council of Pharmacy, A. M. A., as printed in the Journal A. M. A., Vol. 51, No. 2, Page 142.

"Method (a) is as follows: Mix a quantity of potato starch which has been purified as described under *Pancreatinum*, equivalent to 5 gm. of dry starch, in a beaker with 10 cc. of cold distilled water. Add 140 cc. of boiling distilled water, and heat the mixture on a water-bath, with constant stirring for 2 minutes, or until a translucent uniform paste is obtained. Cool the paste to 40° C. in a water bath previously adjusted to this temperature and add a solution of 0.1 gram of Diastase in 10 cc. of distilled water at 40° C. just previously made. Mix well and maintain the same temperature for exactly 30 minutes, stirring frequently, when a thin, nearly clear, liquid should be produced. At once add 0.1 cc. of this liquid to a previously made mixture of 0.2 cc. of tenth-normal iodine V. S. and 60 cc. of distilled water. No blue nor reddish color should be produced.

"Method (b). A clean grade of potato starch is thoroughly washed and carefully dried at a low temperature and finally at a higher temperature to about a 10% moisture content. The exact moisture content to be determined in a separate experiment. For the test enough of the starch is taken (about 11 gms.) to make to 500 cc. of an exactly 2% (anhydrous) starch content. The boiling of the paste should be continued for 10 minutes with constant stirring to keep from burning. For each test quantities of exactly 25 gms. of the paste are weighed in a series of 250 cc. flasks placed in a water-bath and kept at a temperature of 40° C. The iodine test solution is made by dissolving 2 gms. of Iodine and 4 gms. of Potassium Iodide in 250 cc. of distilled water, 2 cc. of this solution is then diluted with pure water to make 1000 cc. The diastase solution is made by dissolving or suspending 0.2 gms. of diastase in 100 cc. of distilled water. The solutions are used in the following way: Definite volumes of the solution are added to the different flasks containing the starch solution and the mixtures are well shaken. The volumes added may be as follows: 4 cc., 4.5 cc., 5 cc., 5.5 cc., 6 cc. In eight minutes tests are begun by removing volumes of 5 drops from each of the digesting mixtures by a pipette and adding this to 5 cc. of the dilute iodine solution in a clear white tube standing over white paper. If at the end of 10 minutes drops from one of the flasks fail to give the iodine reaction, we are ready for the more accurate test; for example, the flasks containing 5 cc. diastase solution did not respond to the iodine reaction, but the one containing 4.5 cc. did, then a second test would be carried out under exactly the same conditions as the former using 4.6, 4.7, 4.8, 4.9 and 5 cc. diastase solution to 25 gms. of the starch paste. The diastase solution must be of the same temperature as the starch paste. The test is carried to the loss of all color. The diastase solution should have been just previously made and, if working for any length of time, fresh solutions should be made from time to time, as aqueous solutions of diastase are very unstable and soon lose their power of conversion. The dilute iodine solution should not be put in the tubes until just before it is needed.

"A good diastase will convert at least 50 parts of starch to a colorless end point in 10 minutes. While this method is a 10 minute and the other method a 30 minute one, both methods checked on the diastase under examination as the following figures will show.

Method (a)		
Diastase parts.	100% starch to colorless end point parts.	Time.
" 1	" 40	10 minutes
" 1	" 50	15 "
" 1	" 55	22 "
" 1	" 60	30 "
Method (b)		
Diastase parts.	100% starch to colorless end point parts.	Time.
" 1	" 40	6 minutes
" 1	" 50	8 "
" 1	" 60	10 "
" 1	" 70	13 "

"The fact that the 10 minute method gave the same results as the 30 minute method is due to the vast difference in the strength of the Iodine solutions used. In method (a) we have 0.00254 gms. of Iodine in 60 cc. of water, while in method (b) we have but 0.00008 gms. in 5 cc. We, therefore, have 32 times more Iodine present in method (a) than in (b) and this will give a reaction with the starch diastase solution when the weaker one will not. This condition exactly counteracts for the difference in time for the two methods.

"Method (b) has a few important advantages over the one proposed for the U. S. P. 9th revision. The first and most important point is that when the starch paste is once made, twenty tests may be made from the 500 gms. With method (a) we are using a cumbersome amount of starch paste for each individual test and the test simply shows whether or not the sample tests are up to the U. S. P. standard and to find the exact value of the diastase will require probably several tests, which will make a very tedious task, making and cooling such large individual quantities of starch paste and the individual weighings of the diastase and also the longer period of time for each test.

"The second important point is the end point for the two methods used. In method (b) the end point is very delicate and cannot be mistaken as 5 cc. of the dilute iodine solution in a Nessler tube appears nearly colorless, and any blue, red, or yellowish color which may be produced can be detected with sufficient accuracy. In method (a) the solution is quite highly colored with free Iodine. The directions state to add 0.1 cc. of the starch diastase solution to the 60 cc. of the Iodine solution and no blue or reddish color should be produced. While there are no instructions calling for this, a careless or thoughtless worker might shake the tube slightly and disseminate a red color that is actually produced, so that it would be impossible to be detected. This allows a chance for a sample to be reported up to standard when possibly the starch is only taken to the dextrose or maltose stage.

"Both methods call for potato starch. While potato starch will give a higher value for diastase, and this may seem as a case of lowering standards instead of raising them, I am in favor of its use, because of the physical characteristics of the two. I have always been able to prepare a much more uniform paste from potato starch than from corn starch and would prefer raising the standard to 1/60 or 1/70 and still use potato starch."

The above discussion comparing Mr. Baker's modified method to the proposed pharmacopœia method is entitled to your profound consideration. As has been pointed out, Mr. Baker's method enables you to easily determine the exact strength of your diastase, while the proposed method for the Pharmacopœia is little more than a qualitative method. We believe that this Association should adopt Mr. Baker's assay for their official method. We also deem it advisable for the Association to send a copy of Mr. Baker's report to Prof. Remington, Chairman of Revision Committee, for his further consideration as a better method for the new Pharmacopœia, for it is well to remember that no matter how poor a method may be, should it be included as the official method in the forthcoming Pharmacopœia, the Association members will be compelled to adopt it in their laboratories. The time has come when the Pharmacopœia has become a legal standard rather than a pharmaceutical guide.

#### PAPAIN.

The final subject for consideration assigned to us by the General Committee is the assay of papain. This is indeed a difficult task.

There is considerable difference of opinion among the various authorities not

only upon the media to be employed but also the substance to be digested. It appears that papain contains two distinct enzymes—one acting in acid and the other in alkaline media. Arguments have also been advanced in favor of testing papain not only on raw beef but also on blood fibrin or egg albumin. It is our opinion that raw beef is the best substance for this purpose, since it more nearly duplicates in the laboratory the function of papain in the body.

Graber (*Journal Industrial and Engineering Chemistry*, 1911, Page 921), has shown that papain is most active in acid-solution, neutral media ranking second and alkaline media, third. While this may be true, the testing of papain in acid solution does not eliminate an adulteration with pepsin. It has been found in the Laboratories of The Abbott Alkaloidal Company, that a 5% adulteration with 1/10,000 pepsin would give an otherwise inert papain an activity of 1/30, when tested in acid media. The true question is "how does the papain react in the body?" If it digests fibrin best in acid solution, it will perform this function in the stomach and not in the intestine as is now maintained by some. We should, therefore, devise some method that will eliminate adulteration with pepsin and still show the active power of the papain in acid solution.

A method now in vogue for testing papain in acid media is that of Graber, described in the *Journal of Industrial and Engineering Chemistry*, 1911, Page 921.

As a method for assaying papain in alkaline media we recommend the following, devised by Mr. Baker. It is conducted as follows: "The test is 1:30 in 6 hours at 50° C. That is, one part of papain should in 6 hours at 50° C. so completely digest and disintegrate 30 parts of raw beef that the undigested residue should not measure more than 2 cc. using 10 grams of beef for each experiment. The test is conducted on round steak free as possible from fat and gristle, which has been finely minced by passing through a meat chopper. For each test 10 gms. of beef, 100 cc. of distilled water made slightly alkaline to litmus with sodium carbonate, .3 gm. of ferment. Invert bottles once every 10 minutes as per U. S. P. test for pepsin. Pour in tall graduated cylinder at the completion of the assay."

While we have called to your attention these two methods, yet we most strongly recommend the following promising method proposed by Mr. Thorburn. This method is both unique and ideal in that it not only tests the papain in both alkaline and acid media, thus giving the total digestive activity, but also eliminates the possibility of adulteration with pepsin; as the pepsin, if present, is destroyed in the preliminary digestion. This method appears to us to be the best yet proposed for the assay of papain. The method is herewith quoted from Mr. Thorburn's report to the committee.

"Dissolve papain .400 gm. and sodium bicarbonate .750 gm. in distilled water enough for 100 cc. Heat to 50° to 55° C.

Scrape lean round steak (better results are obtained by scraping the meat to a pulp instead of grinding) rejecting gristle, fat, etc., to a pulp; weigh 10 gm. meat pulp and place in a 200 cc. digestion-flask; add 100 cc. of the warm solution of papain and sodium bicarbonate. Digest for four hours, shaking the mixture once every 10 minutes; then pour into a measuring cylinder and let stand at rest for one-half hour. If the digestion flask is fitted with a stopper carrying a small graduated tube it is of course much more convenient than pouring into a cylinder; in this case invert the flask and read after one-half hour's standing.

A blank digestion of the meat pulp with sodium bicarbonate should be carried along with the papain digestion.

Not more than 10 cc. of residue should remain after the alkaline digestion with papain.

After reading this residue, warm the mixture to 50° to 55° C. and add concentrated hydrochloric acid 1½ cc.—sufficient to neutralize the alkali and leave .2% to .3% of free acid.

Again digest for four hours shaking every 10 minutes. Let stand at rest one-half hour, then read the residue which should be less than three cc.; this gives the total digestive power of the papain as 1 to 25 four-hour tests which compares favorably with a 1 to 30 six-hour test."

It occurs to us that you would welcome our calling to your attention those drugs and chemicals that each of us have found deficient during the past year. We do this to impress upon you the importance of testing all your supplies, and also the fact that the label or brand is no criterion to purity. Each and every member of this association should at least test all crude supplies. We recommend this not only for your individual welfare but also for the good of the profession. You should also check-test your finished products. You should all attain that position where you can state that your goods absolutely conform to the label, in that they contain the exact quantity of the best obtainable drug as thereon stated. To do this you must invoke the services of the pharmaceutical chemist.

Mr. Baker reports the following as a list of crude drugs and chemicals rejected at the chemical laboratory of the Norwich Pharmacal Company during the past year.

Alum, dried	Continued marked quantities of material insoluble in water.
Ammonium Carbonate	Badly decomposed.
Benzoin	Three different lots rejected, all deficient in alcohol-soluble contents.
Balsam of Tolu	Deficient in alcohol-soluble content.
Balsam of Tolu	Contained rosin.
Black Haw	Not true Black Haw but so-called Variety Black Haw.
Short Buchu	A large percentage of stems present.
Chloroform in bottles of 100 gms.	Shortage in weight of contents, varying from 68.7 gms. to 94 gms.
Cinchonine Sulphate	Melting point low and chloroform-soluble deficient.
Calcium Hypophosphites	Solution in water decidedly opaque.
Coca Leaves	The leaves had deteriorated badly, odor musty, ether-soluble alkaloids but .09%.
Calcium Glycerophosphates	Contained appreciable amount of chlorides.
Calcium Glycerophosphates	Contained an appreciable quantity of citric acid.
Calcium Carbonate	Two lots, aluminum in excess the U. S. P. limits.
Cannabis American	Resin content low 6.5%.
Cayenne Pepper	High in ash content, total ash 9.86%. HCl insoluble ash 5.6%
Chlorophyll	Odor very disagreeable.
Cresol	Gravity low, insoluble in water as it contained tarry matter.
Hops	Rejected, as they were inferior in both color and odor.
Henbane	Assayed .15% mydriatic alkaloids which was suspiciously high
Iron Peptonate	Assayed 20% Fe <sup>2</sup> O <sub>3</sub> , label claimed 25%.
Iron Peptonate	Rejected on odor.
Iron Sulphate, dried	Gave moisture content of 33%.
Gelatine	Three lots rejected on account of color.
Gentian Powd.	Adulterated with foreign material.
Glycerine	Contained sulphates and color not up to standard.
Glycerine	Color not up to standard.
Guaiaic	Four lots, rejected, low in alcohol-soluble content, high in ash content.
Lard	Two lots rejected on odor.
Lithium Citrate	Did not conform to the U. S. P. in purity test.
Lupulin	Five lots rejected—ether soluble content deficient—ash content high.
Licorice Root	The extract obtained had a musty taste.

Lobelia	Rejected as it was mostly stalk and but very few leaves.
Manaca Root	Spurious variety.
Mentha Piperita	Inferior in both color and odor.
Po. Gum Myrrh	Ash content high 15%.
Magnesium Sulphate	Contained the heavy metals in excess of the U. S. P. limits.
Magnesium Sulphate	Purity not up to U. S. P. standard—color also inferior.
Magnesium Oxide heavy	Contained excess of calcium.
Nux Vomica	Physical appearance of the seeds was poor—strychnine content 1.222%.
Oleic Acid	Congeaing point 14° C., which is high. Notable quantities of palmitic and stearic acids present.
Oil Thyme	Color very dark.
Russian White Oil (Liquid Petrolatum)	Two lots rejected on account of turbidity.
Phenol	The crystals were off color, being quite red.
Peptone from Beef	Proteid content 71%, which is below our standard.
Pareira Brava	Spurious variety.
Paraffin	Tastes strongly of mineral oils.
Podophyllin	Two lots rejected, deficient in alcohol-soluble content and high in ash content.
Potassium Hypophosphite	Solubility in water not in accordance with the U. S. P.
Peroxide of Hydrogen	Assayed 2.8% $H_2O_2$ —contained free acid and total solids in excess of the U. S. P. limits.
Pink Root	Contained a large amount of earth and dirt.
Gum Senegal	Contained too large an amount of wood.
Squaw Vine	Inferior in physical appearance.
Strophanthus Seeds	Very damp and musty.
Strontium Salicylate	Two lots rejected as color was decidedly pink.
Zinc Oxide	Two lots below U. S. P. standards for purity.
Zinc Valerianate	Two lots below U. S. P. standards for purity.
Vinegar	Gravity and acidity below N. Y. State requirements.

Mr. Thorburn has enclosed the following memorandum to illustrate the need of analytical work as a control in drug compounding. He states that "We have tabulated the last one hundred samples submitted to the scientific department by the manufacturing departments. These samples represent forty-six different preparations and involve about twenty different kinds of determinations such as the estimation of arsenous acid, ammonia, alkaline hydroxides, pepsin, iodine, iodides, lead, ethyl nitrite, phosphoric acid, hydriodic acid, jalap resin, alkaloids from aconite, gelsemium, ipecac, nux vomica, opium, pilocarpus, belladonna, henbane, stramonium, and extractive from various drugs.

"Of these one hundred samples fifty-one were below standard strength, thirty-two complied with the official standard and seventeen were above standard.

"Some extreme cases of deficient strength are worth noting; 2 samples of Fld. Ext. Berberis were 60% and 67% below; 2 Stramonium preparations were 50% below; Fld. Ext. Hyoseyamus varied from 13% to 39% below; Solution Iodine Compound was 47% below; 1 sample of syrup Hydriodic Acid was 50% below; Fld. Ext. Nux Vomica varied from 1% to 19% below and from 2% to 20% above; Fld. Ext. Gelsemium was 48% and 55% below.

"Few of the samples that were above strength were more than 10% above but Extract Belladonna Leaves finished 55% above standard. A number of Pepsin digestion tests gave very satisfactory results but in several cases these samples were more than 25% below standard.

"This series of samples is good evidence that no scheme or plan for the manufacture of pharmaceutical preparations is complete unless it includes the analytical testing of the article after it is compounded and most important of all, its adjustment to standard."

The Abbott Alkaloidal Company report having rejected the following supplies:

Aconite	Low in alkaloidal content.
Alcohol	Excess organic impurities.
Alum	Excess iron.
Apomorphine Hydrochloride	Excess moisture.
Arsenous Acid	Insoluble matter.
Barium Sulphide	Two shipments purity but 19 to 22%.
Calcium Chloride	30.9% water.
Calcium Carbonate	Chlorides.
Chloral Hydrate	Low melting point. Chlorides.
Corn Oil	Less than content.
Diacetyl Morphine Hydrochloride	Excess water.
Hydrastinine Hydrochloride	Excess water.
Ipecac	Low alkaloidal content.
Lanum Hydrous	Moisture.
Methylene Blue	Ash.
Milk Sugar	Insoluble matter.
Morphine Hydrobromide	Excess water.
Nux Vomica	Low alkaloidal contents.
Oil of Cajuput	Copper.
Oil of Peppermint	Dimethyl Sulphide
Papain	Digestive activity.
Potassium Permanganate	Chlorides. Sulphates.
Sodium Bisulphite	Moisture.
Sodium Silicofluoride	Purity.
Strophanthin	Reduced alkaline cupric tartrate in cold.
Talc	Iron.
Tartaric Acid	Sulphates.
Silver Oxide	Silver Chloride.
Zinc Valerate	Purity.
Sodium Salicylate	Alkaline to litmus.

We call your attention to "A Bibliography of the Deterioration of Drugs and Pharmaceutical Products" by E. G. Eberhardt and F. R. Eldred, Indianapolis, Ind., published in the January issue of the Journal of the American Pharmaceutical Association, 1914; and to the "Purity of Chemicals and Drugs" by H. Englehardt, published in the Journal, 1913, page 163.

We also recommend that you submit all compound formulas to your chemists for their approval. Such a procedure will assure you of having formulas already supposedly therapeutically balanced, further improved by their chemical and pharmaceutical adjustment. All three considerations are necessary to secure an elegant and scientific preparation.

In concluding this report the committee desire to herewith acknowledge to the Association their appreciation for the honor that has been conferred upon them through their appointment to this office.

The chairman likewise desires to thank both Mr. Baker and Dr. Thorburn for their prompt and hearty coöperation in the preparation of this report. Both of these gentlemen have herewith suggested to you, methods that are not only unique but also far superior to those in general practice today.

Franklin Peale Summers,  
A. D. Thorburn,  
W. L. Baker.

## WATER PURIFICATION AT COLUMBUS, OHIO.\*

---

CHARLES P. HOOVER,  
CHEMIST IN CHARGE.

---

Perhaps few cities in the world have had so difficult a public water-supply problem to solve as did the City of Columbus, Ohio.

For years, it had been the practice to pump sewage polluted water from Alum Creek and the Olentangy and Scioto Rivers, into the distribution-system of the city. Even with these sources of supply, the quantity of water available, was not sufficient, and there was constant danger during the summer and fall months of a water famine.

As has been stated, the water was polluted with sewage, and was at times extremely muddy, and, as the water-sheds of the above-mentioned streams are underlaid with limestone rock, the water passing over and through this limestone was very hard. The hardness was so excessive that the water was not satisfactory for domestic or commercial uses. It would not lather freely with soap, and, when used for boiler-feed purposes, it was very injurious to the boilers, due to the large quantity of scale deposited on their tubes. The water was so impure, that severe epidemics of typhoid fever were of frequent occurrence, and Columbus was recognized as having perhaps as high a typhoid-fever death-rate as any large city in the United States. In 1904, just a year previous to the time that work was started on the improved water supply, the typhoid-fever death-rate of the city was 139 per 100,000, a disgrace to any American municipality.

After heavy rains, the water was so turbid or muddy that it was almost impossible to use it for any purpose. The reader will perhaps realize how muddy the river-water really is, by knowing that, after heavy rains, as much as one hundred and twenty-five tons of mud are removed from a day's supply of water before it is pumped to the consumer.

*The Storage Dam:* In order to provide a sufficient quantity of water, a dam was built across the Scioto River about five miles above the city. This dam is a concrete structure 1006 feet long and thirty feet high. The reservoir formed by the construction of this dam, across the river, is 5.8 miles long, has an average width of 500 feet, and its capacity is 1,720,000,000 gallons.

The dam is located about 4.5 miles from the Purifying and Softening Works, and it was planned to build a gravity-conduit from it to the Purification Works, but no money was appropriated for this work, therefore, the river is used as a conduit; the water flowing down the river from the dam to the Pumping Station. The water is then pumped from the river to the Purification Works, and is softened and filtered, then pumped into the distribution-system.

*The Water Purification Works:* These are designed for softening as well as filtering the water, and on account of the extremely variable characteristics of the untreated water, great elasticity was sought in their operation.

---

\*Delivered before the Columbus Branch, December 9, 1911.

The plant comprises primarily:

1. A lime saturator, composed of six tanks, each twenty-five feet square, in which the chemical reactions begin.
  2. Two Baffled Mixing-Tanks, each two hundred and four feet long, twenty-five feet wide and twenty feet deep.
  3. A settling basin divided into six compartments with a total capacity of fifteen million gallons, in which the greater part of the turbidity and precipitated materials are removed by sedimentation.
  4. Ten mechanical filter units, each with a net filtering area of 1089 square feet.
- The above have a normal rated capacity of thirty million gallons per twenty-four hours and in addition there is:
5. A covered, filtered-water reservoir holding ten million gallons.

Included in the plant there are also a storage-house for chemicals and a Head House, in which is placed the equipment for dissolving and feeding the lime, soda-ash and coagulant into the water. The chemical and bacteriological laboratories are also housed in this building.

*Purification with Alum:*—When sulphate of alumina is added to a muddy, alkaline water, the aluminum combines with the alkalinity of the water, and a flocculent, gummy, gelatinous precipitate of aluminum hydroxide is formed. This precipitate entrains the mud and bacteria, and all suspended particles present in the water, and being heavy soon settles. This settling-process, or sedimentation, takes place in large, concrete settling-basins from which the material which settles from the water is washed back into the river, below the in-take.

Only minute quantities of alum are required to properly coagulate the sediment. From one to two grains of alum to a gallon of water, is usually sufficient, unless the water is extremely muddy; then as much as four grains is sometimes required.

There are seven thousand grains in a pound, so that one grain per gallon, is equivalent to one pound in seven thousand gallons of water. Even this small quantity does not remain in the purified water, because, as has already been explained, the alum is precipitated and settles out of the water with the mud and other impurities.

*Softening Water:*—Lime and soda ash are used to soften the water, and during the year 1912, the total hardness of the river water averaged two hundred and twenty-two parts per million, whereas, the average total hardness of the filtered water was only seventy-nine parts per million. At first, the consumers felt that the use of chemicals for softening and coagulating the water, would not be desirable, and had some hesitancy in using the chemically-treated water. This prejudice has been entirely overcome and the people are now beginning to realize that there is less chemical in the filtered water than there is in the untreated river water. The reason that there is less chemical in the filtered water than there is in the river water, being, that the chemicals which are added to the water, in order to soften and coagulate the impurities, combine with the soluble carbonates and sulphates present in the water and form insoluble compounds, which are removed from the water by sedimentation and filtration.

The following paragraph will explain more fully the nature of lime and the reactions which take place when it is added to hard water.

Lime is made by burning limestone in a kiln. Pure limestone has the chemical

formula  $\text{Ca CO}_3$  (Calcium Carbonate). When this is burned, the following reaction takes place:

The difference, therefore, between limestone and lime is that the calcium of the limestone is combined with  $\text{CO}_2$  (carbon dioxide) as a carbonate, and, in burning, the carbonate is broken down, carbon dioxide passing off as gas, leaving the calcium combined with oxygen as an oxide ( $\text{Ca O}$ ).

Lime has a great affinity for carbon dioxide, and when it is exposed or comes in contact with carbon dioxide, the carbon dioxide is immediately absorbed and the lime is converted back to its original state, that is, limestone or calcium carbonate.

All natural, hard waters contain free and half-bound carbon dioxide, and it is the presence of this carbon dioxide, in water, that enables the water to dissolve and to hold in solution, large quantities of limestone.

It is a well known fact, that if hard water, that is, water containing lime carbonate in solution, is boiled, the  $\text{CO}_2$  (carbon dioxide) which it contains, is expelled, and a deposit of lime forms in the bottom of the vessel in which the water is boiled, demonstrating that the limestone is not soluble in water, only in the presence of  $\text{CO}_2$ .

When lime is added to hard water, it absorbs the carbon dioxide present in the water, is, itself, converted back to limestone, and as limestone is not soluble in water in the absence of  $\text{CO}_2$ , it settles out of solution along with the mud and other impurities. The limestone originally present in the water, also is precipitated and settles out of solution as soon as the  $\text{CO}_2$  is absorbed by lime, therefore, the lime added to the water, as well as the limestone originally present in the water, is removed, and the water contains less chemical or mineral matter than it did in its natural condition, and is therefore softer.

Lime will not remove sulphate-hardness, therefore, this condition is removed by precipitating it with soda-ash (sodium carbonate).

It has been learned at the Columbus plant, that the addition of lime not only softens the water, but that the typhoid and other intestinal bacteria, will not live in lime-softened water, because the lime absorbs the carbonic acid from the water, and these disease-producing bacteria will not live in water free from carbon dioxide.

If lime softened water be inoculated with typhoid organisms, they will die out in a period of twenty to twenty-four hours, and if the water be softened to the lowest possible figure with lime, and an additional quantity of lime added, sufficient to introduce a small quantity of excess lime, the sterilization is accomplished in from four to five hours.

*Brief Description of Process:* The water is measured, through Venturi Meters, as it enters the water-softening and purification works. Lime, and soda-ash are added to it in the proper proportions to soften it, and sufficient alum to properly sedimentize it, which are determined by two hour chemical determinations. After the chemicals are introduced into the water, the water so treated, is then passed through long mixing tanks, where the chemicals and water are thoroughly mixed, and the chemical reactions take place. From the mixing-tanks the water passes

into settling-basins, and the mud, bacteria and precipitated limestone are deposited. Practically all of these impurities are removed by sedimentation, but, in order to remove all suspended particles, the clear water from the settling-basins is passed through sand filters. The water passes through the sand, into a large covered concrete reservoir; and from this reservoir is pumped to the distribution system.

*Purity of Filtered Water:*—Columbus has now one of the most modern, fully-equipped water purifying systems of the world.

The water delivered to the consumers is satisfactorily soft, is always sparkling-clear, has a wholesome taste, and is absolutely pure.

During the year 1912, the average number of bacteria present in the river water was nineteen thousand two hundred and ten per cubic centimeter, and the average number in the purified water was only fourteen per cubic centimeter, a reduction of 99.93%. Another evidence of the purity of the water, is the decrease in the typhoid-fever death-rate, which has fallen from one hundred and thirty-nine in 100,000, to about eighteen in 100,000.

---

## THE RELATION OF PHARMACY TO MEDICINE.

---

ALBERT H. DEWEY, PH. G., B. S., M. S.

---

Historically, pharmacy and medicine had a common origin. If we would advance the contention that pharmacy is the mother of medicine, we must at the same time admit that the parent is subservient to its offspring. However that may be, the fact remains that, somewhere in the past there arose the necessity for a separation of the two professions. This necessity was undoubtedly an economic one, which had its foundation deep-rooted in the very nature of the two professions.

The ancient pharmacist, who spent his time in collecting and curing drugs, of both animal and vegetable origin, and making, from these drugs, the various preparations required in the treatment of disease, could not become very highly proficient in the diagnosis and treatment of human ills, crude and imperfect as these arts may have been at that time. Conversely, the physician, who devoted his time to attendance upon and treatment of the sick, had not the time to become skilful in the recognition of the growing plants used in medicine, nor in the art of their preservation and preparation for use.

Hence, the separation of the two professions, was one of the mighty factors that made for the increased efficiency of both. And, right here, it might be pointed out that the more skilful and efficient a physician became, through a conscientious devotion to his work, the more he stood in need of the services of a skilful and efficient pharmacist, while the pharmacist's profession depended wholly upon that of medicine. This mutual inter-dependence of the two professions, without doubt, increased the efficiency of both and its re-establishment in

modern times for the sake of increased efficiency is one of the important questions confronting these two sister professions to-day.

On down through the ages, this division of labor in the interests of economy and efficiency has continued, until to-day we live in the greatest age of specialization the world has ever known.

One factor which has influenced this evolutionary development in pharmacy, more than in medicine, is modern business organization and the influence of large combinations of capital. From the very natures of the two professions, this fact is more applicable to pharmacy than to medicine. For example, a large manufacturing-establishment can make a thousand gallons of a given preparation better and more economically than a thousand individual pharmacists can make a gallon apiece; but neither the application of modern business principles, nor large combinations of capital have yet devised a machine which will perform a thousand appendicitis-operations collectively, more economically or more efficiently than a thousand such operations can be performed individually.

Because of this influence of modern business organization, the processes of pharmaceutical-manufacturing have practically passed out of the hands of the individual pharmacist. And long ago, because of the area from which drugs are collected, market-conditions, and a differential-price for labor, the collection and preservation of drugs had passed out of his hands.

What then remains, at present, as the pharmacist's work? "Compounding and dispensing," if we apply ordinary subtraction to our time-honored definition and scan not too closely the forces that are even now grasping for these.

It is admitted on every hand, that the gross income from the compounding and dispensing of physicians' prescriptions in the average drug store to-day does not exceed ten *per cent.* of the total gross income. The other ninety *per cent.* comes from the commercial end of the drug business, which is, largely, retail merchandising-operations, into which the pharmacist has entered in order to earn a livelihood.

In this connection, it might be pointed out, that the same natural law, which made it impossible for the ancient pharmacist to become proficient in the art of healing the sick, because he devoted his time to the collection and preservation of drugs and their preparation for use, to-day makes it impossible for the pharmacist to become skilled in the real work of pharmacy, because he is assiduously devoting his time to side-line merchandising, bargain-store methods, advertising, window dressing, etc., etc.

This brings up the very important question,— "What is the real work of pharmacy to-day?"

Even as the ancient pharmacist, by intelligent assistance, made the ancient physician more efficient in his work, so it should be the real function of the modern pharmacist, by intelligent assistance, to make the modern physician more efficient in the work that he is endeavoring to do.

With the remarkable amount of research that is constantly being carried on in the field of medicine, there is, inevitably, a broadening of, and in many cases, fundamental changes, in our knowledge of the nature and cause of disease. This progress and development in medical knowledge, mean corresponding changes and progress in the treatment of the disease.

Not many years since, if the physician desired an infusion or decoction, an ointment or emulsion or pill or any thing else, well prepared, for the treatment of a patient, he turned to his reliable helper, the pharmacist, and received an efficient and potent preparation. To-day if he desires a blood-count, a urinalysis, a gastric- or fecal-analysis, an autogenous vaccine, a Widal or Wasserman test, or any one of a long list of things, which the physician in most cases must delegate to some one else, does he turn to the pharmacist? And if not, why not? Simply because the pharmacist of to-day is neither equipped, nor prepared, nor competent, to do this kind of work. He is too busy selling tin watches and sugar-coated prunes: his mind is on the weighty problems of how to compete with the chain-store or the copy for his next week's cut-rate advertisement. While the physician has been learning new facts about disease, leading to new methods of treatment, the pharmacist has been adding side-lines. There is no reflection in pharmacy of the changes and progress occurring in medicine.

As before indicated in this paper, a man becomes most efficient in that to which he devotes his time, his energy, and his attention. The commercial pharmacist who devotes his time and attention almost wholly to the problems of the business world, can be of but little professional assistance to the physician. The physician who devotes himself to his practice, cannot continue to be an efficient and reliable laboratory-worker, and yet this laboratory-work must be done and done well, if the physician is to do full justice to his patient and to himself.

There are many things in the diagnosis and treatment of disease to-day that, for a variety of reasons, the average modern physician cannot do for himself, but must delegate to some one else to do for him. Who is to do this,—the physicians' "delegated work"? We may admit that the physician who has at his command the services of an educated, experienced, competent, reliable laboratory-worker, in a thoroughly equipped laboratory, is a far better and more efficient physician than he would be without such assistance. If we admit, also, that such a laboratory-worker will increase the efficiency, not only of a given physician, but of every physician who will avail himself of the opportunities of such assistance, then we may catch a glimpse of the tremendous uplift that such a class of men could give to the medical profession.

Nobler, holier, more useful work was never entrusted to human hands than the medical profession is doing to-day in its efforts to stamp out human disease. To have had part, however humble, in such a work, is a rare privilege and worthy of any man's ambition and his life's best efforts. And yet, we find this field almost wholly unoccupied, with not a single university, or college of medicine, or college of pharmacy, fitting its graduates to do this most useful, necessary and important work.

This feature of the situation could undoubtedly be overcome, but another feature, less easily provided for, is the question of legal registration for the practice of such a profession.

I believe it is an indisputable fact, that the men now registered as pharmacists or those who may hereafter become registered under our present pharmacy laws, are not and will not be qualified for this kind of work. Graduates of our pharmacy colleges are not excepted in this statement.

The purpose of registration as a legal pre-requisite for the practice of any

profession, is, we may assume, two-fold in its nature. First, it would protect the public against incompetent and inefficient practitioners, and second, it would protect the qualified practitioner against the unjust and unfair competition of the unqualified practitioner.

If it is ever hoped to raise up a reliable and competent class of professional men who are capable of being a real help to the medical profession, the individual must have the protection of registration upon a plane high enough to actually protect him against the competition of unqualified men.

Elsewhere I have referred to the pharmacist of to-day as a commercial pharmacist and I should like to make clear, my idea of the distinction between the commercial pharmacist and the professional pharmacist. The commercial pharmacist practices a kind of pharmacy which is wholly independent of the medical profession, while the professional pharmacist practices a kind of pharmacy which is wholly dependent upon the medical profession. To be sure, these two kinds of pharmacy are hopelessly mixed in the drug store of to-day and, united with them, is a miscellaneous lot of retail merchandising, that bears no relation *whatsoever to any kind of pharmacy*. But the fundamental distinction between commercial and professional pharmacy, is their relationship to the profession of medicine. Whether professional pharmacy,—and that means the physicians' delegated work, and, practically, that means the prescription-business,—can ever be separated from the "hodgepodge" we now call the drug business, is a question, but it, undoubtedly, belongs with the rest of the physicians' delegated work, in the hands of a well-educated, well-equipped, competent, reliable man, who for lack of a better term, we may call a professional pharmacist.

---

### ATROPA BELLADONNA.\*

---

BERTILA OTT, PHAR. B.

---

*History*.—Atropa Belladonna is the subject of many legends and how it came by its name is interesting to know. Atropa (Greek, Atropos) was the eldest sister of the Three Fates, who were worshipped by the ancient Greeks and were supposed to preside over accidents and events; to determine destiny; and the period of human life. Their names were Clotho, spinner of the thread of life; Lachesis, the second, who twisted it and under whose fingers it was made now strong, now weak;—

"Twist ye, twine ye! even so  
Mingle shades of joy and woe,  
Hope and fear, and peace, and strife,  
In the thread of human life."

Atropos, the third sister—"the inflexible," the fate that cannot be avoided—armed with a pair of shears remorselessly cut short the thread of life. Belladonna from the Latin (Bella) Handsome, (Donna) Lady—so named because Italian

---

\* Read before the Cincinnati Branch A. Ph. A.

ladies used a cosmetic made from the berries, and the Spanish ladies used preparations made from this plant to dilate the pupils of their brilliant eyes.

In many parts of Southern and Central Europe and in some parts of Asia, flourishing in shady places, growing by old walls or thriving amongst rubbish heaps—may be found this herbaceous, perennial plant, of the Solanaceæ family, three to five feet high, known as the “deadly nightshade.” It has merited its ominous name from the dire effects it produces on any human being who ventures to eat any portion of it.

The wide-spread distribution of the plant made its properties known to the inhabitants of most countries, and although no definite mention of it can be traced in ancient literature it is reasonable to suppose that it was well known to ancient peoples. Theophrastus, the pupil and successor to Aristotle, describes under the name Mandragora, a plant closely resembling belladonna, and Dioscorides is said by some to mean the same herb in the plant he names Strychnos-manicos.

There can be no doubt that its poisonous properties were utilized in the good old days—though seldom referred to as a remedy. For the past two centuries it has been pretty regularly mentioned by all those who wrote comprehensively on medicine, and more or less used, but never so common until its usefulness in the examination and treatment of the eye, opened for it a new and important field. It has been a panacea among Homeopaths and a specific with the Eclectics since the foundation of their schools. In “regular medicine” belladonna has a more recent introduction, due to the well-known pharmacist, Mr. Peter Squire, of London, who about 1860 commended it as the basis of a useful liniment, for the relief of neuralgic pains. At the present time it is considered one of the most important items of our *Materia Medica*.

*Description:*—The plant flowers in June and July. In September its livid, purple, bellshaped, flower gives place to shining, purple black fruits or berries, luscious in appearance and sweet to the taste. These berries have been eaten by children while playing in fields and lanes and in most instances with most unfortunate results. All parts of the plant are active. The parts directed for use by the U. S. and Br. Pharmacopœia are the leaves and the root. Leaves should be collected when the plant is in flower, roots from plants three years old or more, collected in autumn. Leaves which have been kept long should not be used, as they undergo changes through absorption of atmospheric moisture, emitting ammonia and probably losing a portion of their nitrogenous matter.

Our U. S. P. directs us to use leaves of the following description: “Usually of a dull-brownish color, the leaves much wrinkled and matted together, frequently with the flowering tops intermixed; leaves from 6 to 20 cm. long; 4 to 12 cm. broad; broadly ovate; apex acute; margin entire; narrowed into the petiole; upper surface brownish-green, lower surface grayish-green; epidermis more or less papillose; particularly on the under side, odor distinctly narcotic, especially on moistening; taste somewhat bitter and acrid. The powder is characterized by few hairs and numerous, small arrow-shaped crystals of calcium oxalate. Leaves when assayed by the U. S. P. process should yield not less than 0.35% of mydriatic alkaloids. The dried roots of not less than 0.5% of mydriatic alkaloids.

Roots described as follows: Of cylindrical or somewhat tapering, longitudinally, wrinkled pieces 1 to 2.5 cm. thick, the bark somewhat incurved at the edges of roots, which have been split before drying; externally brownish-gray, dusty or mealy; outer layers of the periderm rather soft; frequently abraded and thus showing lighter patches; fractures nearly smooth, mealy and emitting a characteristic puff of dust; internally whitish; the older roots showing medullary rays near the bark; nearly inodorous; taste sweetish; afterwards bitterish and strongly acid. Roots that are shrunken, spongy, dark-brown and free from starch should be rejected as also old woody roots and stem-remnants. Microscopical examinations of belladonna root shows bark rather thick, free from bast fibers, composed almost entirely of parenchymatous cells, more or less filled with starch grains and calcium oxalate raphides.

In various parts of Europe both the leaves and the root of belladonna are adulterated with the similar products of a *Phytolacca*, which has been variously supposed to be the *Phytolacca Decandra* of North America, which has become naturalized in Southern Europe. The leaves and general appearances resemble those of belladonna, but are to be recognized by their upper surfaces being without hairs and brighter than in the belladonna plant. The dried *phytolacca* root resembles superficially that of belladonna, but may readily be distinguished by the epidermis not being easily abraded with the finger nail. The histology of the root is characteristic, the raphides are acicular instead of being as in belladonna, sandy crystals, and the root itself is generally characterized by the alternating distinctly separate rings of wood and bast tissue.

Attention has been called to the species of *Scopola*, a genus connecting *atropa* and *hyoscyamus* as resembling belladonna. The rhizomes of the *Scopola Carniolica* are very similar to the roots of belladonna, the bark, however, of the former is less thick. *Scopola Japonica* (Japanese Belladonna) was found to be similar to *Scopola Carniolica*. This drug is official under *Scopola*.

*Active Principles*.—The active principles upon which the medicinal repute of belladonna depends are atropine and hyoscyamine-alkaloids possessing the same chemical formula ( $C_{17}H_{23}NO_3$ ), but differing somewhat in therapeutic properties. The close connection of the alkaloids suggest that it would be difficult to obtain one free from the presence of the other, and as a matter of fact, the official atropine allows a small amount of hyoscyamine. The melting points of these two alkaloids differ—the most reliable test, however, is dependent upon the fact that while a solution of hyoscyamine is capable of rotating the plane of polarisation of a ray of light to a considerable degree, pure atropine is optically inactive. Investigations undertaken at the request of the Schering manufactory to determine why the proportion of hyoscyamine and atropine in a root seems to vary with the method of working, reached the surprising conclusion that the optically active hyoscyamine can be changed into the optically inactive atropine under a variety of circumstances such as fusion, action of weak soda solution (even at ordinary temperature), and of ammonia. Other existing alkaloids of belladonna are belladonnine, hyoscyne and atropamine, besides the usual vegetable constituents, such as albumen, gums, etc., and a coloring principle named atrosin. Belladonna has been studied by Vanquelin and many chemists after him, but it was not until 1833

that atropine in a state of purity was isolated from it. This was accomplished simultaneously by Geiger and Hess, two German chemists, and Mein, a German pharmacist.

*Preparations:*—Pharmaceutical preparations of the leaves are Extract Belladonna and Tincture Belladonna. From the extract we prepare the U. S. P. plaster and ointment. The extract is also a constituent of Co. Laxative Pills, and of Podophyllum, Belladonna and Capsicum Pills. Of the root we have Fl. Ext. Belladonna and Belladonna Liniment. Other official products are Atropine, Atropine Sulphate, Oleate of Atropine and Homatropine Hydrobromide.

*Uses:*—Belladonna is one of the most useful agents in the materia medica, ranking high in its efficacy and its wide range of usefulness. The most important uses of atropine or belladonna are:— (1) In the form of a belladonna plaster or liniment atropine or belladonna, it is used to relieve pain on the area where it is applied. (2) As a cardiac and respiratory stimulant especially where immediate effects are desired. (3) As an antidote for morphine poisoning, and it is often given with morphine to avoid poisonous effects. (4) Atropine is used to dilate the pupil, so that the retina or background of the eye may be more easily examined and to prevent adhesions between the iris and lens, when the iris is inflamed. (5) Atropine is often given to check secretions, for example, profuse perspiration, etc.

*Symptoms of Overdoses:*—Symptoms of overdoses are dryness of the mouth and throat; redness and dryness of the skin, pulse and breathing rapid; pupils widely dilated; great restlessness, followed by delirium. The delirium is peculiarly wakeful, active and talkative, the excessive excitement is followed by a deep sleep, which gradually becomes deeper (stupor).

*Antidotes:*—As antidotes give evacuants (emetics and cathartics), tannic acid; keep body warm; give artificial respiration if the breathing is embarrassed. Give heart and respiratory stimulants, such as whisky, caffeine, strychnin, etc.

A recent writer on Materia Medica advises us *not* to give morphin, for while atropin is the antidote for morphin, the dangerous effects of atropin are due to the exhaustion of the breathing. If morphin is given in such cases, the breathing is only made slower. Morphin, therefore, is not an antidote for atropin, though atropin is an antidote for morphin.

*Cultivation:*—Having reviewed this most interesting plant, let us, but for a few moments consider its cultivation. Until recently the manufacture of belladonna preparations was carried on exclusively with wild plants, gathered in a somewhat haphazard fashion by herb collectors. When the scientific cultivation of medicinal herbs on a large scale was introduced, many critics declared that wild belladonna was superior in alkaloidal strength to that of the cultivated variety, but manufacturers at home and abroad, upon investigating, have shown that this fear is groundless, results showing that a plant of much greater alkaloidal strength than what our U. S. P. demands may be obtained.

Since belladonna is not an indigenous plant, present war conditions have opened our eyes, as to the future supply, and great necessity of home production or cultivation of this plant, and we are glad to note what is being done to conserve this wonderful drug. Pioneer among those who have introduced the scientific cultivation of belladonna in the U. S. are Johnson & Johnson of New Brunswick,

N. J. Their experiments have led the way to a higher grade of belladonna, to any that has heretofore been known. Their farms comprise fourteen acres, at the above-mentioned city, a fairly large one at Conshohacken, Pa., near Philadelphia, and forty acres at Salinas, Calif. The work of Johnson & Johnson in the culture of the belladonna plant, has aroused worldwide interest, and this interest is just now being revived. During the years which have passed extended experiments have been made as to the influence of soil, climate, fertility upon the plant and the yield of the alkaloid. The researches of Johnson & Johnson upon the cultivation of belladonna in the United States have been most varied and extensive, a considerable amount of which has been published for the benefit for all interested therein. Incidentally it might be mentioned that this work is enormously extensive and as yet they have not been able to supply their own demands. But they are glad to make their contribution to American materia medica, and they believe the experience they have gained by the contribution to the knowledge of such an important plant as belladonna will compensate them for their outlay. We hope that in the near future their efforts may be rewarded with an abundant supply of this drug so as to also make a financial success. By coöperation with other nations the U. S. Department of State, through its consulate service and the Department of Agriculture, through its Bureau of Plant Industry, bring out and put at our disposal much valuable information about the growing of foreign plants.

Among others the U. S. Department of Agriculture at the Arlington Experimental Farm, Virginia, is carrying on interesting work in regard to the breeding of plants, in order to obtain a type of belladonna plant, fairly constant in the yield of its alkaloids. Observation work is also carried on by Parke, Davis & Co. of Detroit, Mich., Eli Lilly & Co. of Indianapolis, Ind., and a firm of Glenolden, Pa.

Among the schools of pharmacy which have undertaken the cultivation of medicinal plants so as to facilitate and make more comprehensive the study of pharmacy and pharmacognosy, we would mention the Minneapolis College of Pharmacy and the Philadelphia College of Pharmacy.

We consider the appeal to pharmacists by Mr. Kilmer, in the October issue of the "Practical Druggist," should receive deep consideration where he says:—"It is the duty of the pharmacist to supply the materia medica needed for the alleviation of disease, and especially those which he can grow or otherwise produce for himself. If we could thus multiply and extend the cultivation of medicinal plants among the thousands of druggists in the United States, we would soon find ourselves independent of other sources of supply."

"Here, then, is our opportunity and our duty to protect and conserve the supply of drugs and medicines against existing influences and such as may come upon us in the future." In fulfilling our duty we will be able to supply ourselves with a quality of crude drugs which will yield for us the purest and best preparations.

*Bethesda Hospital, Cincinnati.*

## THE WAR AND DRUG IMPORTATIONS.\*

---

HARRY B. FRENCH, PRESIDENT SMITH, KLINE & FRENCH CO.

---

When war broke out between the European nations, commerce for a time was paralyzed. There were hundreds of German ships on the high seas as well as a number of Austrian ships. These vessels were all liable to capture as soon as they left neutral waters. Up to that time they had been doing a very large portion of the carrying trade, especially from China and Japan and from Germany to North and South America. Moreover the ships of the *Triple Entente* were not safe so long as there were a number of German cruisers scattered over the different parts of the world. That these cruisers have given a good account of themselves is shown by the fact that there have been nearly two hundred vessels of the *Triple Entente*,—that is vessels belonging to France, Russia and England,—that have been captured.

The immediate result of the breaking out of the war was the seizure of many of these vessels in transit, the holding up in the ports of one of the belligerents of merchant vessels belonging to an enemy, and the detention in neutral ports of many other vessels. This for a considerable time prevented the forwarding and the delivery of the merchandise, and produced for the time being a great scarcity of goods.

After a few weeks it was found that merchandise could be imported, though roundabout routes had to be taken, but there were great delays in shipments, and the goods were still liable to seizure by an enemy. German chemicals in considerable quantities were shipped through Switzerland and from the Port of Genoa, and through Christiana, Sweden, Copenhagen, Denmark, but mostly through Rotterdam. Crude drugs came more largely through the southern ports of Europe.

At the present time most of the heavy chemicals can be bought at prices almost as low as prevailed before the war, but the goods must be paid for by sight draft. Crude drugs in many cases can be bought at lower prices than before the war, but there is great difficulty in obtaining shipments, owing to the difficulty in making payments. In many cases the money has to be sent abroad and trusted to the honesty of the shippers. For instance, in having goods shipped from Trieste, we found it necessary to have our bankers here cable the money to a correspondent in Milan, Italy. The correspondent sent the money to the merchant in Trieste. This method is not entirely acceptable because it places the buyer entirely within the hands of the seller, besides being expensive in other ways.

The position has been complicated in recent weeks by the entrance of Turkey into the war. This directly affects such articles as Opium, Tragacanth, Aleppo Nutgalls and Colocynth from Syria, and it also affects Gum Arabic from Egypt. The effect on Gum Opium has been lessened by the large stocks held in this country in bond, and by the fact that Persian gum can be substituted for manufacturing purposes. If, however, there should be a Mohammedan uprising, all these

---

\* Read before the Philadelphia Branch at its December meeting.

articles would be even more seriously affected, as well as many others. As it is, Persia is now in a very disturbed state.

If the war continues it is thought there will be a material advance in the price of Gum Opium and there should be also a corresponding advance in the price of its derivatives, especially Morphine and Codeine. Shortly after the Turkish war broke out and when it was fully expected that Morphine and Codeine would advance, the prices were reduced. This was a very unfortunate step, for the reason that it lessened the value of the stock on hand of all dealers in Morphine and Codeine, all tablets and pills and other preparations made from these salts. The reduction was not based on conditions or on supply and demand, but simply and solely from an antagonistic feeling that had grown up between certain powerful manufacturers. From the consideration of this unjustifiable action, dealers must reach the conclusion that they cannot base their operations on the ordinary laws of trade, such as supply and demand, as such laws may be affected by the war conditions, but they must also take into consideration the jealousies of different manufacturers, who evidently will not hesitate to cause much loss to their customers and will not hesitate to make it impossible for such customers to use their business experience and sagacity. We have no hesitation in condemning this reduction in the price of Morphine and Codeine as unjustifiable, either on the grounds of policy, of conditions, or of morals.

At the present time, it is somewhat easier to obtain goods and they are coming here in larger quantities, but there are such uncertainties and delays in shipments that at one moment the market is flooded with arrivals and later is bare of stock. In many quarters it is thought that the chemicals and the crude drugs that are being shipped to this country are from accumulated stocks, and that later when these stocks become greatly depleted, much higher prices will prevail. This is undoubtedly true of some goods, but it is hard to tell whether it will apply generally. For instance, a remark was made some time ago that Germany had a population of sixty-five millions of people and that about five millions of these had been taken from their ordinary occupations. This, however, left sixty millions of people to carry on the work of the sixty-five millions. Of the five millions taken from their occupations, many of them were trained for special work and their places cannot be filled. You must remember, however, in Europe the women are accustomed to work and it is problematical how much of this work left undone by the five millions taken away, can be done by the sixty million people. The writer's opinion is that if the channels of trade are free from hindrances such as now prevail, that merchandise, whether in the form of manufactured products or of crude drugs will be obtainable to a greater or less extent. Every month, however, that the war is prolonged must increase the economic loss, resulting from the increased destruction of men, of countries ravished by the contending armies, and also from the cessation of productive work. It is probable that the next two or three years this country will see great prosperity, as the demands of the combatants upon the resources of this country will be greater than formerly, and they must be paid for, however great may be their deprivation in other respects. It is certain, however, that no such tremendous

loss of life and material can take place, as has now taken place in Europe, without disastrous results being felt by every country in the world for many years to come, though it may be two or three years before the reaction begins to be felt in this country.

At the breaking out of the hostilities, the question of method of conducting our business had to receive immediate consideration. There were two methods to be pursued. One method was to hold down prices but to refuse to fill orders, or to fill only a very small percentage of orders. The other was to fill all orders that came into the house and advance prices so far as might be necessary because of the increased cost of replenishing stock. This last course was the course followed by the house I represent. Our thought was that we were in business for filling orders of our customers at the market prices. For instance, the manufacturers did not advance their price beyond 70 cents per pound for Citric Acid, but could only fill a very small portion of the demand. The larger portion of Citric Acid sold by houses like ourselves was bought from second hands and imported from Europe. At one time the price advanced in Philadelphia as high as \$1.35 per pound and in New York to \$1.85 per pound. Large buyers paid as high as \$1.20 or more in order to fill such orders. Some unjustifiable criticism was raised by this course of procedure by those houses that quoted prices but refused to deliver goods. There were certain manufacturing houses that sent their price lists all over the country quoting low prices for their chemicals and absolutely refusing to sell a dollar's worth of many of the articles that they quoted. This produced a great deal of confusion and unjustifiable recrimination. Some wholesale druggists quoted low prices throughout the country on articles like Citric Acid, but when they received an order for five or ten pounds would send one pound only. Their prices, therefore, did not represent the market, as the market price is the price that will obtain the goods.

The rulings affecting shipments abroad are very interesting. For instance, our Government has taken the position, as I understand it, that any nation can give its own definition of contraband and act upon that definition. That if the Government of the United States should ship contraband goods to a belligerent, it would commit a hostile act against the enemies of that particular power. That if an individual should make such a shipment, he would also commit a hostile act against the enemies of the power to whom he made the shipment. The Government, however, is not compelled to restrain such shipments, but if such shipments are seized the shipper cannot claim the protection of the Government. I think possibly that many citizens have wondered why it is that this Government permitted England to stop ships, flying an American flag or a neutral flag, on the high seas, condemn certain portions of their cargo and take them into their own ports. It will be interesting to remember that a British ship, sailing from England to the Island of Nassau, one of the British possessions, was seized when about 150 miles from Nassau, during the War of the Rebellion, by an American man-of-war and was condemned by a prize court in New York City. Later the vessel was released, but the cargo was condemned as being ultimately destined to the Confederacy. Our Government acted on the principle that the ultimate destination of the cargo was the point at issue, and that this was not affected by the fact

that the cargo might be shipped first to a neutral port and transferred by several different vessels. Apparently England and France have the right to declare anything contraband that they may wish, but they are probably restrained because of the danger of inciting hostile feeling in this country.

The following prices have been taken from "The Oil, Paint and Drug Reporter" of New York. We give the prices of the articles mentioned before the war, on September 1st and on December 1st. This table shows some of the variations of prices:—

	Before War.	September 1st.	December 1st.
Atropine Sulphate .....	\$ 8.00 oz.	\$35.00 oz.	\$18.00 oz.
Salicylic Acid .....	.25 lb.	1.15 lb.	.70 lb.
Adeps Lance, Hydrous.....	.17 lb.	.80 lb.	.22 lb.
Tartaric Acid.....	.30 lb.	.75 lb.	.42 lb.
Citric Acid.....	.55 lb.	1.25 lb.	.60 lb.
Salts of Tartar.....	.08½ lb.	.25 lb.	
Potash Permanganate.....	.10 lb.	.75 lb.	.14 lb.
Quinine .....	.26 oz.	.31 oz.	.26 oz.
Cod Liver Oil.....	19.00 bbl.	29.00 bbl.	20.00 bbl.
Benzoic Acid.....	.26 lb.	2.00 lb.	.40 lb.
Quicksilver .....	.54 lb.	1.10 lb.	.75 lb.
Juniper Berries.....	.03½ lb.	.22 lb.	.04½ lb.
Camphor, Japanese.....	.42 lb.	.95 lb.	.41 lb.
Hyoscine Hydrobromide.....	21.00 oz.	120.00 oz.	43.00 oz.
Canary Seed.....	.06 lb.	.14 lb.	.07 lb.
Celery Seed.....	.20 lb.	.40 lb.	.16 lb.
Japan Wax.....	.10½ lb.	.22 lb.	.10½ lb.
Belladonna Leaves.....	.60 lb.	2.25 lb.	1.10 lb.
Dandelion Root.....	.15 lb.	.70 lb.	.25 lb.
Cumarin .....	3.10 lb.	12.00 lb.	3.25 lb.
Hydrochinone .....	.51 lb.	8.00 lb.	1.50 lb.
Potash Bromide, Gran.....	.37 lb.	.74 lb.	.74 lb.
Carbolic Acid.....	.08½ lb.	.70 lb.	.55 lb.
Caustic Potash.....	.05 lb.	.32 lb.	.08 lb.
Potash Prussiate, yellow.....	.13 lb.	.30 lb.	
Homatropine Hydrobromide.....	12.00 oz.	135.00 oz.	85.00 oz.
Phenolphthalein .....	1.05 lb.	2.00 lb.	1.25 lb.
Sodium Cacodylate.....	3.50 lb.	18.00 lb.	6.00 lb.
Thymol .....	1.80 lb.	12.00 lb.	5.50 lb.

## REVIEW OF CURRENT PHARMACEUTICAL LITERATURE.\*

FREEMAN P. STROPP, PH. M.

The abstracts herewith given are from the November numbers of several publications and are few in number, for, much to the writer's surprise, he found very few original articles of much real interest to the average pharmacist, that might be considered as being at all scientific. There were many articles on commercial topics and of academic interest, and many of the journals had reprints

\* Read at the December meeting of the Philadelphia Branch.

of excellent papers, and a considerable number contained a large number of abstracts from excellent articles, some from foreign and others from domestic journals.

#### MERCK'S REPORT.

*Objectional Labeling for Medicinal Preparations:*—The U. S. Department of Agriculture, through the Bureau of Chemistry, has issued a number of suggestions to makers and proprietors of medicinal preparations to be followed by them in avoiding conflict with the provisions of the amended Food and Drugs Act, and has given examples of the kind of advertising that would bring them into danger of prosecution as violators of the law. Some of the suggestions follow:—

"A preparation cannot be properly designated as a specific, cure or remedy, or recommended as infallible, sure, certain reliable or invaluable, or bear other promises of benefit unless the product can, as a matter of fact, be depended upon to produce the results claimed for it."

"Not only are direct statements and representations of a misleading character objectionable, but any suggestion, hint or insinuation, direct or indirect, or design or device that may tend to convey a misleading impression should be avoided."

"Representations that are unwarranted on account of indefiniteness of a general sweeping character should be avoided."

"Testimonials, aside from the personal aspect given them by their letter form, hold out a general representation to the public for which the party doing the labelling is held to be responsible. The fact that a testimonial is genuine and honestly represents the opinion of the person writing it does not justify its use if it creates a misleading impression with regard to the results which the medicine will produce. No statement relative to the therapeutic effects of medicinal products should be made in the form of a 'testimonial' which should be regarded as unwarranted if made as a direct statement of the manufacturer."

"Statements on the labels of drugs guaranteeing them to cure certain diseases or money refunded may be so worded as to be false or fraudulent and to constitute misbranding. Misrepresentations of this kind are not justified by the fact that the purchase price of the article is actually refunded as promised."—*November, 1914, p. 283.*

#### JOURNAL OF AMERICAN MEDICAL ASSOCIATION.

*Ventilation Theories Exploded:*—The November 7th number of the above-named journal contains a symposium of papers on the subject of ventilation of hospitals, public halls and other places where numbers of people are brought together that proves about as surprising to many individuals as did Dr. Hatcher's paper on digitalis, reported for this meeting in October by Prof. LaWall, and for much the same reasons, namely, that they show the incorrectness of many of the ideas long held with reference to the subject. Very careful investigation has demonstrated that:—

1. The amount of oxygen, which in pure air amounts to 21%, may be reduced to 17% before the air becomes really harmful to breathe, yet rarely does it get lower than 20% in so-called poorly ventilated rooms.

2. Carbon dioxide in amount exceeding .04% has often been stated as being dangerous, but exhaustive experiments have shown that the amount may run over 1% without proving harmful, yet rarely does it exceed 0.4%, even in crowded rooms.

3. Odors do not necessarily indicate a poisonous condition of the air, and it is becoming generally well recognized that bacteria floating in the air are relatively unimportant as a source of disease, or at least of danger.

4. The depressing effects produced on individuals by the air of crowded or poorly ventilated rooms is due primarily to too high a temperature, to excessive humidity and to a lack of air circulation. Air low in oxygen content and high in carbon dioxide content, but kept in motion, is far less depressing than pure air not in motion.

Frederic Bass says that ventilation systems should aim to secure proper temperature, humidity regulation, keep air in motion and properly distributed, and prevent offensive odors from circulating.

The original articles and an editorial on the subject are well worth reading.

#### AMERICAN JOURNAL OF PHARMACY.

*Germination of Belladonna Seed:*—A. F. Sievers of the Bureau of Plant Industry, U. S. Department of Agriculture, reports the results of a series of experiments.

"The subjection of belladonna seed to freezing temperature accelerates their germination. Hence it is of benefit to sow the seeds in the fall."

"There seems to be no relationship between the size of the seed and its germinating power."

"The heavy seeds are by far the best."

"Color seems to be no criterion of the value of the seed as regards germinating power."

"Treatment of the seed with various strengths of sulphuric acid from one to sixty minutes did not appear to be of any great value."

"Treating the seeds with hydrogen peroxide was found to be of very material benefit."

"Scratching the seed coats, while of some benefit, was not nearly as beneficial as the peroxide treatment."—*November, 1911, p. 483.*

#### JOURNAL OF INDUSTRIAL AND ENGINEERING CHEMISTRY.

*Determination of Camphor and Certain Essential Oils when in Solution in Alcohol:*—W. B. D. Penniman and W. W. Randal describe a rapid method. A definite volume of the solution is put into a Babcock bottle with a solution of calcium chloride and the mixture whirled; a definite volume of gasoline is added and the contents of the bottle again whirled; calcium chloride solution is added to bring dividing line to zero mark on neck of bottle, and a calculation is made from the volume of gasoline solution. Gasoline boiling between 40° and 60° C. is used. Good results were obtained from alcoholic solutions of camphor, oils of peppermint, lemon, orange, anise, nutmeg, cloves and wintergreen.—*November, 1911, p. 926.*

#### NORTH DAKOTA AGRICULTURAL EXPERIMENT STATION BULLETIN.

*Examinations of a Number of Samples of Spirit of Camphor:*—About 125 samples were obtained from various sources, examined and the results tabulated for easy reference.

When the spirit is made by the U. S. P. process it contains 86% alcohol and 10% camphor. Of the lot examined one had only 53% alcohol, the others ranged between 71% and 93%, most of them running about 90%. One ran as high as 18.6% camphor, the others ranged between 6.8% and 12.7%, most of them ranging between 8.7% and 10.3%.—*November Special Bulletin, No. 12.*

#### THE DRUGGIST'S CIRCULAR.

The War Stamp Tax is thus commented upon:—"It is plain if the manufacturer does not pay the tax it will fall upon the retailer and it therefore behooves the latter to act accordingly."

Another editorial makes plea for support of the Stevens bill.

"An Improved Method of Testing Urine for Acetone," by F. E. Niece, a valuable paper, and "Big Things in Pharmacy," a paper of much interest treating of the scientific progress of our calling, are two good articles in this issue.

#### AMERICAN JOURNAL OF PHARMACY.

"*Belladonna and Hyoscyamus*" is the title of a paper by E. L. Newcomb, which is begun in this issue.

"*Commercial Papain*" is the subject of an interesting paper by F. N. Heyl, C. R. Caryl and J. F. Staley.

"*Pure Drugs and the Public Health*," by M. I. Willbert, Ph. D., is the title of an interesting paper.

#### CHEMIST AND DRUGGIST.

"*A New Beta-naphthol Reaction*" is described as follows:—A few drops of concentrated sulphuric acid are added to 1 cc. of diluted beta-naphthol solution, and to this is added 0.05 cc. of a 0.01 per cent. solution of sodium nitrite, when the above coloration is obtained. The reaction is sensitive in a solution containing 0.0002 per cent. of beta-naphthol. The coloration is supposedly due to a quinonoid derivative of beta-naphthol.

#### JOURNAL OF THE AMERICAN PHARMACEUTICAL ASSOCIATION.

An editorial comments on a recent bulletin of the Bureau of Chemistry which speaks of the importance of determining exactly the activity of digestive enzymes and ferments.

#### THE BULLETIN OF PHARMACY.

"*Should the Salesman in Front or the Prescription Clerk in the Rear Receive the Higher Salary?*" is an interesting symposium upon this question.

## THE AMBULANCE CONSTRUCTION COMMISSION.

This is the first great war in which field motor-ambulances have been extensively used. It was inevitable that many defects should be found in existing types, and in various quarters experts began to ask whether something could not be done to standardize the patterns and to improve the type. At the instance of Mr. Henry S. Wellcome the founder of the Wellcome Bureau of Scientific Research, a Commission has been formed, and the names of members show at once that the matter is regarded as of first importance by those most intimately connected with the welfare of the wounded soldier.

Sir Frederick Treves, whose long experience and distinguished service specially fit him for the task, has consented to be the Chairman. The Admiralty is represented by the Director-General of the Medical Department, R. N., while the Quarter-Master-General to the Forces and the Acting Director-General, Army Medical Service, represent the War Office. The British Red Cross Society is, of course, represented by Sir Frederick Treves, and the St. John Ambulance Association by Sir Claude Macdonald and Sir John Furley. The remaining members are all experts. This Commission will first and foremost act as a judging committee for the award of prizes of the value of £2000 provided by the Wellcome Bureau of Scientific Research. These prizes are offered for the best designs of an ambulance-body which shall fit a standard pattern motor-chassis for field motor-ambulances. The last day for the receipt of competing designs is June 30, 1915. It is hoped that the competition will bring in a number of ingenious designs, from which the ideal field ambulance-body will be evolved.

It may be asked why the competition is restricted to designs for a body and not for the complete ambulance, including a chassis. The reason is that a chassis takes much longer to build than a body, and that, when war breaks out, it is impossible to get at short notice anything like a sufficient number of any one type of chassis. On the other hand, a standardized body to fit any chassis of approved dimensions can be constructed in numbers at comparatively short notice. And a perfected body is badly wanted to ensure complete comfort for the wounded.

It is hoped that the information obtained by the competition, and in other ways, will be published in some permanent form, available for future reference. Probably in addition to one design of special excellence, there will be submitted various ingenious suggestions which may be incorporated in the pattern design approved by the Commission. For these, a portion of the prize-money has been set apart. The first prize is of one thousand pounds, the second of five hundred, and the third of three hundred pounds. All details of conditions may be obtained from the Secretary, the Ambulance Construction Commission, 10 Henrietta Street, Cavendish Square, London, W. The competition is open to citizens of all nations.

## SOME FACTS CONCERNING DRUG IMPORTATIONS.

---

H. H. RUSBY, M. D.

---

In the January number of the JOURNAL, Mr. J. W. England contributes a noteworthy article on "Drug Importations." With Mr. England's general conclusions and claims, as there outlined, I am in full accord. Too much care cannot be taken, either to insure uniform findings at different ports and at the same port on different occasions, or to give the importer the fullest opportunity of having the merits of his case sifted until the truth is established. On the other hand, there are statements in Mr. England's article that have no basis whatever in fact, and there are others which can be justly weighed only in the light of existing conditions to which he makes no reference. On page 57 he says:—"It is manifest that such a system gives a large scope for the use of personal influence and offers the possibility of gratifying private grudges. It is not asserted or intimated that any of the officials of the ports of this country are guilty of such nefarious practice, but it is certain that the system encourages such practice." It is a fact that the system in operation at the ports of entry of this country is devised to prevent the analyst from knowing anything about the personal or firm relations of the articles examined. It is very likely that at small ports, where little business is done and where very few persons are employed, such knowledge incidentally reaches the analyst, but this is not a design in the establishment of the methods. I presume that my own case does not differ materially from that of others at the larger ports. I have probably examined more than half of the crude drugs that have entered the United States during the last few years, and I have probably not known anything of the shipper, consignee or owner of a dozen shipments that I have thus examined. In case of the few exceptions, the knowledge has come to me purely by accident. If, after the signing and filing of my certificate a protest is made, such knowledge necessarily reaches me, but up to that time, all that I know of the article is its serial number, its professed character and the date on which I receive it. It is manifest that Mr. England's statements about the tendency of the system are wholly erroneous. While it may be believed by some persons that an analyst would, if he could, gratify a malignant spirit, it can hardly be believed, under the circumstances, that he could do so if he would.

As a matter of fact, the danger, if Mr. England's assumption were correct, would be rather in the direction of trying to save some one from a loss than of trying to cause one to occur. On the day of this writing, an intimate personal friend is condemned to a four hundred dollar loss, upon my certificate, because his importation contains 57% of adulterant, and it is a blessed relief that I am able to tell him that I knew nothing more of his sample than its date and number, until he himself informed me that it belonged to him.

Farther on, Mr. England asks, "Whoever heard of a Government official in any department, failing to sustain the scientific or technical report of a fellow official?" I think he will adopt a somewhat less cynical view upon my assurance that this is a common occurrence in the Bureau whose workings he is criticising. During

the month of January, I prevented two prosecutions by submitting a judgment that a fellow member was in error in his findings. I have in many cases rendered a favorable opinion of shipments that others had condemned, and vice versa. I have never known the slightest resentment or criticism to result from such action. My own judgments have been similarly disputed by others. Although in some such cases I have continued to believe my opinion to be the correct one, no thought of resentment has ever been excited. It is very likely that Mr. England's impressions on this subject have resulted from cases of the following kind. An importer who has always insisted upon his approval of the objects and purposes of the drug law, and who has given it his continued support, suddenly finds himself saddled with a shipment of the unfitness of which neither he nor any one else has any doubt. He may previously have condemned the importation of a shipment of far better quality, yet he now insists upon having his own importation released, and he resorts to every sort of misrepresentation of the case and to unjust criticism of the officer who condemned the goods, in his endeavor to escape the consequences of a mistake that he would have loudly condemned in any other. The rarest thing in all my experience, although I have known it to occur, is for an importer to exhibit a willingness to have the law justly enforced when this would result in a loss to him.

A far more serious question than any of the above is that of providing for judicial review of the findings of experts, which Mr. England strongly approves, and in which approval he is supported by many of the ablest lawyers, judges and legislators in the country. On general principles, it would seem clear that the importer should have this right and it is only the result of experience which can lead one to take the opposite view. Fortunately, we have an abundance of experience upon which to base our conclusions. All seizures of interstate shipments are subject to court review and many hundreds of such cases have been brought since the Federal Food and Drugs Act went into operation. At many of these trials, I have been a listener and I can recall scarcely any into which gross perjury did not enter. Were one to judge only by his observations of such cases, he would be likely to conclude that there is no other class of persons so dishonest as these expert witnesses. Leaving out of consideration all cases in which there is a fair ground of error and all differences of opinion, I do not hesitate to assert that in nearly all important cases one or more witnesses testify to what they know or fully believe at the time to be untrue. Our unfavorable opinion of these results must be qualified by the reflection that in most such cases, some experts have been asked to testify who have refused to do so, on conscientious grounds. Nevertheless, it is never difficult for an attorney to find one or more who are willing to thus degrade the profession. I have seen a chemist deny the pinkish-color which promptly appeared in the test performed in the courtroom while he was looking on. I have known a witness, after having sworn to an entirely different result from that which he had previously obtained, to retire under instructions of his attorney, so that he would not see the result of the same test applied in the presence of a jury and in this way would escape being compelled to state the truth concerning it. I have heard a witness testify that all volatile oils contain alcohol in varying amounts, oil of peppermint about 90%!

In this case, because that witness occupied the chair of *Materia Medica* in a medical college, while the one opposed to him was in a college of pharmacy, it was only with great difficulty that the jury could be convinced that his testimony was incorrect. It is this ignorance of the jurors, their complete dependence upon the statements submitted, and their unfitness for grasping and interpreting technical facts, in which the danger of this method of deciding such questions principally resides. As to the tendency of the witnesses to speak correctly, we must consider whether government witnesses, with no other influencing motive than that of justly and impartially upholding the law, are more or less likely to testify truthfully than are men who have been offered a rich fee, often a temptingly large one, to say that for the saying of which they are to be paid.

After all, could there be a more satisfactory method of deciding contested cases than by a central reviewing board at Washington, properly constituted and manned? Such a board should of course be sufficiently large to contain experts in every subject coming before it, so that it would collectively represent a greater and more accurate knowledge and better judgment than that of any of those whose opinions are to be reviewed. I am not discussing whether this is or is not true at present, but merely submitting the opinion that this method, properly carried out, is the ideal one and that it is free from those objectionable features which are collectively represented by the term "bureaucratic."

---

#### HYPODERMIC INJECTION OF PHENOL FOR TETANUS.

In spite of treatment by antitetanic serum, cases occur in which the course of the disease does not appear to be checked. In one such case of traumatic tetanus recorded, in which the gravest symptoms developed even after the administration of two successive injections of serum, rapid amelioration and ultimate cure were obtained by the use of hypodermic injections of phenol. The dose given was 2 mils of a 5 per cent. solution, every two hours for six days, then every four hours for another five days, after which they were no longer needed. No urinary pigmentation and no albuminuria were observed, but a carbolic rash appeared about the seventh day of treatment. It is stated that the gross mortality in cases treated with antitetanic serum is from 61.8 to 78.9 per cent. Bacelli, the originator of the phenol treatment, gives the mortality by that method as only 17.4 per cent. Since the hypodermic injection of phenol in no way interferes with the action of serum previously administered as a preventive, it is worthy of extended use where the former appears to have failed and the disease shows signs of developing.—Drs. Purves Stewart and J. T. C. Laing (*B. M. J.*, 1914, 2, 1098).

## Of General Interest

### IMPORTANT ANNOUNCEMENT.

At a joint meeting held on January 27, of the California Pharmaceutical Association, the Retail Druggists' Association of San Francisco, and the local branch of the American Pharmaceutical Association, a large attendance gathered at the Hofbrau Cafe for luncheon. The object of the meeting, as explained by President Green of the C. Ph. A., was to get the different associations and committees working harmoniously for the entertainment of druggists as guests during 1915.

On account of the A. Ph. A. making its time of meeting August 9 to 14, inclusive, it was decided, after considerable discussion, to have the state meeting the preceding Friday and Saturday, August 6 and 7.

The Chair appointed the following committees:—

*Committee on Entertainment.* All the C. Ph. A. Committee, and four additional names from the Retail Druggists' Association of San Francisco, to be appointed by its President, and two from the local branch of the A. Ph. A. to be appointed by Dr. Schneider.

*Committee on Permanent Headquarters.* I. Beck, L. A. Farran and E. R. McDonald.

*Committee on Finances.* E. A. Baer, W. Guerich and J. M. Casselman.

President Gerdes of the Retail Druggists' Association spoke of the desire and willingness of the San Francisco druggists to work with the State Association, and make this meeting a memorable one. Mr. Guerich followed with an outline of the progress made by them, and suggested that the committee on permanent headquarters look into the matter of securing exhibits from manufacturers. Secretary Bowerman of the C. Ph. A. was instructed to confer with the Secretary of the Retail Druggists' Association and the Secretary of the local branch of the A. Ph. A. and arrange for a large get-together meeting in the early part of March—preferably at the Palace Hotel. Secretary Bowerman was also instructed to have the American Druggists' Syndicate and the Rexall Company arrange the time for their annual conventions to coincide with the afore-

said August datings if possible. Also to arrange with Mr. Barr, Director of Congresses for the Panama-Pacific International Exposition for a suitable hall and to give an invitation to the druggists of Alameda county to meet with us and give us the benefit of their counsel and support.

K. B. BOWERMAN.

### NECROLOGY.

The members of the Association will learn with deep regret and sympathy of the demise of Mrs. Henry P. Hynson which occurred at Roland Park, a suburb of Baltimore on December 14, last. Mrs. Hynson was an invalid for several years, but through her long illness she maintained a cheerful disposition and her passing-away leaves a void not easily filled. The Journal extends to our esteemed fellow-member and the family its most sincere sympathy in the deep loss they have sustained.

## Proceedings of the Local Branches

### BALTIMORE.

The annual meeting of the Branch was held Wednesday evening, January 20, in the Hynson and Westcott assembly room at Charles and Franklin streets with President E. F. Kelly in the chair.

In the absence of the Secretary, E. W. Hodson, Wm. J. Lowry, Jr., Acting Secretary, served in his stead.

Mr. Louis J. Burger, a Ph. G., but now a member of the Baltimore bar and a United States Commissioner as well as Professor of Pharmaceutical Jurisprudence in the Department of Pharmacy of the University of Maryland, delivered an address on the Harrison bill, prefacing his remarks by suggesting to Mr. Hynson that he give a brief historical sketch of the bill.

This brought out that the bill had its beginning as the result of the work of Hamilton Wright of Vermont, which culminated in the pigeon-holed Foster bill. This bill had some excellent features but it required so many onerous entries, records, reports.

etc. that it would have necessitated an endless amount of acumen and accuracy to obey its mandates and avoid its penalties.

This bill was not reported out of committee, but the desire for national legislation to prevent the increasing spread of the narcotic habit evil was so great, that the different interests involved finally got together, through the Drug Trade Conference, and the Harrison bill was the outcome.

Mr. Burger went through the law thoroughly and took up a section at a time, stopping to answer questions as he went along and when he had finished, led the discussion which followed.

Mr. S. L. Hilton, a member of the Washington Branch, who took quite an interest in the bill while on its way through Congress, reviewed it and laid particular stress on the necessity of every pharmacist registering promptly, following its requirements thoroughly, and keeping records accurately.

He brought with him a copy of the proposed regulations and although they have not been adopted officially, yet they are practically completed and tell what to do and how to do it, in order to comply with the law.

The bill was discussed from every angle and view-point and a rising vote of thanks was extended to Messrs. Burger and Hilton for their painstaking and thorough exposition.

The incoming president was authorized to appoint a committee of five on publicity with the idea in view of acquainting the public through the press as to the workings of the law and also to prepare them for some of the shocks which they might otherwise receive when some of their old favorites are refused them.

The following officers were elected for the 1915 term: President, E. W. Hodson; Vice President and Chairman of the Executive Committee, Chas. C. Neal; Secretary and Treasurer, Wm. J. Lowry, Jr.; Assistant Secretary, Olive B. Cole; Chairman Committee of Practical Pharmacy and Dispensing, Chas. E. Meyer; Representative in the Council, Henry P. Hynson. The rest of the committees to be appointed by the president.

At the request of Dr. Chas. Caspari, Jr., the sense of the Branch was taken on the proposed change from Cubic centimeters to Milliliters in the coming Pharmacopœia and

it was suggested, though by no means unanimously, that Milliliters should be used.

It was decided to change the meeting night to the third Wednesday of each month instead of Thursdays as heretofore.

WM. J. LOWRY, JR., Secretary.

## CINCINNATI.

The regular monthly meeting of the Cincinnati Branch, A. Ph. A., was held at Lloyd Library, December 12, 1914.

President E. H. Thiesing presided.

The minutes of the previous meeting were approved.

The President announced the death of Mr. Matthew M. Yorston, a life member of the A. Ph. A., which occurred December 18. Prof. J. U. Lloyd spoke very feelingly of the early struggles of Mr. Yorston in the field of Pharmacy.

M. M. Yorston conducted a drug store in this city for years and was popularly known, as the man who introduced base ball into Cincinnati, he being the founder of the first Red Stocking Club in this city.

He came to this country from Glasgow, Scotland in 1851. From New Orleans he went to Louisville and entered the drug business. In 1859 he came to Cincinnati and opened a store. Mr. Yorston ranked high in the profession and on numerous occasions was a contributor to journals devoted to pharmacy.

The President appointed Messrs. Jones, Heineman and Apmeyer to act as a committee to frame a suitable resolution of condolence on the death of Mr. M. M. Yorston.

The report of the Committee on Memorial of Mr. Geo. Merrell was presented by Prof. J. U. Lloyd and a copy was ordered sent to the family and spread upon the minutes of the Association—Mr. Chas. G. Merrell, who was present, responded feelingly.

Mr. C. G. Merrell, as Chairman of the Committee on Program, announced several interesting features for the coming meetings.

Mr. H. W. Jones, Chairman on Progress of Pharmacy, made a very exhaustive and interesting report treating of the effects of the European war upon the drug business of America; the cultivation of Golden Seal; the efforts to restrict the sale of Bi-chloride tablets; the new British Pharmacopœia; Insecticides and Fungicides, and many other

matters of vital importance. At the conclusion of his address he received a vote of thanks.

Prof. Julius Greyer read a paper on "Mineral Waters," which was full of interesting and instructive information to all the members. The paper evoked an interesting discussion which was participated in by Messrs. Lloyd, Fennel, Merrell, Freericks and the author of the paper.

The Branch recommended this paper for publication in this Journal.

CHAS. A. APMEYER, Secretary.

<>

### CHICAGO.

The January meeting was held at the University of Illinois, School of Pharmacy Building, Friday evening, January 22.

In the absence of President Wells, Vice-President Day presided.

Secretary Gathercoal read a short report covering the year 1914 and stated that the Branch had held nine meetings during the year at each of which a profitable and interesting discussion of some subject pertaining to pharmacy had been held. He spoke of the wide publicity given the reports of the Branch meetings in the pharmaceutical press and expressed to its members the appreciation of the Branch. The financial report showed expenditures during the year of about \$70.00 and a balance on hand of \$28.90.

The following were elected to serve the Branch for the ensuing year:

President, Hugh Craig; First Vice-President, W. B. Day; Second Vice-President, C. A. Storer; Third Vice-President, Miss Jean Gordon; Secretary-Treasurer, E. N. Gathercoal; Chairman, Membership, L. L. Mrazek; Committee on Legislation, Jas. H. Wells; Committee on Practice, Wm. Gray; Committee on Medical Relations, Dr. Bernard Fantus; Committee on Publicity, Thos. Potts.

President Craig, introduced by Chairman Day, addressed the meeting on the very important subject: "The Administration of the Stamp Tax." Mr. Craig as editor of the Journal of the National Association of Retail Druggists, has personally requested of the Commissioner of Internal Revenue, rulings as to the stamp requirements on a number of articles commonly sold by druggists. The presentation and discussion of these rulings resulted in much practical information to the retail druggists present. In

Mr. Craig's opinion the pharmaceutical organizations should unite in opposition to any further extension of this emergency law beyond its present limitation, i. e., the end of this year. He stated that the prospects for a continued improvement in business conditions were certainly good and that with such improvement any necessity for an extension of the stamp tax beyond the present year should disappear. However, pharmacists, through their organizations, should present a strong protest against any possible extension of the law.

Dr. James H. Beal followed Mr. Craig with an address on the Harrison Act. As a delegate to the Drug Trade Conference, Dr. Beal has acquired a very intimate knowledge of this law, in fact, framing some of the provisions himself.

In his introduction, Dr. Beal explained why, ostensibly, this act was a Revenue Measure, but that in real intent it aimed to exercise such a control over the handling of the narcotic drugs, opium and coca leaves, as to destroy the drug habit evil. He stated that the law as it now stands was a compromise not fully meeting the ideas of either the Government or the Drug Trade Conference.

The various phases of the law were presented as answers to a series of questions: the first question being: "Who shall or shall not be licensed under this law?" The answer brought out the fact that any person whether physician, pharmacist, dentist, veterinarian or not, upon the payment of the license fee of \$1.00, might avail himself of the privileges of handling these narcotic drugs, while, of course, all who did deal in them must be so licensed. The real value of this portion of the law is in the publicity feature, for provision is made so that anyone may obtain a list of all such licensed persons and proper state and municipal officers may obtain copies of the quarterly reports that are required from all licensed persons, with such information, state and municipal anti-narcotic law violations may be rigidly prosecuted.

In his discussion of further questions, Dr. Beal made a number of prognostications as to the rulings of the Internal Revenue Department in reference to a number of interesting features. Thus he believes the Department will rule that licensed physicians may administer the prohibited drugs to the

patient at the bedside or in the home without keeping record of same but that when given to the patient in the office the proper records must be kept. Probably, as a protection to pharmacists, licensed physicians will be required to place on prescriptions calling for the prohibited drugs, the license number.

Dr. Beal was very sure that copies of such prescriptions could not be given and that such prescriptions could not be refilled and further that probably the refilling of prescriptions containing the prohibited drugs in excess of the excepted quantities and dispensed previously to March 1 next, would not be permitted.

One of the very onerous features of the original bill which required licensed persons to keep a balanced account of the sales of these prohibited drugs against their purchases was very fortunately replaced by the official order blank method. Now the pharmacist is required to keep on file for two years all orders for purchases, and all orders for sales and all prescriptions coming under this law and to report upon the same upon request of a revenue official.

Dr. Beal's address was most enthusiastically received and he was given a hearty vote of thanks.

About eighty pharmacists were in attendance.

E. N. GATHERCOAL, Secretary.

#### NEW ENGLAND.

A meeting was held on January 13 in Boston in conjunction with another local pharmaceutical association.

Fifty-five men partook of the fine dinner provided after which several topics of more than usual interest to the drug world engaged their attention.

The new narcotic laws, state and national, were the advertised topics for discussion and because of the intimate knowledge of these measures on the part of two ex-presidents of the Branch, Charles F. Nixon and James F. Finneran, most of the members went home with a feeling of having learned a great deal.

Charles A. Stover explained the working of a druggists' wholesale company which was launched in Boston some time ago and which may become a considerable factor in

the retail drug line as it has already proven profitable for those who are actively interested in it.

There were no formal papers presented at the meeting.

R. ALBRO NEWTON, Secretary.

#### NEW YORK.

The regular meeting of the New York Branch was held at the New York College of Pharmacy, President Army in chair, December 14, 1914. In the absence of Secretary McCartney, the chair appointed Jeannot Hostmann as secretary *pro tempore*.

The minutes of the previous meeting were approved.

The Chairman of the Committee on Legislation, Dr. Anderson, made a detailed and lengthy report on the status of anti-narcotic and stamp legislation and several rulings and decisions that had been given.

The report was discussed by Messrs. Bigelow, Diekmann and Diner.

Dr. Diekmann made a report on Pharmaceutical Progress which was discussed by Dr. Diner and Dr. Raubenheimer.

Chairman Bigelow, of the Mayo Dinner Committee, in reporting progress, announced that the dinner to President Mayo of the parent association would be held at the Chemist's Club on the evening of January 14, 1915 at 7:00 p. m.

Charles N. Lehman was elected a member.

Chairman Army appointed Messrs. Bigelow, Rehfuess and Diner as a Committee on Nominations.

Dr. Wimmer then read his very interesting paper on "Emulsions as Colloidal Systems" which was copiously illustrated. The paper was discussed by Messrs. Diner, Niece, Raubenheimer, Mayer, Turner and Roemer.

After tendering a rising vote of thanks to Dr. Wimmer the meeting adjourned.

JEANNOT HOSTMANN, Secretary *pro tem*.

The following officers were elected at the regular meeting of the New York Branch held on January 11, 1915 at the New York College of Pharmacy Building:

President, John Roemer; Vice-President, J. Leon Lascoff; Treasurer, Joseph Weinstein; Secretary, Jeannot Hostmann; Member of the Council, Thos. DeA. McElhenie; Chairmen of Committees: Education and Legislation, Wm. C. Anderson; Progress on

Pharmacy, George C. Diekman; Membership, J. H. Rehfuess; Fraternal Relations, Louis Berger.

At this meeting papers were read by Dr. Wm. Jay Schieffelin and Dr. H. H. Rusby. Dr. Schieffelin's paper was on "Dosage of Radium Emanations." [Published in the "Journal" of December.]

JEANNOT HOSTMANN, Secretary.

### PHILADELPHIA.

The regular meeting of the Philadelphia Branch was held Tuesday evening, January 12 at the Medico-Chirurgical College.

President E. Fullerton Cook called the meeting to order at 8:15 p. m. The minutes of the last meeting were read and approved.

A communication from the chief of the Bureau of Chemistry of the Department of Agriculture, in answer to a resolution passed at the November meeting, concerning the definition of the word "dram" as expressed in General Information Opinion No. 66 issued July, 1914, was read. The full text of the letter is as follows:

December 16, 1914.

Mr. J. Ed. Brewer, Secretary, Philadelphia Branch, American Pharmaceutical Association, 1705 Cherry Street, Philadelphia, Pa.:

Dear Sir: Your letter of November 16, embodying a resolution adopted by your local branch relative to the use of the word "dram" has been received.

In construing the Net Weight Amendment upon which Opinion 66 was based, inasmuch as this has to do with articles of food, it was necessary to adopt the avoirdupois system. The dram is a unit of the avoirdupois system and also of the apothecary system, but its use under the apothecary system does not occur in the application of the Net Weight Amendment to foods. It is, of course, applicable in case of small quantities of drugs or other commodities sold in the pharmaceutical trade. In the apothecary system the word "dram" is used as a unit of weight and where used as a unit of measure, as it often is, it would appear that it should be designated as a fluid dram. A similar duplication appears in the use of the word "ounce" in liquid measure, and it has seemed desirable to this Bureau that where the term "ounce" occurred in liquid measure it should be designated as a fluid ounce reserving to the word "ounce" its designation as a term of the avoirdupois system.

So far as a practical application of the use of the word "dram," either under the avoirdupois system or apothecary system, or the

term "fluid dram," is concerned, it would appear to be of minor importance as it denotes a unit which is below that which is expressed under paragraph (e) of Food Inspection Decision 154, copy of which is enclosed.

Trusting this will explain the position of this Bureau and that it will not be in conflict with the proper use of the term "dram" in the pharmaceutical trade,

Respectfully,

(Signed) C. L. ALSBERG,  
Chief.

It was moved and passed that the letter be accepted and placed on file.

Under the heading of deferred business Prof. C. H. LaWall read the report of the committee appointed at the December meeting to draw up an answer to the letter from Pearson Publishing Co. concerning the article Pills and Piracy which appeared in the November issue of Pearson's Magazine.

Prof. F. E. Stewart moved that the report be submitted to the Council of the American Pharmaceutical Association with the request that they forward it to the Pearson Publishing Co. for publication. The motion carried.

The program of the evening was then taken up and Mr. Louis K. Liggett delivered an address on "Modern Drug Store Merchandising."

"The Current Review of Pharmaceutical Journals" was presented by Mr. John K. Thum.

As moved by Prof. F. E. Stewart a standing vote of thanks was given to Messrs. Liggett and Thum.

During the discussion of the papers Pharmacy from a professional aspect was interestingly presented by Mr. Franklin M. Apple, Prof. J. P. Remington and Prof. F. E. Stewart—after which the meeting adjourned.

J. ED. BREWER, Secretary.

### SAN FRANCISCO.

The San Francisco Branch met at 723 Pacific Building on the evening of January 12 to discuss "Qualifications to practice Pharmacy." The general opinion prevailed that any one intending to study pharmacy should have a definite and sufficient preliminary general education followed by systematic special instruction in a recognized pharmaceutical school. Further discussion

centered on the value of drug store experience and it was thought that only such experience should be valued as is obtained from actual practice in the performance of pharmaceutical work under the direction of experienced pharmacists. The mention of recognized pharmaceutical school also called for opinions on what constitutes a recognized school. In the discussion that followed, entrance requirements, faculty, general administration received due consideration.

Mr. J. L. Lengfeld spoke of Potassium Tellurite as an indicator of microbial life. Samples and literature were shown—these having been sent by the Research Department of Parke, Davis & Co.

Mr. William Milton Cordivenus applied for membership in the American Pharmaceutical Association and in the local branch. The S. F. Branch is pleased to add Mr. Cordivenus to its roll as he has always taken an active interest in pharmaceutical affairs.

The Branch adjourned to meet again on February 9, (second Tuesday), 723 Pacific Building. "Standardization of Pharmaceuticals" will be the topic for the evening.

CLARISSA M. ROEHR, Secretary.

#### SAINT LOUIS.

A regular meeting of the Saint Louis Branch was held in the St. Louis College of Pharmacy, January 15, 1915. The meeting was called to order by Dr. O. E. Claus. After the disposal of the routine business the chair called upon Mr. A. W. Pauley, who presented his paper "Commercial Pharmacy—A Timely Topic." The paper elicited much discussion.

The Secretary read the paper entitled "The Sale of Poisons," contributed by Mr. Mittelbach, Booneville, Mo.

Dr. H. M. Whelpley gave a brief summary of the Harrison law.

Mr. P. L. Gain of East St. Louis, Ill. spoke in behalf of the Illinois Pharmaceutical Association meeting to be held at Centralia, June 14-16.

JULIUS C. HOESTER, Secretary.

#### WASHINGTON, D. C.

The January meeting was held January 27, 1915, at the National College of Pharmacy. The subject presented for discussion was the new Imperial British Pharmacopœia, by M. I. Wilbert.

The subject was ably handled from the view-point of modern medicine and pharmacy as well as to its origin and history, most interesting data being given which clearly showed the chaotic condition of pharmacopœial standards in the British Empire previous to the issue of the British Pharmacopœia of 1914.

It was further pointed out that much dissatisfaction exists among the pharmacists owing to the fact that after the British Pharmaceutical Society had assisted and performed an enormous amount of work in connection with the revision, little if any credit has been given to the pharmacists.

The new British Pharmacopœia shows 43 additions and 160 deletions. It contains many of the newer remedies that will not be included in the coming revision of the U. S. Pharmacopœia, while such drugs as figs, prunes, sarsaparilla, sassafras, Co. Spirit of Ether and brandy have been deleted. It contains but 17 fluidextracts and 16 tinctures, plasters have almost lost their place among the official recognized medicaments, infusions and decoctions are however still popular.

The decided innovation in this revision of the British Pharmacopœia is the dropping of the Imperial system of weights and measures and the adoption of the metric system. The sanctioning of the term *Mil* instead of Cubic Centimeter is in accord with modern scientific trend. Doses are given in both metric and Imperial systems. Here the same error has been made that was made in the U. S. P. VIII, accuracy being sacrificed as to the proper equivalents.

Official abbreviations are recognized in the appendix, which also contains many general processes for both chemical and other substances, including elaborate descriptions even histological characteristics, and most rigid requirements as to freedom from traces of arsenic and lead. Many assays for crude drugs and galenicals are given as well as for volatile oils.

It remains to be seen whether the publication will be a pharmacopœia for the entire

British Empire, as designed, as it has already been severely criticized and many of the provinces are very much dissatisfied with the revision.

Owing to the peculiar features of the copyright laws of Great Britain the British Pharmacopœia becomes official before publication, it is, however, placed on exhibition for a period previous to becoming official.

The paper brought out much discussion that was participated in by all present.

S. L. HILTON, Secretary.

#### WEST VIRGINIA.

This, the youngest Branch of the A. Ph. A. organized at Morgantown, November 19, 1914. The following officers were elected:

President, W. A. Ream; Vice Presidents, G. O. Young, John Coleman, C. A. Neptune; Secretary, A. B. Berry; Treasurer, W. C. Price; Council Representative, Prof. Charles H. Rogers.

Prof. Rogers read an address from Secretary England entitled, "Dreaming and Doing." [Published in December issue.]

A vote of thanks was tendered Mr. England for his delightful address.

A resolution was adopted favoring the passage of a bill by the W. Va. Legislature creating the offices of state food and drug inspectors and the secretary was instructed to communicate with Governor Hatfield concerning the matter.

There was a good attendance at this, our first meeting and the prospects are bright for a vigorous, active branch.

The results thus far obtained are largely due to the push and energy of Prof. Rogers of the Department of Pharmacy of the West Virginia University.

The January meeting occurred on Wednesday evening, January 20, at Woodburn Hall, of the University of West Virginia.

After the dispatch of the regular business the members had the pleasure of listening to two very interesting and instructive addresses—one by Dr. A. Arken of the College of Medicine, W. Va. University, and the other by Prof. Chas. H. Rogers of the College of Pharmacy, W. Va.

Dr. Arken's subject was "Serums and Vaccines" and he told of their origin and modes of preparation and the successes attained by their use in the treatment of disease.

Dr. Arken is thoroughly acquainted with

this subject and is a logical and forceful speaker.

Prof. Rogers spoke entertainingly on "Organic Chemistry."

Our membership embraces members from all parts of the state and there is no question of the success of the Branch and that it will have considerable influence in aid of the advance of Pharmacy in the state.

A. B. BERRY, Secretary.

### Council Business

#### COUNCIL LETTER No. 14.

Philadelphia, Pa., January 15, 1915.

To the Members of the Council:

The following tentative program for the sixty-third annual meeting of the Association, to be held at San Francisco during the week of August 9 to 14, 1915, is submitted by the Committee on Program, the General Secretary, Secretary of the Council and Local Secretary:—

#### Monday:

- 9.00 A. M. Meeting of the Council.
- 3.00 P. M. First General Session.
- Meeting of Committee on Nominations.
- Meeting of Committee on Resolutions.
- 7.30 P. M. House of Delegates.
- 9.30 P. M. President's Reception.

#### Tuesday:

- 9.30 A. M. Second General Session.
- 10.00 A. M. National Association of Boards of Pharmacy.
- 2.00 P. M. Scientific Section.
- Women's Section.
- Commercial Section.
- National Association of Boards of Pharmacy.
- 7.30 P. M. Meeting of the Council.
- House of Delegates.
- Ladies' Theatre Party.

#### Wednesday:

- 9.30 A. M. Section on Education and Legislation.
- Commercial Section.
- 12.30 P. M. Luncheon of College Alumni.
- Luncheon to A. C. P. F. by California College of Pharmacy.
- 2.00 P. M. Scientific Section.
- Section on Practical Pharmacy and Dispensing (and Pharmacopœias, Formularies, and Standards.)
- National Association of Boards of Pharmacy.
- American Conference of Pharmaceutical Faculties.

- 7.30 P. M. Meeting of Council.  
National Association of Boards  
of Pharmacy.  
American Conference of Phar-  
maceutical Faculties.  
Ladies' Reception.

Thursday:

- 9.30 A. M. Section on Education and  
Legislation.  
Scientific Section.  
Practical Pharmacy and Dis-  
pensing (and Pharmacop-  
oeias, Formularies and  
Standards.)  
2.00 P. M. Joint Session of Section on  
Education and Legislation,  
the A. C. P. F. and N. A. B.  
P.  
Historical Pharmacy.  
Women's Section.  
7.30 P. M. Meeting of the Council (Re-  
organization.)  
8.00 P. M. House of Delegates.  
Ladies' Reception.  
Visit to Chinatown.

Friday:

- 9.00 A. M. Meeting of the Council.  
10.30 A. M. Final General Session.  
1.30 P. M. Luncheon and Adjourned  
Final General Session at the  
Inside Inn, Exposition  
Grounds.  
3.00 P. M. Go-as-you-please Exposition  
Visit.  
6.00 P. M. Luncheon at the Inside Inn,  
Exposition Grounds.  
7.30 P. M. Exposition Visit Continued—  
The Concessions and Illumi-  
nations.

Saturday:

The Local Committee suggests that Satur-  
day be given up to local visits and ex-  
cursions, arranging the parties to suit. Some  
may desire to visit Mt. Tamalpais, others the  
Exposition and still others may desire to go  
to the Muir Woods, the University in Berke-  
ley, Golden Gate Park.

Comments and suggestions are invited by  
the Committee on Program.

The Philadelphia Branch, through a  
special committee, has drafted a reply to an  
article that recently appeared in Pearson's  
Magazine, claiming that pharmacists charged  
the public a higher price for drugs bought  
on prescription than for the same drugs  
bought in bulk. It is the wish of the local  
branch that the reply be passed upon by the  
Council before it is sent to Pearson's Maga-  
zine for publication, in response to their of-  
fer of space for the presentation of the  
pharmacists' side of the question.

The statement is as follows:

The undersigned members of a committee  
appointed by the Philadelphia Branch, A. Ph.  
A., to draft a reply to the article entitled,

"Pills and Piracy" published in Pearson's  
Magazine for November, 1914, hereby pre-  
sent a report in the shape of a dignified im-  
partial statement of the facts justifying the  
fees charged by Pharmacists for professional  
services in the compounding of prescriptions.

Respectfully submitted

CHARLES H. LAWALL, Chairman,  
FRANKLIN M. APPLE,  
CHAS. LEEDOM.

*Are Pharmacists' Fees Fair?*

"Each in his place, by right, not grace,  
Shall rule his heritage—  
The men who simply do the work,  
For which they draw the wage."

The profession of pharmacy is one of  
antiquity and honor. In its beginning it was  
intimately associated with the practice of  
medicine. Later on it was closely connected  
with alchemy, out of which grew our won-  
derful modern science of chemistry. Phar-  
macy was evolved as a separate profession  
through necessities which are clearly ap-  
parent to a student of the subject. The  
physicians of early times soon found that  
the practice of their own profession was a  
difficult enough undertaking alone. They,  
therefore, assigned to the pharmacist, then  
usually called the apothecary, the necessity  
and duty of posting himself upon the knowl-  
edge connected with the preparation of  
medicines for administration, the physician  
reserving for himself the right to diagnose  
the disease and prescribe the remedy.

The pharmacist-chemist soon found that  
the increased responsibilities placed upon  
him by the physician prevented him from de-  
voting much time to researches in chem-  
istry. In this way has come about the evo-  
lution of professional pharmacy of to-day.  
There are different kinds of pharmacists to-  
day, just as there are different kinds of phy-  
sicians, magazine writers and legislators.  
The pharmacist of to-day stands between  
the physician and the public for the purpose  
of serving both; both need this service, and  
to serve both properly means to be specially  
educated for the purpose.

A pharmaceutical education of to-day  
takes little less time and money than a medi-  
cal education and compares closely in these  
respects with the professional education of  
doctors of dental surgery and of doctors of  
veterinary medicine. The time required and  
the money expended for this education  
makes it necessary for the pharmacist to

charge a fee for his professional services in filling prescriptions.

Nobody who appreciates the responsible character of the service thus rendered by the conscientious pharmacist ever criticises him for this. Every day he has the dispensing of life or death in the hollow of his hand; every day he takes upon himself the responsibility for the success or failure of the treatment of the case by the physician, assuming, of course, that the treatment is correct in principle. For this conscientious service he has the satisfaction of knowing that he has done his duty, for the profits of the prescription department in the majority of drug stores are a minus quantity. The pharmacist, besides being a professional man, must needs also be a business man or he could not make a living. If the sale of medicines and the compounding of prescriptions only were permitted by pharmacists, many communities would be without a pharmacy, for our progress along lines of preventive medicine has largely reduced the use of medicines by the educated physicians of to-day.

It is not denied nor is it necessary to apologize for the fact that a higher charge is often made for substances dispensed upon prescriptions than when these substances are sold over the counter in the uncompounded condition. Take as a concrete example the hypothetical case of a prescription for sodium bicarbonate or baking soda, to be divided into ten or twelve equal doses, as contrasted with an order for ten cents' worth of baking soda. The order for ten cents' worth of baking soda can be filled by anybody who happens to be back of the counter; even the errand boy or the soda water clerk has sufficient intelligence to go to the compartment where ready prepared packages (previously put up and labeled) are kept, hand it over the counter and take the money, but when a prescription for the same substance is brought in it is a totally different matter. Under all existing pharmacy laws the filling of prescriptions can only be legally done by a registered pharmacist, who is the highest salaried clerk in the store; the entire transaction is handled by him, including the filling of the prescription, the labeling and wrapping of the package. This, with the accurate subdivision into a number of doses,

takes the time of this educated, high salaried clerk. There is no more justification for censure of the pharmacist, who under these conditions makes a greater charge for the same substance than was made in the other transaction, than there is for the censure of the physician who writes such a prescription making necessary this expensive service, instead of simply telling the patient, as he might have done, to go to the drug store and get ten cents' worth of sodium bicarbonate and take a certain amount ever so often. The physician, on his part, has had to go through a long and expensive course of education to be able to tell that bicarbonate of sodium was the substance best suited to the patient's needs, and is therefore entitled to a fee for this knowledge.

This larger charge upon articles supplied upon prescriptions is not an invariable rule or practice. The public has come to expect and the practice of pharmacists for several generations has been to price prescriptions upon a flat rate according to the size of the container or the dosage represented. With the advent of many expensive remedies has come many instances where no profit is made or even a slight loss sustained in order to maintain this uniformity of procedure. Also, if existing conditions showed that pharmacists were amassing large fortunes or that they were even better off, upon the average, than members of other professional callings requiring equal educational attainments, there would be grounds for criticism, but when it is realized that all the laws upon the statute books affecting pharmacy, requiring, as they do, preliminary education, and in several states graduation from a pharmacy college of approved standing before examination for registration, it seems like carping criticism to find fault with the pharmacist on account of prescription prices, and to allege dishonorable motives is to do a grave injustice to a profession which has as honorable record as any and in whose history can be found many names of those who have been the world's pioneer discoverers of valuable products and of those who have benefited the human race without hope of fee or reward.

"They that have wrought the end unthought  
Be neither saint nor sage,  
But men who merely did the work  
For which they drew the wage."

*Motion No. 26 (Reply to Article in Pearson's Magazine).* Do you approve of the above reply of the Philadelphia Branch and the sending of the same to Pearson's Magazine?

*Motion No. 27 (Application for Membership).* You are requested to vote on the following applications for membership:—

## The Pharmacist and the Law

### THE MULFORD PROTEST AGAINST INCREASE IN FREIGHT RATES.

The Western Traffic Association having withdrawn classification on drugs and chemicals in less than car-load shipments, the result of which action is an increase of 85% in freight-rates on such goods, the H. K. Mulford Company of Philadelphia has filed the following petition with the Interstate Commerce Commission:—

#### THE INTERSTATE COMMERCE COMMISSION.

H. K. Mulford Company against Pennsylvania Railroad Company, Pennsylvania Company, Chicago, Milwaukee & St. Paul Railway Company, Baltimore & Ohio Railroad Company, Chicago, Burlington & Quincy Railroad Company, and Northern Pacific Railway Company.

#### PETITION.

The petition of the above-named petitioner respectfully represents:

#### I.

That your petitioner is a corporation duly incorporated under the laws of the State of Pennsylvania, and its business is that of a manufacturing chemist, which it carries on in the city of Philadelphia, State of Pennsylvania.

#### II.

That the respondents are common carriers engaged in the transportation of passengers and property by continuous carriage or shipment, wholly by railroad, between points in different states of the United States, and particularly they are engaged in the carriage of drugs and chemicals from the city of Philadelphia, in the State of Pennsylvania, to points on the Pacific Coast, and are subject to the provisions of the Act to Regulate Commerce, approved February 4, 1887, and acts amendatory thereof or supplementary thereto.

#### III.

That under tariffs filed with your body on October 1, 1914, and which went into effect on November 15, 1914, the respondents, the Pennsylvania Railroad Company, the Pennsylvania Company and the Chicago, Milwaukee & St. Paul Railway Company, have

joined in a joint rate for the carriage of drugs and chemicals in less than carload lots over a through route from the city of Philadelphia, in the State of Pennsylvania, to points on the Pacific Coast, of \$3.70 per hundred pounds, and the respondents, the Baltimore & Ohio Railroad Company, the Chicago, Burlington & Quincy Railroad Company and the Northern Pacific Railway Company, have joined in a similar joint rate.

#### IV.

That the said charge is an increase of 85% on the charge imposed prior to the effective date of the above-mentioned tariff and is unjust and unreasonable.

#### V.

That your petitioners, as shippers of drugs and chemicals from the city of Philadelphia to points on the Pacific Coast have, by reason of the facts stated in the foregoing paragraph, been subjected to the payment of rates of transportation which were, when enacted, and still are, unjust and unreasonable and are in violation of Section 1 of the Act to Regulate Commerce.

WHEREFORE your petitioner prays that the respondents may be severally required to answer the charges herein; that after due hearing and investigation an order be made commanding said respondents and each of them to cease and desist from the aforesaid violation of said Act to Regulate Commerce, and establish and put in force and apply as maximum rates in future to the transportation of drugs and chemicals in less than carload lots between the shipping and destination points named in Paragraph III hereof, in lieu of the rates named in said paragraph, such other rates as the Commission may deem reasonable and just, and also pay to your petitioner by way of reparation for the unlawful charges hereinbefore described such sums as, in view of the evidence to be adduced herein, the Commission may consider your petitioner entitled to, and that such other and further order or orders be made as the Commission may consider proper in the premises and petitioner's cause may appear to require.

Dated at Philadelphia, Pa., January 15, 1915.

H. K. MULFORD COMPANY.

Address: 412 to 432 South Thirteenth Street, Philadelphia, Pa.

#### HARRISON ANTI-NARCOTIC LAW.

The National Wholesale Druggists' Association has issued a circular letter to its members from which we excerpt the following information regarding the requirements of this law.

#### PRINCIPAL FEATURES OF THE HARRISON BILL.

The law covers opium, coca leaves, and any compound, manufacture, salt, derivative or preparation thereof.

Every person, firm or corporation, who produces, imports, manufactures, compounds, deals in, sells, distributes or gives away any of the articles covered by the law, must register with the collector of Internal Revenue in his District and pay a special tax of \$1 per year. The special tax will be imposed for the period from March 1 to June 30, 1915 (which is the close of the special tax year), and the amount to be paid is 34 cents. After that date, tax will be imposed for the official year and payment will be \$1.

Employees, while acting within the scope of employment by the taxpayers, will not be required to register or pay the special tax. Every person, partnership, association, company or corporation (other than a physician, dentist or veterinarian), who has more than one place of business where any of the drugs described are made, stored, or dispensed, must make a separate application for registry and pay special tax for each such place of business.

Sales of the drugs covered by the law may be made only to parties, whether manufacturer, wholesaler, retailer or doctor, on order-blanks provided by the collector of Internal Revenue. The buyer and the seller shall each preserve his copy of the order, and the law requires all such orders (both original and duplicate) to be retained on file for a period of two years, and they must be filed in their numerical order; that is, according to the registry numbers. Dealers are not compelled to fill orders for narcotic drugs, as the law provides what he shall do in case the order is accepted.

It is unlawful for any person to obtain by means of said order-blanks any of the aforesaid drugs for any purpose other than the use, sale or distribution thereof by him in the conduct of a lawful business in said drugs or in the practice of his profession. Orders by telegraph or telephone cannot be filled.

Order-blanks will be issued by collectors of Internal Revenue in tablets or books of ten or fifty blanks each. The charge for such blanks (including original and duplicate) will be at the rate of \$1 per hundred. They will be issued only to persons who have registered and paid the tax, and any one other than the dealer to whom they are issued using them will violate the law.

Dealers may not sell to physicians on prescription when the drugs are intended for dispensing or prescribing, as all physicians, dentists and veterinarians, will be required to register under the law and order such drugs on the official order-blanks. Prescriptions written by physicians and filled either by the druggist or physician, must bear the name of the physician signing the same, and his registry number, and the name of the person for whom such prescription is filled. Such prescriptions must be preserved for a period of two years, and be readily accessible to the inspecting officers of the Government, State, District or City in which he is located.

Every person, firm or company *dispensing directly to consumers*, must on March 1, 1915, prepare and keep on file an inventory of all drugs covered by the law on hand at that date; no special form of inventory is required, and it must be verified by oath not later than March 5, 1915.

Every person registered under the act is required on demand of the collector of his district to render a sworn statement of the quantity of such drugs received by him during a period not exceeding three months preceding such demand. The said statement to show the names of the persons from whom the said drugs were received, the quantity received, and the date thereof. This record can be readily compiled from the duplicate orders on file.

It is a crime under the act for any person who is not registered and has not paid the tax to have in his possession or under his control any of the aforesaid drugs, and such possession will be construed as presumptive evidence of a violation of the act. This provision, however, does not apply to any employees of a registered person or to a nurse under the supervision of a physician, dentist or veterinary surgeon registered under the act, provided such possession is by virtue of his employment or occupation, and not on his own account.

United States, State, county, municipal, territorial and insular officers lawfully engaged in making purchases respectively for the army and navy, the Public Health Service, and Federal, State, county and municipal, territorial, and insular hospitals or prisons, are exempted from the provisions of the law; and sales, deliveries, etc., to these officers and institutions are not affected by the law, but private hospitals and institutions are not exempted.

Section 6 of the law exempts from its provisions all preparations and remedies containing stipulated quantities of the prohibited drugs, but it should be carefully noted that these exemptions do not apply to cocaine or any of its salts, whether alone or in combination with other drugs, and all sales of cocaine in any or every form whatever must be made in pursuance of a written order on the blanks supplied by the collector. It will

also be noted that while the title of the law and the first section of it does not mention alpha or beta eucaine, Section 6 provides that the exemptions shall not apply to "liniments, ointments and *other preparations* which contain cocaine or any of its salts or alpha or beta eucaine or any of their salts or any synthetic substitute for them."

It should be remembered that the Harrison law is a taxation or revenue measure and applies to all transactions in every State, city or town, and is not confined to sales in interstate traffic. It should also be borne in mind that it is necessary for all dealers to continue to observe State and municipal laws regarding the sale of narcotic and poisonous drugs. Attention is also called to the fact that there is no advantage in retailers or dispensers purchasing large quantities of the prohibited drugs prior to March 1, as it will only add to the work of reporting stocks on hand in the inventory required by the regulations to be taken on that date.

The penalty for violating any of the provisions of the law is a fine of not more than \$2,000 or imprisonment for not more than five years, or both, as well as the probable large expense incurred when suit is brought.

#### LISTS OF ARTICLES COMING UNDER THE PROVISIONS OF THE LAW.

Following find lists of drug products affected by the law. We have endeavored to secure as complete lists as possible of drugs, pharmaceutical preparations and proprietary medicines which must be sold only on presentation of the proper order-blanks. The lists are, of course, not complete or entirely accurate, but are sent out for the purpose of assisting persons registered under the act in segregating the articles coming under the operation of the law. In view of the fact that the Food and Drugs Act of June 30, 1906, requires that any of the drugs mentioned in this law shall be shown on the label, dealers should be able to determine without much difficulty whether a particular item comes within the provisions of the law or not.

#### PHARMACEUTICALS.

List furnished by Eli Lilly & Co. It is submitted subject to changes, omissions and corrections:

*Fluid Extracts*—Coca, U. S. P.; Coca, Soluble; Kola, Compound; Opium, Camphorated; Opium, Concentrated; Poppy Heads; Saw Palmetto, Compound; White Pine Compound, for making Syrup; White Pine Compound, Red, for making Syrup; Wild Cherry, Compound.

*Pills*—Alterative; Ammonium Muriate, Compound; Anodyne; Antispasmodic; Blue Mass, Compound; Calomel and Opium; Camphor, Compound; Camphor, Opium and Hyosevamus; Camphor, Opium and Lead Acetate; Camphor, Opium and Tannin; Coca and Phosphorus, Compound; Coca, Phosphorus and Strychnine; Cocaine Hydrochloride (all sizes); Codeine (all sizes);

Codeine Sulphate (all sizes); Diaphoretic; Diarrhea Pellets; Heims; Heroin (all sizes); Ipecac and Opium (all sizes); Mercury Protiodide and Opium; Mercury and Chalk, No. 2; Morphotropia (all sizes); Morphine Sulphate (all sizes); Morphine Valerianate (all sizes); Neuralgic, Brown-Sequard; Neuralgic, Brown-Sequard, Half Strength; Neuralgic, Gross, N. F.; Neuralgic, Gross, Half Strength; Neuralgic, Gross, Pink Granules; Opium, Extract (all sizes); Opium, U. S. P.; Opium, Powdered (all sizes); Opium and Camphor, N. F.; Opium and Lead Acetate (all sizes); Opium and Silver Nitrate; Opium, Tannin and Lead; Phenacetine and Quinine, Compound; Quinine and Dover's Powder; Syphilitic, Ricord, Modified; Terpin Hydrate and Codeine.

*Hypodermatic Tablets*—Anti-asthmatic, Timmerman; Apomorphine Hydrochloride (all sizes); Apomorphine and Strychnine; Cocaine Hydrochloride (all sizes); Codeine Phosphate (all sizes); Codeine Phosphate without Sugar (all sizes); Codeine Sulphate (all sizes); Codeine Sulphate without Sugar (all sizes); Diacetylmorphine Hydrochloride, (all sizes); Eserine and Morphine; Eucaine Hydrochloride (all sizes); Eucaine Lactate; Heroin Hydrochloride (all sizes); Hyoscine, Compound, Lilly; Local Anesthetic, Dental (all sizes); Morphine Hydrochloride (all sizes); Morphine Meconate (all sizes); Morphine Nitrate (all sizes); Morphine Sulphate (all sizes); Morphine and Atropine (all sizes); Morphine, Atropine and Strychnine (all sizes); Morphine and Hyoscine; Morphine and Strychnine (all sizes); Morphine, Compound, Tupper; Nitroglycerin, Compound, Lilly; Novocain; Scopolamine and Morphine (all sizes.)

*Soluble Tablets for Local Anaesthesia*—All Strengths.

*Ophthalmic Tablets*—Cocaine Hydrochloride.

*Veterinary Hypodermatic Tablets*—Cocaine Hydrochloride (all sizes); Colic, Knowles; Morphine Sulphate (all sizes); Morphine and Atropine (all sizes.)

*Tablets*—Acetanilide, Compound No. 7; Acetanilide, Compound with Codeine No. 1; Acetanilide, Compound with Heroin; Acetanilide and Sodium, Compound with Codeine; Acetphenetidin, Compound with Codeine; Alum, Compound No. 1, for Injections; Alum, Compound No. 2; Ammonium Chloride, Compound with Codeine; Ammonium Chloride, Compound with Heroin; Ammonium Salicylate and Acetanilide Compound; Ammonium Salicylate and Acetanilide Compound, Half Strength; Anodyne, Expectorant, Bolton; Anodyne, Infant, Waugh; Anodyne, Lilly; Anodyne, Mild; Antiasthmatic, Stevens; Antibronchitis; Anticold; Anticold, Gordon; Antidiabetic; Antivomiting (Nos. 1 and 2); Apomorphine Hydrochloride (all sizes); Aspirin and Codeine; Aspirin, Compound, Kyle; Astringent

Wash; Atropine-Aconite, Compound; Bismuth and Opium; Bismuth, Opium and Carbolic Acid; Blue Mass, Compound; Boric Acid and Potassium, Compound; Bronchitis, Delafield; Brown Mixture (all sizes); Brown Mixture and Ammonium Chloride; Calomel and Dover's Powder (all sizes); Camphor, Opium and Tannin; Cardiac, Waldstein; Chlorodyne; Chlorodyne, Half Strength; Coca, Fluid Extract; Cocaine Hydrochloride (all sizes); Cocaine and Cubebs, Compound; Codeine (all sizes); Codeine without Sugar (all sizes); Codeine Phosphate (all sizes); Codeine Sulphate (all sizes); Codeine Sulphate without Sugar (all sizes); Cold No. 3; Cold No. 3 with Aloin; Cold No. 5; Cold No. 6; Cold, Laxative, Lilly; Cold, Preferred; Copper and Opium; Coryza, No. 1; Coryza, Bishop; Coryza, No. 2; Coryza, improved, Lilly; Coryza, Kenyon; Coryza, Smith; Cough No. 1; Cough No. 2; Cough, Infant; Creosote, Compound; Diabetes; Diacetylmorphine (all sizes); Diacetylmorphine Hydrochloride (all sizes); Diaphoretic, Whitford; Diarrhea No. 2; Diarrhea No. 3, Sullivan; Dover's Powder (all sizes); Enteritis, Haskell; Expectorant, Rankin; Expectorant, Tonic; Febrifuge; Fever; Fever, Kenyon; Follicular, Tonsillitis; Gastritis; Helonias, Compound, Vaginal; Heroin (all sizes); Heroin Hydrochloride (all sizes); Heroin and Terpin Hydrate (all sizes); Hydrastine, white Alkaloid, Compound; Lead and Laudanum; Leucorrhea Mercury with Chalk and Dover's Powder; Mercury Protiodide and Opium; Morphine Acetate (all sizes); Morphine Hydrochloride (all sizes); Morphine Sulphate (all sizes); Morphine and Atropine (all sizes); Morphine and Belladonna; Naso-Pharyngeal; Nausea No. 2; Neuralgic; Neuralgic, Brown-Sequard; Neuralgic, Brown-Sequard, Half Strength; Neuralgic, Dunlap; Neuralgic, Gross; Neuralgic, Gross, Half Strength; Neuralgic, Headache, Myers; Opium, Camphorated, Tincture (all sizes); Opium, Deodorized, Tincture; Opium, Powdered (all sizes); Opium, Tincture U. S. P. (all sizes); Opium and Camphor; Opium, Ipecac and Blue Mass; Opium and Lead Acetate (all sizes); Paregoric, Compound; Potassium Chlorate and Cocaine, Voice Tablet; Quinine and Dover's Powder; Rheumatism Liggett; Salicylic Acid and Morphine; Salol, Compound; Sun Cholera; Syphilitic; Terpin Hydrate and Codeine (all sizes); Terpin Hydrate, Compound, Brockbank; Terpin Hydrate and Heroin, Compound, Lilly; Throat, Mentholated, Lilly; Throat, Quinlan; Tully's Powder (all sizes); Uterine Astringent and Antiseptic; Voice.

*Dispensing Tablets*—Cocaine Hydrochloride (all sizes); Codeine (all sizes); Codeine Phosphate (all sizes); Codeine Sulphate (all sizes); Heroin Hydrochloride (all sizes); Morphine Hydrochloride; Morphine Sulphate (all sizes.)

*Compressed Lozenges*—Glycyrrhiza and Opium U. S. P.; Pectoral, Jackson; White

Pine, Compound Cough Lozenges; Wistar's Cough Lozenges.

*Elixirs*—Ammonium Valerianate and Morphine; Celery, Compound; Celery, Kola and Coca, Compound; Chloroform, Compound, N. F.; Coca; Coca, Compound; Creosote and Terpin Hydrate, Compound; Heroin; Heroin, Compound; Heroin and Terpin Hydrate; Kola, Compound; Morphine Hydrochloride; Opium, Deodorized; Pectoral, or Pulmonic, Elixir; Saw Palmetto, Compound; Saw Palmetto and Pichi, Compound.

*Syrups*—Codeine Phosphate, Compound; Dover's Powder; Heroin, Compound; Tolu, Compound; White Pine, Compound, with Heroin.

*Wines*—Coca, Aromatic; Coca, Beef and Iron; Coca and Celery; Coca with Hypophosphites, Lilly.

*Cordials*—Calisaya, Ferrated; Coca.

*Tinctures*—Ipecac and Opium, U. S. P.; Opium, U. S. P.; Opium, Compound, N. F.; Opium, Deodorized, U. S. P.

*Solid Extracts*—Coca Leaves.

*Powdered Extracts*—Coca Leaves; Opium, U. S. P.; Warburg's Tincture; Warburg's Tincture, without Aloes.

*Elastic Filled Capsules*—Bronchial, No. 1.

*Ampoules*—Cocaine Hydrochloride; Morphine and Atropine (all strengths); Morphine and Hyoscine; Morphine Sulphate (all strengths.)

*Chlorodyne*.

*Compound Cerebral, Sedative No. 1.*

*Dental Preparations*—Cocaine Points; Devitalizing Fibre; Local Anesthetic Solution.

*Glycerites*—Heroin, Compound.

*Inhalants, Lilly*—No. 1.

*Liquids*—Peptones with Coca

*Ointments, Ophthalmic*—Holocaine Hydrochloride.

*Oleates*—Cocaine, U. S. P.; Morphine, 10 per cent.

*Powders*—Ipecac and Opium, U. S. P.

*Solutions*—Cocaine Hydrochloride, 2 per cent, with Acetoform; Cocaine Hydrochloride, 1 per cent, with Acetoform.

*Solvents*—Alum, Compound No. 1; Alum, Compound No. 2; Astringent Wash; Cocaine Hydrochloride (all sizes); Lead and Opium, N. S. Pharyngeal; Uterine Astringent and Antispasmodic; Hydrastine, White Alk. Compound.

*Tablets, French*—Lamorraca, Improved; Morphine and Belladonna; Uterine, Compound.

#### COCA LEAVES, OPIUM AND DERIVATIVES

Anti-spasmodic, Apocodone, Apomorphine Hydrochloride, Coca Leaves, Cocaine and Salts, Codeine and Salts; Codeonal, Dionin, Dover's Powder, Extract Opium, Meconium, Morphine and Salts, Narceum, Nuxecodum, Narceum, Opium Powder, Gum and Natural, Paragon, Papaverine Alkaloid and Salts, Paracodum, Pericodum, Styptol.

#### PATENT MEDICINES.

Remedy, Kansas City; Balsam, Van Werts; Balsam, S. Arnolds Diarrhoea; Remedy, Hegemans Diarrhoea; Chlorodyne, Browns; Pectoral, Wynkoops Iceland; Powder, Daniels Liniment; Syrup, Woods Soothing; Syrup, Jardells Co. Rhei and Blackberry; Compound, Davids Sedative for Cough; Lung Kuro; Anodyne, Browns; Pain Extr., Inghams, 25 cents; Liniment, Bancrofts; Tablets, Waterburys Menth. Cough; Syrup Fahrneys Teething; Rectal Suppos., Liquezone.

PHARMACEUTICALS COMING WITHIN THE EXEMPTION PROVIDED IN THE HARRISON ANTI-NARCOTIC LAW.

*Pills*—Warburg's Tincture (all sizes); Warburg's Tincture without Aloes (all sizes.)

*Tablets*—Cholera Infantum No. 2; Colic Infantile; Pinus Alba, Compound; Warburg's Tincture (all sizes); Warburg's Tincture without Aloes (all sizes.)

*Lozenges*—Brown Mixture; Brown Mixture and Ammonium Chloride.

*Elixirs*—Acetanilide, Compound, Special; Codeine Sulphate; Red Gum, Compound; Terpin Hydrate and Codeine; Terpin Hydrate, Compound.

*Syrups*—Codeine, Compound, Burr; Lobelia and Tolu Compound; Tar, Tolu and Wild Cherry; Terpin Hydrate, Codeine and White Pine; White Pine, Compound, Lilly (and all variations); White Pine, Compound, N. F.; White Pine, Compound, with Codeine.

*Miscellaneous*—Cordial Antiperiodic; Tincture Opium Camphorated, U. S. P.; Tincture Warburg's, N. F.; Tincture, Warburg's, without Aloes, N. F.; Tincture, Warburg's, Modified; E. F. C. Warburg's (all sizes); E. F. C. Warburg's without Aloes (all sizes); Bronchial Sedative, Palmer; Confects Brown Mixture; Liniment Rubefacient; Liquid Coca Leaves free from Alkaloids; Mixture Cholera Infantum; Ointment Hemorrhoidal, Lilly; Ophthalmic Ointment, Dionin 2 per cent.; Ophthalmic Ointment, Dionin and Atropine; Pruniceine.

#### SALE OF DRUG STORE STOCK— FRAUD EVIDENCE

In an action of trespass on the case it was sought to recover, as damages, the difference between the actual cost price of certain drug store stock of goods and fixtures, including a soda fountain, and the cost thereof as represented by the seller at the time of the purchase. The action was based upon alleged false and fraudulent representations of the actual cost price of the fixtures and supplies. The deal was for the capital stock of the

corporation, and not in the specific fixtures or drug supplies. The plaintiff alleged reliance on the truth of the representations. In West Virginia, the plaintiff must prove reliance upon misrepresentations as well as their falsity, though, in some states, reliance is inferred. It was held that the plaintiff had failed to show such reliance. On the contrary, he admitted that he had had twelve years' previous experience in the drug business, had examined the soda fountain, and thought its cost was about what the company had actually paid for it, according to the defendant's representations. Likewise, he also admitted he examined the other fixtures and the entire stock of goods, and that, in his opinion, the cost named by the defendant was not excessive. To quote his language: "From the way the stock looked, and the way it was fixed down in the basement, and all, it certainly appeared to me that there was that much stock," meaning, of course, according to the valuation represented to him. These admissions, it was held, tended to negative reliance by him on the verity of the defendant's representations.

Nor did the plaintiff show, except inferentially, in what respect or to what extent he suffered injury as the result of the negotiations. He admitted that he did not discover the defendant's deception until nearly three years after the purchase. During that time he made no effort to ascertain the actual cost of any of the various items discussed, pending the negotiations. The information secured as a basis for the action, he obtained from the traveling salesman of one of the furnishing companies, who, he says, was frequently at his store during these three years, and through communications by him with the other company. This information was available from the same sources before the final consummation of the deal. This fact alone would not bar his recovery, but it was held to suggest an apparent satisfaction with the transaction. By reason of want of necessary proof, judgment for the defendant was affirmed.

Keller v. Roetting, West Virginia Supreme Court, 82 S. E., 755, decided September 15, 1914.

## WAR DEPARTMENT.

List of changes of stations covering period ending January 31, 1915, in the cases of Sergeants First Class, and Sergeants, Hospital Corps.

### SERGEANTS FIRST CLASS.

Max Weinberg, from the Attending Surgeons Office Port of Embarkation to Ft. Banks.

Ivan N. Karlson, from Field Hospital Co. No. 3 to Jefferson Barracks.

Earl J. Down, from Jefferson Barracks, to Field Hospital Co. No. 3.

Otto A. Tandrop, from Fort Bliss, to the Philippines Department.

Thomas McKelvey, from Ambulance Co. No. 5, to the Philippines Department.

John R. Sands, from Fort Banks, to Ambulance Company No. 5.

Romanus A. LaGrinder, from Plattsburg Barracks, to West Point.

William C. Bonner, from West Point, to the Hawaiian Department.

Dorsey W. Thickstun, from Ft. Huachuca to the Hawaiian Department.

William F. Murphy, from Ft. Missoula, to Ft. Huachuca.

Burton Hardenbrook, from Ft. Leavenworth, to Ft. Missoula.

Samuel Smelsey, from Philippines Department, to Ambulance Company No. 2.

Harry A. R. Kroger, from Casually at Ft. McDowell, to Second Division for assignment.

Charles H. Jorte, from 7th Inf. Hospital 2nd Div., to the Philippines Dept.

Welcome N. Powell, from Ambulance Company No. 2, to Letterman General Hospital.

### SERGEANTS

Meyer McC. Dougherty, from Ft. Screven, to Ft. McPherson.

Bruce D. Gill, from Ft. McPherson, to Ft. Screven.

Joseph Livingston, from Ft. Worden, to Walter Reed, General Hospital.

Michael Fitzgerald, from Ambulance Company No. 8, to Presidio of San Francisco.

John Aue, from Ft. Monroe, to Front Royal Remount Depot.

Frank C. Wagner, from Front Royal Remount Depot, to Ft. Monroe.

Patrick Darby, from Colorado Strike Zone, to Ft. Robinson.

Fitz. W. Donoho, from Ambulance Company No. 7, to Ft. Winfield Scott.

John A. Baker, from the Philippines Department to Ft. McDowell, for discharge.

Lewis B. Houston, from the Transport "Dix," to the Hawaiian Department.

Edwin R. Arndt, from Vancouver Barracks, to Ft. Missoula.

Fay S. Elzey, from Ft. Casey, to Ft. Worden.

### Changes of Address

All changes of address of members should be sent to the General Secretary promptly.

The Association will not be responsible for non-delivery of the Annual Volume or Year Book, or of the JOURNAL unless notice of change of address is received before shipment or mailing.

Both the old and the new address should be given, thus:

HENRY MILTON,  
From 2342 Albion Place, St. Louis, Mo.  
To 278 Dartmouth St., Boston, Mass.

Titles or degrees to be used in publications or in the official records should be given, and names should be *plainly* written, or type-written.

### TITRATION OF HYDROFERRICYANIC ACID.

When ferri- and cyan ion are present, potassium iodide and zinc sulphate are added to the slightly acid solution. The separated iodine is titrated with thiosulphate and starch as an indicator. The influence of ferri-ion is prevented by adding a little KFI solution. Cyan ion being present, some drops of sulphuric acid are added, and the prussic acid is expelled by means of a stream of carbonic acid at 50°. If the gas ( $\text{CO}_2 + \text{HCN}$ ) is brought into a silver nitrate solution, the quantity of HCN can also be determined. F. Muller and F. Seidel (*Zsch. Anal. Chem.*, 1914).

## Section on Pharmacopœias and Formularies

Papers Presented at the Sixty-Second Annual Convention

### MINUTES OF SECTION

The first session was called to order promptly at 9:30 a. m. on Wednesday, August 26, at the Hotel Pontchartrain by Chairman Cook, who in opening the meeting referred to the unavoidable absence of the Secretary, Prof. Needham, on account of sickness in his family, and stated that he had requested Mr. Thum of Philadelphia to act as Secretary *pro tempore*.

The Chairman then delivered his address [printed in September, 1914, issue] and on motion of Prof. Remington it was referred for publication.

The Secretary's report was read and, on motion, it was accepted and placed on file.

Chairman Cook then read the following letter from Dr. Nestor Tirard, the Medical Editor of the British Pharmacopœia:—

74 HARLEY STREET, W., LONDON, ENGLAND, August 8th, 1914.

E. Fullerton Cook, Esq., Chairman Section on Pharmacopœias and Formularies, American Pharmaceutical Association.

Dear Sir: In answer to your letter of July 7th, relating to the British Pharmacopœia, as it was not in my power to send you an advance copy I had hoped to forward you a brief review of the new issue. Now I have to inform you with regret that owing to the grave inconvenience which might result from the introduction of a new standard at the present time, it has been decided to postpone publication.

Very truly yours,

NESTOR TIRARD,  
Medical Editor of the B. P.

Prof. Remington then addressed the Section upon the subject of the Pharmacopœia IX, saying:—

"Mr. Chairman, I do not think it is necessary to present a report at this time in detail of the Pharmacopœia. It is very remarkable that the British Pharmacopœia revision, which has

been coincident to that of our own Pharmacopœia, should have progressed up to the present time.

"I was in London a year ago and Dr. Tirard invited me to meet him—who might be called the Chairman of the Committee on the revision of the British Pharmacopœia. He called me in to see the new British Pharmacopœia. The new features in it are very few. It seems so strange when I think of a year ago and being with Dr. Tirard. I looked at the modest office. It was something like our own pharmacopœia. One had to stop and think a few moments and make a few comparisons.

"I will tell you what has been done, and I think it is of far more importance than it apparently seems. The British Pharmacopœia and the United States Pharmacopœia get together on one practical idea which affects the doctor and the pharmacist equally, and that is to have a table of abbreviations for everything. Abbreviations! Now what do we mean by that? I think you all must realize that in the reading of prescriptions we do not know sometimes, as we read a prescription, what the doctor means. Abbreviations are the real language of prescriptions. No doctor in the world ever writes out now in full a prescription either in Latin or in any other language, particularly in Latin, with all the terminations, correctly. They say life is too short to do that. Every doctor abbreviates. Then why not have a standard and let 'pot. iod.' stand for potassium iodide, and 'sod. brom.' stand for sodium bromide. Now we want to make uniform throughout the English speaking countries this system of abbreviations. In other words, prescription language we want to get together on, and have uniform. It is going to take time. An English pharmacist reading a prescription of an American physician when travelling, will know just exactly what he means and the abbreviation can mean nothing else when it is once established. Nothing of this kind has ever been done before making uniform these abbreviations. The idea, as I developed it to Dr. Tirard, took some little time. He said, 'That is one of the most desirable things we can have.' Then I called his attention to the fact that we can also use these abbreviations for shop furniture. Take, for instance, the question of the relief-clerk; a relief-clerk going to another store is confronted with different abbreviations. Potass bromid,—that is very easy,—potassium bromide, and so on. There is no uniformity now. The manufacturers of labels have their own abbreviations. Each manufacturer of these glass labels has his own idea of how these things should be abbreviated. It is a little practical matter that has not been systemized and brought into line. Here is a little thing that science is getting into, the little matter of abbreviation of the words that are going to be used. We are going to have an abbreviation for any item a physician prescribes, if the doctors still continue to write prescriptions, although I am sometimes doubtful if they will. But never mind; the drug business will survive nevertheless, but we do want to see when we go into stores, a uniformity in the language that is used in designating any articles which are used in medicine.

"I will now come back to the actual work of the pharmacopœia. A very important part of the book which is usually neglected by the pharmacist and the physician. The tables,—you are familiar with them, no doubt,—in the back part of the book, the part called the appendix. This appendix is really the most important part of the book because that is the standard for standardizing the standards; volumetric solutions, tests, and the tables,—everything which is there is really the most important part of the book, because they are the standards which regulate the standards. The front part of the book and the text part of the book are the only parts you are interested in. It has what you want, paregoric, and syrup of squill and other good things you want. But in order to start the work, that it may go on systematically, the committee must have the standards upon which they base their work before them all the time, so we begin at the end of the book; that is, we begin with the appendix and get at all the mistakes that are in that appendix, and then when that is done, the completed appendix, upon which the rest of the book depends, is in the hands of everybody. That part of the book is in the hands of the printer, and I hope in two weeks we will be able to send that out, so it will form the basis for the work.

"We have heard a good deal about the binding of the book. One man has written a letter with regard to binding the book, in which he says the book is all falling to pieces. Well, I asked him how long he had had it. He said he had had it twelve years. I said, 'What use did you put it to?' He said, 'Oh, my pharmacopœia is in use all the time. I have it on my prescription counter.' I said, 'Has it been dusted with permanganate and nitric acid once in a while? Didn't the boys drop it on the floor twice a day on an average?' He said it was a good deal that way. 'A Pharmacopœia twelve years in use, with that kind of treatment, and yet it is beginning to fall to pieces.' I said, 'You would begin to fall to pieces too if you had been knocked about that way for twelve years.'

"We are going to tie it together with four bands. These bands are glued on with glue which has passed inspection and is free from germs and absolutely aseptic. It is to come in around each one of those and to be glued down that on the side (illustrating). The committee hope, if the book is thrown on the floor, on one corner, that the other three bands will hold; that if it don't hold on that corner, then the other three bands will hold it together.

"This idea about the pharmacopœia not being well bound! Why, the book is one of the best bound that has ever been put forth. This criticism is only from people that are hypercritical. I can show you plenty of books that do not get half the use that the pharmacopœia does that have all gone to pieces.

"But I will tell you one thing about the binding that is of concern to you; the worst kind of binding now for anybody to buy for any kind of book is sheep. Sheep binding will not stand because we do not get the leather we used to. The process that is used for tanning will cause it to weaken sometimes inside of a year; at least it becomes tender.

"Now look at this book; solid and unyielding. Where does the strain come? Just on that little bit of a crack, hardly a line in length. The whole thing depends upon that little hinge. I sincerely hope and believe, if we do not have a war, that our pharmacopœia will be out after all within a reasonable time. I think in six months we can see it through the press and get it out. But here! There is the dummy; there is the book only for size; don't look inside because it is all mixed up purposely, but there is the style of binding that I hope you will buy for your own good. It is not made of leather; it is called buckram; that is a cloth especially made, far more durable than sheep and at half the price. This will be on account of the binding, intermediate in price; between the sheep and the cloth. I will pass that around and let you look at it. That is the dummy; it has been adopted merely to show the size of the book and the printing on the outside, and the binding, but I think that binding will outlast two sheep copies anyhow, and, of course, there is the cloth copy (indicating); the printing will be different; the outside will be different. It has been approved by the Board of Trustees and that will be the outward appearance of the new book. This printing will probably be different, so as readily to distinguish one from the other. That will be the color of the buckram, and this will be the color of the cloth. The blue will be the cheaper of the two, and we will have the sheep for those who want it. Now the committee has tried, and it is going to keep on trying to satisfy everyone and every suggestion that has been made on the pharmacopœia we would like to consider, but that is not always possible.

"Now there are two other things,—there may be three; one is the whiskey question, whether it is to be taken up by the pharmacopœia or whether it is not, and I cannot tell you yet what the decision will be. But the decision is growing among a great number of the members of the Association to drop whiskey and brandy from the pharmacopœia entirely and not involve the pharmacopœia in any litigation in the future; drop it entirely. And I think Dr. Wiley is probably quite willing to do that. He has been the great champion of pure foods and pure drugs, but for my own part, I do not hesitate to tell every body what my own opinion is as Chairman of the Revision Committee; I think it was a mistake to put whiskey and brandy into the pharmacopœia Eighth Revision.

"I do feel very greatly relieved, and we must all feel relieved at the prospect of getting out that book. And the people who have been crying about the pharmacopœia all this time do not realize that they will not be the happiest bunch when that book comes out, but the happiest bunch will be the members of the committee and the poor chairman who has been the punching-bag for everybody, but who can then lie down and get a good sleep and get up and eat a good breakfast.

"I haven't anything to say with regard to the book itself because it will be so soon in your own hands that you can see for yourselves. I am only bringing to you here a part of the make-up of the pharmacopœia and to tell you the condition of the revision at the present time.

"The only other question is which of the two organic assays which have been proposed will be accepted, and as to that matter, I am going to have a meeting with Dr. Rosengarten, who is the Chairman of the committee of chemicals and organic chemicals. I met Professor LaWall who was to have been here, but Mrs. LaWall met with an accident and broke her arm and he is compelled to remain in Philadelphia with his wife. We have Mr. Raubenheimer and Dr. Lyons, who is with us at this meeting—God bless him—is one of the committee. Now he was very ill, and he is the man that has given us those tables. He is the mathematician of this committee. I believe Dr. Lyons lives, eats and drinks figures, and I could not be surprised when he gets up in the morning some of these hot days if there is not an imprint of the pharmacopœia on his pillow. But never mind all this; I want to thank him and every other member of the committee. The bow is unstrung and we are so nearly through that I can indulge for the first time in the last five years in some happy thoughts.

"There are other members of the committee here who want to say something, and I am taking the time, but I do hope sincerely that we will have no such set-back as that of the British Pharmacopœia. I hope you who are gathered here to hear about the pharmacopœia will share the attitude and the feelings of the Revision Committee.

"There have been some differences in some of the committees. The members differed and squabbled and fought and lost their temper once in a while. But I know them all. When anybody says anything nasty about anybody else, it goes in the waste-basket, because I won't print anything that is derogatory, or which reflects upon any member of the committee. Some things have not been published, but you can easily see if the doors are open to let in personal feeling and personal views it would not be a valuable book. It is not gotten up to express anybody's personal view, but if in the course of time the members have any difficulty, we have got to straighten it out. We must have harmony and co-operation or we could not get along. We have had it and we are nearly through, and I do not think there is any liability of any very big trouble. We have been very strenuous about expressing our opinions, but after all, I think we will have a pharmacopœia that will meet with the approval of nearly everybody." (Applause.)

CHAIRMAN COOK:—"I am sure we have been very much enlightened by this informal and interesting report of the Chairman of the Revision Committee. It will now be in order to hear any discussion on this question of pharmacopœia. All questions that anyone wishes to ask, no doubt the Chairman of the Committee will be glad to answer or explain any point."

PRESIDENT BERINGER:—"I do not think the druggists or many of the critics have any idea at all of the volume of work that has been necessary in making up the standards that go to make up the pharmacopœia. I find difficulty in reading them all, and I guess most of the members do."

MR. THURSTON:—"I would like to ask Prof. Remington a question. In the old pharmacopœia we had a number that was pasted in,—an official number for each copy. I would like to know if some method could not be devised to publish an official certificate in each copy so that it would be taken as authority in cases at law. I have had cases where they would question the pharmacopœia. For instance, they would say, 'How do you know that is the Pharmacopœia of the United States?' Well, I wasn't on the committee to prepare the pharmacopœia; I didn't help write it, and there was no way for me to swear that that was absolutely the Pharmacopœia of the United States. There should be some method, if possible, so that in cases of that nature that we could prove that the book that we testified to was the Pharmacopœia of the United States."

PROF. REMINGTON:—"I certainly appreciate the remark by my friend Prof. Thurston, and this is what he refers to, I think; this is the old pharmacopœia,—that little label there; that coupon we call it; that little coupon there on that page. Now, that was never gotten up with the idea of proving the identity of the pharmacopœia, but that idea originated with Dr. Charles Rice in the previous pharmacopœia, of pasting a coupon in the book which simply read 'The Pharmacopœia of the United States of America; official copy,' and then it is numbered serially, and they are all taken up in issues. For instance, there is 'A,' meaning 20,000 copies of the pharmacopœia, ordered first; Series B, meaning the next 10,000, or Series C, the next 10,000, or 5,000, as the demand tapered off. There was one published, and I will say that the same publisher will publish the new pharmacopœia that published the last. These coupons are used between the printer and the publisher so that the coupons here were furnished at the last revision and now they will be furnished by a Board of Trustees. The Secretary, Mr. Whelpley, will furnish the coupons for this edition, and he has charge of those. He issues 20,000; he sends to the publishers 20,000 and they send 20,000 to the printer to paste in the book at the time that issue goes out, and they are all numbered from one to 20,000. Now when Series B comes, then it will be the second issue."

"As to the point of Prof. Thurston, I do not see how the use of a label or the use of anything in the book itself would be regarded as evidence that it really was the pharmacopœia, if a man wanted to cheat,—if he wanted to get up something to imitate the pharmacopœia, or leave something out, or put something in, and the lawyer wants to know if that is really the pharmacopœia."

MR. HOSTMANN:—"That question was raised in New Jersey some years ago in a suit in one of the lower courts. The lawyer wanted evidence that that was a copy of the pharmacopœia. The Judge was about ready to throw the case out. Then there was an agreement made between the two attorneys, and the court decided that the only way that that book could be admitted as evidence was to secure an attested copy from the Library in Washington. I believe it is the Library,—the Congressional Library of the United States, and the State's attorney went to Washington, and there they produced a copy of the pharmacopœia and it was endorsed on the inside on the second page 'Registered in the office of the Librarian of Congress at Washington.' There was an official seal there and the Librarian's signature that that was a true copy of the United States Pharmacopœia. That was only in the lower courts there, but I believe that is the regular procedure if you want to use the book as testimony; you will have to have it attested by the Librarian at Washington, that it is a true copy of the book. I imagine that is the only way it can be done."

MR. RACHENSTEINER: "I can see it will be an immense benefit and it will certainly increase the weight of the pharmacopœia in court if the statement was made on the title page that this book has been made the legal standard of the United States. I think such a statement would certainly have some weight in court; not only in court, but it will have weight in the other courts. I believe there are still some men scattered throughout the country, perhaps in New York, perhaps in this city, that don't know the U. S. P. and the N. F. has been made the legal standard. I believe that would be a pretty good idea. It might also increase the weight by having perhaps the stars and stripes or an American eagle or something like that on the outside. It would impress probably the public as well as the pharmacists, and even the lawyers."

The report of the Committee on the U. S. P. was read by Prof. L. D. Havenhill. [Printed in September issue.]

CHAIRMAN COOK: "I would suggest that as the Pharmacopœial Revision Committee are going to have a meeting this afternoon, that a motion be made for the receiving of this paper and that it be referred to that committee for consideration." It was so ordered.

PROF. REMINGTON: "I just want to say a word. There was a point brought up by Mr. Havenhill about expensive apparatus. The committee have considered the matter very carefully. For instance, on electrolytic methods, which cannot be performed by the pharmacist;

the committee realizes that this book now is the standard for the United States; it is the standard under the food and drugs act, and anything like dropping from the pharmacopœia a decisive and valuable test like the electrolytic test, and give it up because the clerks in the drug stores cannot get the apparatus, or because the students in the colleges cannot use it, is not to be considered. We cannot afford, with a book that is authority for the United States, to consider that all we have got to think about is the student. The pharmacopœia was not made and is not made for the student. It is not its function either to cater to the retail druggist. It is, though, the prime object that the test shall be as simple as possible; and the pharmacopœia cannot be limited in scope, now that it is the standard for the United States, to the non-education of some clerk in a drug store.

CHAIRMAN COOK:—"The next order of business is the report by Prof. C. Lewis Diehl, of the National Formulary Committee."

## REPORT OF THE COMMITTEE ON NATIONAL FORMULARY.

C. LEWIS DIEHL, CHAIRMAN.

The efforts of the National Formulary Committee throughout the year have been chiefly directed toward the perfection of the final text. This has been reproduced as edited copy in the Committee Bulletins, and has included the majority of articles proposed for Part II, which have been prepared by the Committee on Unofficial Standards.

A set of formulas and articles proposed for the book have also been prepared in manuscript form so that Part I (formulas) and most of Part II (drugs or chemicals) are practically in readiness to turn over to the printer when the contract is awarded.

A conference of the Committee has been called, to extend over possibly two days, following this meeting of the Association, and it is expected that the final manuscript will be perfected at that time.

As bids have already been received by the Committee on Publication for the printing and binding of the book and the contract will no doubt be awarded by the Council before the close of this meeting, it can be confidently expected that the National Formulary, Fourth Edition, will make its appearance within the next six months and certainly not later than the appearance of the U. S. P.

On motion it was referred for publication.

CHAIRMAN COOK:—"The next report is one by Mr. George M. Beringer, Chairman of the Committee on Unofficial Standards. [Printed in November issue]. You have heard this report. If there is no objection it will take the usual course."

MR. HYNSON:—"May I ask if you, in including all this work in the National Formulary, regard it as the proper place for it?"

MR. BERINGER:—"It seems to me in answer to that inquiry, Mr. Hynson, that it is absolutely necessary to protect the National Formulary as a legal standard; that it should include proper tests and define its standards and its formulas. We have always believed they were there, but they are not there. It is up to us to supply them. We have discussed it back and forth in the committee and we have all come to see the necessity of its being there."

"The Food and Drugs Act says The National Formulary. You cannot amend the food and drugs act of the nation and the food and drugs act of the various states by simply changing the name; you must retain the title of your book."

MR. HYNSON:—"I meant as a supplemental title."

MR. BERINGER:—"The main title of the National Formulary must remain."

MR. RAUBENHEIMER:—"In a way I believe Dr. Hynson is right. A National Formulary, as such, must retain the present title inasmuch as the pure food and drugs law simply states the standard in the U. S. P. and the N. F., and so on. In time, I have no doubt, this committee on standards will standardize all things."

MR. HYNSON:—"The idea is brought out by Mr. Raubenheimer. I would like to say, after a great deal of thought and consideration—I have to think over things very hard and very long to get a good understanding of them—that I don't know any work that the American Pharmaceutical Association has done that is so creditable and is so much in use, and that

there is so much promise in it as there is in this work. I believe it is the beginning of the most stupendous work of the American Pharmacist. Everything changes and I think the day will come when we will see a book of standards which will be the outgrowth of this work and will far exceed in importance the United States Pharmacopœia. I want to say, however, that that belief is simply a personal belief, but I do believe it will not be two decades before the physicians of this country will entirely ignore the United States Pharmacopœia.

"I want to say a word in appreciation of this work; that I believe it is of such a character and a work that has required so much care and attention that it ought to be brought out distinctly; let it be known that the National Formulary, beside being a book of formulas is a book of standards. I do not believe that that can be done well except by making a supplemental title, if that be legal. But I want to set forth my appreciation of the work and my belief that we hardly know what has been begun in this direction."

MR. BERINGER:—"I would like to call the attention of the Association to the fact that a great deal of the work which the Committee has actually done has been up-hill work. Much of the work the committee did became valuable to the Pharmacopœia and I believe it is indeed a very happy condition that we have had such coöperation on the part of the different committees."

MR. KIRCHGESSNER:—"Do I understand, Mr. Hynson, that we are to have a supplemental book before it goes into the National Formulary?"

MR. HYNSON:—"No, I did not mean that, because we have to retain the legal character of it, but I would like to see it, as far as possible, brought out that there are things in the book that are not standard and a great many that are standard."

MR. HYNSON, Chairman of the Recipe Committee, read the report of that Committee. [Printed in September.]

MR. ENGLEHART:—"I move that this very excellent report be received and the recommendations contained therein be referred to the Chairman."

Motion seconded and carried.

CHAIRMAN COOK:—"It will be received and the recommendations referred to the Council for action."

"We have about ten minutes at this point for discussion of this paper. It is an excellent report and an ideal condition that we hope will develop."

MR. RAUBENHEIMER:—"There is no doubt in my mind that Chairman Hynson has given this subject much more thought than perhaps any of us. I hope he will remain the Chairman of that committee, because he understands it much better than I do. In time, he will convince all of us that he has the proper idea of what the ideal recipe book should be, and no doubt it will be of great benefit if such a book is published only in part, as a supplement to the journal. We have too many books of formulas, but we have no reliable ones. It is necessary and it is the duty of the A. Ph. A. to take the initiative step to bring about such a book of which Prof. Hynson is the father."

MR. BLAKESLEE:—"I just want to say a word on this subject, a fact that Mr. Hynson or perhaps others have not considered. I observe in every section of the country the attitude of the retail druggist in regard to their desire for information such as Prof. Hynson proposes, and it is alarming to see what a demand there is for reliable formulas; how at sea the retail druggists are for information of that kind. There is a class of formulas that could be recommended by intelligent pharmacists, such as Mr. Raubenhaimer and Mr. Hynson, and others; therefore it would be a clearing-house for certain large manufacturers. I am sure it would be a source of great value to them if some such publication of that kind were brought out, and I hope Mr. Hynson will never let up until he gets his idea in some sort of tangible form."

A paper by Dr. Bernard Fantus entitled, "Can the U. S. P. and N. F. be Made Popular With Physicians?" was read and referred for publication. [Printed in this issue.] Adjourned until Friday, August 28.

#### SECOND SESSION, FRIDAY, AUGUST 28, 1914.

The meeting was called to order by Chairman Cook at 9:30 a. m.

PROF. RAUBENHEIMER:—"I move that the reading of the minutes be dispensed with."

Motion seconded and carried.

CHAIRMAN COOK: The first subject on the program is a review of the Norwegian Pharmacopœia, by Dr. M. I. Wilbert.

## THE NORWEGIAN PHARMACOPŒIA.

---

M. I. WILBERT, PH. M.

---

The fourth edition of the Norwegian Pharmacopœia, or as it is officially known "Pharmacopœa Norvegica, 1913," became official on January 1, 1914, replacing the former third edition of the book which was published in 1895.

The new pharmacopœia consists of a total of XIII and 467 printed octavo pages, 362 of which are given over to the description of official drugs and preparations. The official monographs include 543 titles, of which number 17 are general headings, 149 are drugs, including 15 of animal origin, 169 are chemical substances and 208 pharmaceutical preparations.

The prefatory pages include the royal proclamation of February 7, 1913, announcing the publication of the book and the date on which it is to become official, a review of the contents, a short prefatory note by the members of the commission in charge of the revision and the outline of general methods for determining physical and chemical constants. These general methods include directions for the determination of temperature, specific gravity, solubility, melting point, boiling point, polarization, iodine number, acid number, ester number and other constants. This portion of the book also briefly outlines the methods to be followed in collecting and preserving plant drugs.

The text of the pharmacopœia is printed in Norwegian and only the titles of the several articles are in Latin. In compliance with an existing agreement these Latin titles are similar to those in the other Scandinavian countries, Sweden and Denmark, and are generally quite distinct from the titles appearing in the pharmacopœias of other European countries; the older Berzelian method of giving preference to the acid radical in connection with chemical substances being generally followed.

The monographs for drugs, particularly drugs of vegetable origin, are concise and clear and the same can be said of the monographs for chemical substances. In connection with the latter class of articles the chemical formula and also the atomic weight where reasonably available is usually given. This is modified somewhat in the case of acids and other solutions to indicate that those substances are more or less variable. Hydrochloric acid, for instance, is given  $\text{HCl.Aq.}$  with the requirement; 100 parts contain 25 parts of hydrogen chloride ( $\text{HCl}=36.47$ ).

In common with the pharmacopœias of the two other Scandinavian countries this book includes what may be characterized as a pharmacopœial joke. Under the heading "Glaciers" and the Scandinavian "Is," the equivalent of the English "Ice," is a blank space evidently intimating that any attempt to describe the substance would be useless.

As an illustration of the recognition that has been accorded to newer researches, more particularly the possible influence of enzymes on the activity of plant drugs, it will suffice to call attention to the requirements for digitalis leaf. This drug is to be collected from the indigenous, wild growing plant at the time of flowering, is to be dried for at least five hours at about  $80^{\circ}$  and preserved in small, well-closed containers holding about 50 gms. of the drug.

The Norwegian Pharmacopœia has, of course, been liberally discussed in European countries and differences of opinion have been evidenced particularly in regard to the scientific character of the book. A writer in the *Chemist and Druggist*, London, for instance, expresses the opinion that "The book is not a particularly up to date publication," while the reviewer in the *Lancet* opines that "The new work embodies many features of modern research in pharmacy and testifies to the high scientific attainment of Norwegian pharmacists." The German reviewers generally find much to commend in the book, largely perhaps, because it is considered to be distinctly in keeping with the German pharmacopœia. The descriptions of crude drugs and of chemicals are generally commended, and Schimmel & Co., in their Semi-Annual Report for October, 1913, express the opinion that the requirements included in the monographs for essential oils are generally reasonable and in keeping with our present-day knowledge regarding this class of products.

The galenical pharmacy is perhaps not as thoroughly up to date as one might have expected, a considerable number of complex pharmaceuticals have been retained from former editions of the pharmacopœia and several equally objectionable preparations were included as new remedies. Among the latter is the compound syrup of hypophosphites, a complex preparation that has been the cause of considerable dispute in our own country.

General articles descriptive of the several classes of galenicals have been included and these usually describe the methods to be employed in making and preserving the various preparations. In connection with fluid extracts and tinctures, the color, specific gravity and extract content of the several preparations is given.

A liberal number of assay requirements have been introduced in connection with the preparations of alkaloidal drugs, but the requirements are not stated at all uniformly and in connection therewith some rather liberal variations are permitted. Thus extract of *nux vomica* may vary from 15 to 17 *per cent.* of total alkaloids and extract of opium from 18 to 20 *per cent.* of morphine. The tincture of *nux vomica* may vary from 0.25 to 0.30 *per cent.* of total alkaloids but the tincture of opium is to contain *about 1 per cent.* of morphine and fluid extract of *hydrastis* is to contain *not less than 2 per cent.* of hydrastine.

Among the newer remedies that have been added we find acetylsalicylic acid, diethylbarbituric acid, camphoric acid, bromoform, ethylbromide, creosote carbonate, eucalyptol, eugenol, hexamethylenetetramine, cresol, novocaine, amyl nitrite, silver proteinate, antipyrine salicylate, mercury salicylate, solution of formaldehyde, and the several hypophosphites used in the making of compound syrup of hypophosphites. It will be noted that at least several of these articles are no longer considered new remedies with us in this country, while others have never secured sufficient recognition on the part of the medical profession to warrant their being included in our own pharmacopœia.

The requirements of the Brussels Conference Protocol have been generally followed rather closely. The protocol itself is reproduced in tabulated form and the articles that have been included in the pharmacopœia itself are designated by the addition of the letters P. I. to the sub-titles which are those included in the international treaty.

Table showing the international standard titles included in the Norwegian Pharmacopœia, 1913:—

- Acidum Hydrocyanicum dilutum P. I.  
 Amygdalæ amaræ aqua s. Aqua amygdalæ amaræ P. I.  
 Belladonnæ extractum s. Extractum Belladonnæ P. I.  
 Belladonnæ folium s. Folium Belladonnæ P. I.  
 Cocainum hydrochloricum P. I.  
 Colchici semen s. Semen Colchici P. I.  
 Colchici tinctura s. Tinctura Colchici P. I.  
 Digitalis folium s. Folium Digitalis P. I.  
 Digitalis tinctura s. Tinctura Digitalis P. I.  
 Ferri jodidi sirupus s. Sirupus jodeti ferrosi s. Sirupus ferri jodati P. I.  
 Hydrargyri unguentum s. Unguentum Hydrargyri P. I.  
 Hyoscyami extractum s. Extractum Hyoscyami P. I.  
 Hyoscyami folium s. Folium Hyoscyami P. I.  
 Ipecacuanhæ radis s. Radix Ipecacuanhæ P. I. .  
 Jodi tinctura s. Tinctura Jodi P. I.  
 Kalii arsenicosi liquor s. Arsenicalis liquor Fowleri s. Liquor arsenicalis  
 Fowleri.  
 Opii et Ipecacuanhæ pulvis compositus s. Pulvis Doveri P. I.  
 Opii extractum s. Extractum Opii P. I.  
 Opii Tinctura s. Tinctura Opii P. I.  
 Phenoli solutio s. Aqua phenolata P. I.  
 Secalis cornuti extractum s. Extractum Secalis cornuti; Ergoti extractum s.  
 Extractum Ergoti P. I.  
 Secalis cornuti extractum fluidum s. Extractum fluidum Secalis cornuti; Ergoti  
 extractum fluidum s. Extractum fluidum Ergoti P. I.  
 Secale Cornutum s. Ergotum Secale P. I.  
 Strophanthi tinctura s. Tinctura Strophanthi P. I.  
 Strychni extractum s. Extractum Strychni; Nucis vomicæ extractum s. Extrac-  
 tum Nucis vomicæ P. I.  
 Strychni semen s. Semen Strychni s. Nux vomica P. I.  
 Strychni tinctura s. tinctura Strychni s. Nucix vomicæ tinctura s. tinctura  
 Nucis vomicæ P. I.

The appendix includes a number of tables, among others: An atomic weight table of the elements referred to in the pharmacopœia based on the international atomic weight table for 1910; a list of the reagents used in testing drugs and medicines, also a list of reagents for tests and stains used in the clinical laboratory; a table showing the specific gravity of solutions of acids and alkalies at 15°, a table showing the number of drops in a gramme of several frequently used official preparations when dropped from the official normal drop counter at 15°, a table of the maximum doses of active medicaments, a list of poisonous articles that should be kept in the poison closet apart from other medicines, and a list of potent medicines specially designated in the body of the book that are to be kept separated from other articles; a list of the articles added to the fourth edition of the pharmacopœia and a list of the articles in the third edition, but not continued in the fourth edition. These several tables are followed by a reprint of the Brussels Conference Protocol and by two indices, one an index of the Latin titles with the sub-titles from the International Protocol and the other an index of the Norwegian names. The index of the Latin titles also includes under the several official names of the drugs and chemicals a list of the preparations in which the substances are directed to be used.

Altogether the book impresses one as being an earnest attempt to solve pharmacopœial problems in an up-to-date manner. The directions and requirements appear to be reasonable, and the general consensus of opinion of writers and reviewers is to the effect that the book furnishes satisfactory standards for the articles enumerated in it.

In the limited time that can be devoted to a review of this kind no elaborate critical review of the book can be presented, but enough has been said to justify the statement made by the reviewer in the London *Lancet* that the work embodies many features of modern research in pharmacy and testifies to the high scientific attainment of Norwegian pharmacists.

#### DISCUSSION.

MR. RAUBENHEIMER:—"It is certainly gratifying to become acquainted with some of these foreign pharmacopœias, even if we are unable to read them. I would like to ask Mr. Wilbert what edition this pharmacopœia is, in the first place, because that is quite important. I also want to point out that the nomenclature of the Scandinavian pharmacopœia is also used by the Netherlands pharmacopœia. Of course, this nomenclature is entirely different and confusing with the tables of the U. S. P., and you will have to get used to it in filling foreign prescriptions.

"There is one important item I also want to call attention to. I had a call for this from one of the professors in Highland College. It was a Norwegian prescription and it was rather a peculiar preparation. I looked it up for him and it happened to be *spiritus ammonii carbonici pyro-oleosi*. That was the old spirit of hartshorn. Instead of being distilled from the horns of deer, as done by our forefathers, and which process, I suppose, was official, it is now made by taking ammonium carbonate, and in order to give it this pungent, disagreeable, empyreumatic odor, adding a small amount of ethereal animal oil, the ill-smelling empyreumatic oil distilled from bones, etc., discovered by the Berlin alchemist Dippel. That makes practically the same thing as the old spirit of hartshorn, which is still used in medicine to day in some countries.

"Regarding the nomenclature, I have no doubt Mr. Wilbert has in his paper the odd titles *ætheroleum* and *pyroleum*. The former applied to 'essential oils,' and the latter to 'empyreumatic oils,' and they are very wisely intended to separate these oils into classes by themselves.

"From the review of foreign pharmacopœias the pharmacist can always learn something, and even the members of the Revision Committee of the U. S. P. can receive and conceive valuable suggestions, which may be applied to our own pharmacopœia."

Dr. Wulling stated the matter referred to by Mr. Raubenheimer was one of the subjects the International Pharmaceutical Congress has before it and he thought a proper solution of the subject could be brought about in time.

President Beringer stated he believed the American Pharmaceutical Association had a committee that was giving attention to this matter. The question of titles was one that was prevalent, but there was, nevertheless a practical side of that question. He stated that every pharmacopœia has been made to suit the medical practice and customs of its own country. Now, to change the title under which mixed drugs are to be prescribed in a country, is likely to cause confusion, and he believed the U. S. P. has as pure a system of nomenclature as any of the foreign pharmacopœias; that on the whole he believed our titles to be as pure in following a distinct system of nomenclature as any of the pharmacopœias, and to change the title would really be of no benefit but only lead to confusion.

Chairman Cook stated it was interesting to say, in connection with the subject of international agreements, that the present pharmacopœia revision committee has cooperated with the British Pharmacopœial Committee on uniform abbreviations, and that with very few exceptions abbreviations will be uniform in Great Britain and in the United States.

Dr. Wilbert, in answer to a question propounded by Mr. Raubenheimer, stated the present Norwegian pharmacopœia is the fourth revision, published in 1911. The Scandinavian system of nomenclature, which is the earliest, is adopted also in good part at least in the Belgian pharmacopœia, and as Mr. Raubenheimer said, it occurs also in the Dutch. The matter of foreign titles, he thought, was an important one. Personally, he thought it would have been an advantage as an educational factor to include in our own pharmacopœia the synonyms of the most widely used titles.

President Beringer read a paper entitled "The Review of the New Homeopathic Pharmacopœia" [Printed in February issue.]

CHAIRMAN COOK: "If there is no objection, I am going to ask that the exhibition of crude drugs be presented next, and following that, the exhibition of preparations. The crude drugs are supplied from the University of Minnesota, and Prof. Newcomb not being able to remain, we will listen to a statement with regard to them by Prof. Wulling."

PROF. F. J. WULLING:—"Mr. Chairman and Gentlemen: The exhibit before you consists of drug specimens grown and produced in the Medicinal Plant Garden and the Medicinal Plant Laboratory of the College of Pharmacy of the University of Minnesota. The time is limited and instead of giving you a formal address on the subject of medicinal plant cultivation, I will speak only a few minutes on the subject.

"The crude drugs exhibited before you are the bases of many of the preparations which will be the subject of discussion immediately following. The exhibit before you is not as creditable a one as we could have prepared had time permitted. The more important of the drugs included in the exhibit are as follows:

Digitalis, U. S. P.  
 Digitalis lutea  
 Digitalis ferruginea  
 Digitalis lanata  
 Digitalis grandiflora  
 Datura Stramonium  
 Datura tatula  
 Datura Stramonium, stems, powdered  
 Datura tatula, stems, powdered  
 Datura metelloides  
 Datura metelloides, stems, powd.  
 Datura fastuosa, cerulea  
 Datura metelloides, seed, whole  
 Datura Stramonium, seed, whole  
 Datura levis, seed, whole  
 Datura fastuosa, alba  
 Valeriana, U. S. P.

Salvia, U. S. P.  
 Marrubium, U. S. P.  
 Chenopodium  
 Levisticum  
 Belladonnae Folia  
 Symphytum Leaves (Adulterant of Digitalis)  
 Verbascum Leaves (Adulterant of Digitalis)  
 Althaea Leaves  
 Taraxacum, U. S. P.  
 Coix Lacryma, fruits  
 Humulus, U. S. P.  
 Cannabis sativa  
 Capsicum  
 Inula, root  
 Coriandrum, U. S. P.  
 Conium, U. S. P.

"It occurs to me that the exhibit explains itself in a way and that it might be more interesting to you to learn something of the introduction of this kind of educational work into the curriculum of a pharmaceutical educational institution. Those of you who are sufficiently interested to desire information about the drugs exhibited are asked to read the labels on the respective containers. Much information will be found there.

"I have been asked here, whether I think it is proper for a college of pharmacy to undertake the production of crude drugs. I reply that it is perfectly consistent, indeed, I believe essential, for the best and fullest kind of pharmaceutical instruction for colleges of pharmacy to add medicinal plant gardens to their equipment to strengthen the curriculum. We are very careful to emphasize that we do not cultivate medicinal plants in a commercial way, but we do stimulate especially the coming pharmacists to endeavor to prepare for themselves some of the crude drugs which it has been found upon research and experiment to be possible for them to cultivate satisfactorily.

"Our present medicinal plant garden occupies an area of a little over two acres and was begun about five years ago. Our first garden was begun in 1893, but on account of lack of time and money we did not go on with it. A few years later I used a good part of the plot of ground adjoining my residence in the rear, for drug plant cultivation but this did not prove satisfactory. Somewhat later, the University authorities became more disposed to consider a plant-garden and finally were prevailed upon to allow a sum of money for a garden and to designate a site. Indeed, so interested did the authorities become in the project that they insisted that I visit the more important botanical and medicinal plant-gardens of Europe and this country. I gathered much information from the gardens at Paris, Berlin, Marburg, Munich, London and elsewhere. Much of the information thus gained has been used in a practical way at our College. Dr. E. L. Newcomb, who had had some experience in horticulture and greenhouse work, was secured to carry on the work in pharmacognosy and to carry out the plans for the garden. His services have been very helpful along these lines.

"In order to employ the fullest facilities of the garden, a medicinal plant greenhouse and laboratory was erected immediately adjoining the Pharmacy Building and connected with it by a passageway. This laboratory is unique and is the only one of the kind I know of. It is 32 x 61 feet in dimensions, has a full cemented basement, in which are contained a complete milling-plant, consisting of fanning-mills, disintegrators, limited powdering-mill, thresher and sifters, all operated by individual electric motors. Five spacious drug-drying ovens are used in this basement, together with a series of portable steel drug containers. A separate drying room and a root-cellar adjoin the main basement room. The superstructure is the greenhouse proper, the central portion of which is devoted to a pyramid on which are placed the perennial and some potted annual plants. The lantern is high enough to admit of the cultivation of trees, such as a small sized eucalyptus, tall shrubs, etc. Surrounding this pyramid are cement work-tables for sixty students. An aquarium is also provided. The department of pharmacognosy is located in the Pharmacy Building on the side nearest the plant-house so that communication between the two floors of the pharmacognosy department and the plant-house and the garden is most convenient.

"Some of the plant seeds are sown early in March or late in February in the plant-house. At the proper time the young plants are taken from the pots in which the seed was sown broadcast and placed into flats where they are allowed to develop until they are large enough to be transplanted into individual pots in some cases, or until they may be planted in the open in the garden. In the garden the necessary care is given to the needs of the individual

plants to the end that the best possible crop of each is secured. Most of the crop is not ready for gathering until the students return in September. The students do most of the harvesting, drying, assaying, powdering and preserving of the drugs, of course under proper direction and supervision. The work is not done in any haphazard way. In drying the harvest, for example, some drugs are dried by gas heat, others by steam heat. Full data are kept of the moisture before, and at stated times during the drying. The temperature is always under proper regulation. Certain of the drugs are subjected to assay and to other pharmacopœial tests, before they are finally declared ready for conversion into preparations in the pharmacœutical laboratories. We have found that most of the drugs we have undertaken to cultivate, meet the pharmacopœial requirements, and in some cases exceed them. Our digitalis, for example, so far has met, at the end of the first year, all the requirements exacted of the official drug. In this connection, it should be remembered that we begin cultivation in the plant-house early in March. No doubt other regions could demonstrate equally, that with proper care and conditions digitalis could be grown elsewhere in one season that would meet the two-year's requirement of the Pharmacopœia and thus much could be gained.

"This kind of work is, of course, still in its initial stage. So far we have not published any bulletins covering our research work along these lines, but we expect to be able to issue such bulletins soon. The interest in this kind of work is very pronounced. Within a period of about a year following the beginning of our work, we had several thousand letters inquiring how to grow some of the medicinal plants commercially. Some of the correspondents inquired for full information as to how to make a profit of from three to four thousand dollars per acre. We replied to all letters emphasizing the need of more than a mere agricultural training in the cultivation of medicinal plants, and we discouraged them, as we do now, this kind of cultivation by all who have not had some special pharmacœutical or medical training. However, we are advising pharmacœutists to look into the matter and cultivate some plant drugs. We have advised some to cultivate such drugs as peppermint, spearmint, horehound, ginger, etc., even if they have not the courage to cultivate the more potent medicinal plants. There is no doubt in our minds that more money could be made by the cultivation of some of the commoner medicinal herbs, than could be made from the cultivation of potatoes or wheat. The point we emphasize is, that the cultivation of toxic medicinal plants ought not to be carried on by others than pharmacœutists or by those similarly qualified. We tell the farmers it is necessary for the successful cultivation of such drugs as digitalis, belladonna and stramonium, to have some pharmacologic training. The average farmer has not sufficient qualification without further preparation to cultivate drugs.

"It is not necessary for colleges of pharmacy to have an expensive plant in all cases for the cultivation of the more representative drugs. While we have expended something over \$25,000.00 on our department of pharmacognosy, including the plant garden and plant laboratory, some institutions are doing creditable work with a much smaller and less representative equipment. Our beginning was a very modest one, but by perseverance we have finally been able to develop it to a certain degree. We found the greatest difficulty in creating a favorable sentiment for this kind of work among the authorities. When that was overcome, the rest followed naturally. Possibly others would succeed similarly if they made the beginning."

MR. MAYO:—"In view of the very great shortage in our supply of the drugs grown in Europe, it seems to me we ought to pay some attention to the immediate future supply, especially to such as are available in our own fields. I know we have a good many drugs that are indigenous growing in various sections, which we have not cultivated for various reasons. I am under the impression that, at the very high prices which now prevail, we won't have to convince the farmers of the advantage in cultivating some of these drugs. It might be well for this Association to see whether it is not feasible to make good at least a part of this shortage by a collection of indigenous drugs. I therefore move you, as carrying out this idea, that this section recommend to the general session that a committee of five be appointed to investigate the feasibility of a collection of this year's indigenous drugs to supplement the foreign supply, and to take such steps as may seem to them to be proper without incurring any expense to the association. The department of agriculture have issued bulletins on this subject and they might be very glad indeed to cooperate with us.

"I believe this Association should take the initiative and I therefore move you that the section recommend to the general session that a committee of five be appointed to investigate the matter, and if feasible, agitate for the collection of botanical drugs."

CHURMAN:—"You have heard this motion, which is a very excellent one at this time because of the very peculiar condition of the market."

DR. SCHREIBER: "I second the motion. In addition to this idea advanced by Mr. Mayo in his motion, I would like also to call more specific attention to the advisability of entering into the growing of medicinal plants right here in the United States as a commercial proposition. I have worked out in every detail the growing of belladonna as it should be grown, along the Pacific coast. To this end we have devoted I should say, roughly, about five or six thousand dollars, and I have put into it perhaps some five or six years of my time. So far we have sold perhaps, estimating it roughly, some fifteen tons of belladonna. I think I could get as much as five dollars a pound for belladonna if I had it, but I have not got it. The price of

belladonna in the past has been so low we could not compete successfully. I think the motion should include also an instruction that the committee should look into the cultivation of the plants."

MR. MAYO:—"I will gladly accept that as an amendment."

CHAIRMAN COOK:—"You all understand the motion, I think, that a committee of five be appointed to look into the question of collecting and cultivating indigenous medicinal drugs and other drugs than those indigenous to assist, if possible, in relieving the drug market."

The motion was adopted.

CHAIRMAN COOK:—"The time has come now for the consideration of the exhibit which is before you. I would like to say a word or two about this exhibit, its purpose, the manner of collection of the samples, and the way in which I hope we can gain some benefit from its consideration.

"As you all know, the United States Pharmacopœia, 9th revision, and the National Formulary, 4th edition, are practically completed in their revision. The formulas which are proposed for inclusion, are available, and many of them have been published. The books are practically ready to print to-day. It was suggested that, at this section, we could be of great help to the committee of revision and the members of the association who were present would be very much interested no doubt in seeing an exhibit of the new preparations proposed, and those older preparations which have been modified. With that in view, a number of pharmacists, fifty or more, were asked each to prepare six preparations. We had excellent responses from these requests; I think all but about four, who had legitimate excuses, complied. The preparations on this row represent those made by the pharmacists very recently. The preparations on the three lower shelves are those which have been contributed from time to time by the sub-committees of the Revision Committee to substantiate their reports. Some of them are two, three and four years old. This exhibit was undertaken with a view then of giving the pharmacists here an opportunity to see what these preparations were, for the purpose of trying to clarify a few points which have been severely criticized and also for subsequent exhibition in association work. Anyone who is interested in having this exhibit for one of their meetings this winter, can arrange for it.

"It is the intention here this morning to select from this set of specimens a small group, ten or possibly fifteen, depending upon the time which we have, of these preparations which have been especially discussed, and about which there is some question as to the formula. Reports have been sent in,—quite a voluminous series of reports from all the pharmacists who have made these preparations. I have selected a group of about ten which we will take up first. When these have been given adequate consideration, and it must be limited to ten minutes or we will not be able to get through, we will then take up others if there is any time remaining. If you have any suggestions, may I ask you to write them out now and hand them to me? All of these recommendations will be transferred immediately to the revision committee.

"The first preparation I wish you to consider is the preparation of Syrupus Ferri Iodidi, which has been modified to the extent of omitting the dilute hypophosphorous acid as a preservative. Two samples have been submitted, one from Philadelphia, and one from Massachusetts. I have also a sample by Mr. Beringer. The results are before you. Apparently the new modification is a very great advantage.

"The next preparation I wish to have you consider is Magnesiae Magma. This preparation was formerly in the National Formulary. It has been introduced now into the United States Pharmacopœia. The formula that has been approved is one that was adopted by the National Formulary Revision Committee before it was known the United States Pharmacopœia would adopt the preparation. I have here five samples made up by this new formula. Has anyone anything to say of this preparation? The new formula has been published in the Journals in the last few years. This is a modification of the present National Formulary formula, and I should be glad to hear anyone discuss this in assisting the Revision Committee to a final conclusion."

MR. HOSTMANN:—"The main objection I have to Mr. Beringer's formula was the long time of washing and the quantity of water required. I do not believe it is necessary to wash with distilled water. If you want a white preparation, it is necessary to have water that is absolutely free from iron. When we were working on it, we took a large quantity of hydrant water, boiled it first and then shook it up with magnesia oxide and magnesia carbonate and let it settle and decant and used it for washing purposes. I have not had any experience with the formula that is proposed for adoption, but I do know that you get a very nice preparation, a very smooth preparation, one that pours easily and stands up very well. You do have to wash a very long while and must be very, very careful that your magna never dries on cheese cloth."

S. L. HILTON:—"The preparation itself is a mechanical one pure and simple, and one that cannot be hurried in its manufacture; the best results I have been able to obtain is by sedimentation and not by straining; straining is liable to make the finished product more or less lumpy so that it will be impossible to obtain a smooth product. Further, the straining process may be satisfactory for a litre or two, but if you make a quantity of the preparation, for instance, forty gallons, how are you going to strain that amount of magna? It is impossible

to handle it in that way. Consequently, for large quantities, sedimentation is far better and I have also found that for small quantities it is equally satisfactory, more cleanly, and gives a better finished product. I use a much stronger solution of Magnesium Sulphate and solution of Sodium Hydroxide. I do not use hot solutions, as I have found by experiment they are not necessary. The condition of the magma formed, is in my judgment governed entirely by the way the solution of Sodium Hydroxide is added and the rapidity of agitation of the solutions at the time of mixing. The strength of the magma as obtained by the formula suggested, that is the amount of Magnesium Hydroxide in suspension, is insufficient, it is far less than the proprietary preparations for the reason that the solutions you start with are not strong enough. The Magma Magnesia obtained by this formula will assay only about five and a fraction *per cent.*, the proprietary will assay six *per cent.* The product I have been making will assay from six and one-half to six and three-quarters *per cent.*, and after assay I adjust same to six and one-half *per cent.*

"Unless water free from iron and organic matter, can be obtained it is necessary to use distilled water or the product will not be perfectly white, and some attention should be paid as to the amount of sulphate remaining in the finished product. It is not necessary to carry the washing to the point where all or practically all of the sulphate is removed; a certain definite amount of sulphate remaining in the finished magma has a decided advantage; it assists the laxative action of the preparation and, unless this be excessive, it does not have any unpleasant taste in the finished preparation. I have adopted a standard of my own on this point and every lot made is adjusted to contain a definite amount. I think this should be taken into consideration and provided for."

CHAIRMAN COOK:—"The next preparation is the magma bismuthi. The formula has not been an official formula in any of the standard books. This is now proposed for inclusion in the pharmacopœia. We have a number of criticisms of the formula.

"Dr. Francis can probably tell us something about this phase of the formula."

DR. J. M. FRANCIS:—"Because of limited time I did not intend to offer any suggestions, but as it has been requested by the chairman, I would say that my extensive experience in the manufacture of Milk of Magnesia and Milk of Bismuth warrants the statement that there are several details of the process which demand more careful consideration.

"In the case of Milk of Bismuth, containing the quantities of ingredients specified in the proposed formula, it is a fact beyond dispute that by varying the temperature and the several manipulative details, one can produce a Milk of Bismuth so dense, or in other words, so thick that it cannot be poured out of a bottle having an ordinary mouth, or, on the other hand, a magma can be produced consisting of such a coarse powder that an excessive proportion of water will separate on standing and the product will be wholly unfit for use. The same statement as to the possibility of varying the density of the magma is equally true in the production of Milk of Magnesia.

"I have taken occasion to criticise the formulas for both the Milk of Bismuth and the Milk of Magnesia, to the effect that the maximum quantity of water-soluble salts allowed to be present, is entirely too small. The chief item of expense in the preparation of both of these preparations, is the large volume of distilled or filtered water required for washing, or for the removal of the soluble salts produced by the chemical reaction. If this washing is extended, so as to greatly increase the volume of water necessary, the cost of the water will actually exceed the cost of the medicament employed. Certainly, the washing of the magma should be continued until only traces of the soluble salts remain, but a considerably greater quantity of the soluble sulphates or chlorides should be admitted than is proposed by the formulas which have been offered for adoption. What harm could possibly result either to the stability of the preparation or to the patient using the Milk of Magnesia or the Milk of Bismuth, by the presence of traces of soluble chlorides or sulphates?

"In this connection, it is also well to consider the great variation in the content of hydrated oxide of magnesia on the one hand and hydrated oxide of bismuth on the other, in the several preparations now very widely marketed by different firms. There should be some uniformity, and while the degree of concentration should be placed reasonably high, it should also be kept within the limits of economical production.

"Another fact brought out by Prof. Cook, in the previous discussion, is the question of indicating the value of these two preparations in terms which are comprehensible to the average physicians. While a statement to the effect that each ounce of Milk of Bismuth contains a given number of grains of hydrated oxide of Bismuth is scientifically correct, it means little to the average doctor. Physicians seldom or never prescribe the oxide of bismuth; this is not a commercial article. They are, however, entirely familiar with the dose of subnitrate of bismuth, and if we state that each dram or each ounce of milk of bismuth is equivalent to — grains of bismuth subnitrate, they can easily determine dosage.

"It should also not be forgotten that in the process of manufacturing, milk of bismuth should always be left distinctly acid in reaction, as otherwise it will shortly revert to the alkali or neutral state, and in this condition will rapidly discolor on exposure to light. Sometimes even a dark mirror of reduced bismuth will cover the entire inner surface of the bottle."

CHAIRMAN COOK:—"The next preparation is the solution of iron albuminate of the National Formulary. I will ask Prof. LaPierre his difficulty."

PROF. LAPIERRE:—"My difficulty was in reference to the addition of sodium citrate. I had no difficulty at all in the solution of albumen or in the addition of iron to the albumen. But at the time of the addition of the sodium citrate the precipitation of the iron occurred and it would not go again in solution notwithstanding all sorts of arrangements to coax it back into solution again. I tried it with a smaller quantity of sodium citrate with no better results. I am open to instruction along that line. I believe that is going to be the trouble with that preparation."

CHAIRMAN COOK:—"Anyone else have a suggestion to make in regard to this difficulty? I might say that the National Formulary Committee in preparing this formula have found it necessary to advise that the iron oxychloride be freshly made and used immediately."

PROF. LAPIERRE:—"I made the oxychloride fresh and we had no difficulties with that same iron in the preparation of peptonates."

CHAIRMAN COOK:—"The next preparation is one which has been causing discussion back and forth during the entire revision work of the pharmacopœia. There is the much mooted question of soft soap, one made from cotton-seed oil, the other from linseed oil. The subcommittees that have had this preparation in charge have unanimously agreed—probably I should not say unanimously—but the committees have all agreed to introduce the cotton seed oil soap. I personally believe it to be a great improvement over the other formula. We have here samples of the U. S. P. linseed oil soap and the proposed cotton seed oil soap.

"The chief objection to this formula is that the claim is made that it is not as detergent. Is there any discussion on this subject. I know that the cotton seed oil soap particularly has been used very extensively for a number of years by some larger users, and it has proven very satisfactory.

"If there is no discussion, the next preparation is compound solution of cresol, which has caused very much criticism. The present formula as now proposed for the pharmacopœia, calls for the saponification of linseed oil, making linseed oil soap, and the subsequent solution of that in cresol."

PROF. SCOVILLE:—"In other words, you will find that cresol is as good a solvent for soap as alcohol, if you dissolve your oil directly in the cresol and then add the alkali solution; saponification takes place in the cold, and that quickly. But you cannot use the preparation at once because you find that it clouds when diluted. It does not mix immediately. The difficulty there is that the saponification is not complete, although your solution looks perfectly clear. You can remedy that, if you choose, by heating it, but if you do that you darken your preparation. In order to get a light colored preparation it is necessary that you should let it stand."

CHAIRMAN COOK:—"The main argument in the committee against the use of directly dissolved soap, was that large variation was found in the soft soaps in the market and it was feared they would not be official soft soap. That led the committee to recommend the making of the soap. Again, I believe an inference would be permitted here, by the clause in the pharmacopœia to use a soft soap as a starting point, if we know the end point is all right."

MR. I. A. BECKER:—"I have had no complaint from the doctors, or in making a perfect preparation so far as its pharmaceutical preparation is concerned, by simply taking the cresol in equal weight to the soft soap and stirring it up and letting it stand twenty-four hours to thirty-six hours, when it readily dissolves. I might add that that thick solution readily goes through filter paper."

CHAIRMAN COOK:—"If there is no further discussion we will go to the next preparation, Glycerite of Bismuth.

"I have understood that Prof. Scoville has made a special study of this preparation, and we will be glad to hear what he has to say."

MR. W. L. SCOVILLE:—"The suggestion I made on the preparation, is that according to the present formula there is a loss of ten to twenty *per cent.* of your bismuth. Still, of course, it is an official preparation. The loss comes from the fact that in the very acid mixture that is first obtained,—not solution but mixture—after the bismuth is dissolved in nitric acid, we add tartaric acid, and then bicarbonate of soda, and we get a heavy precipitate of bismuth tartrate. That is supposed to carry down all the bismuth, but it does not. The solution is entirely too acid, and my modification simply calls for the addition of some bicarbonate of soda so as to throw down as much as possible of the bismuth. I have never been able to get it all down. The formula makes that loss within five *per cent.*, that was as close as I was able to make it. The formula, as submitted, would probably make nearer to 950 cc. instead of 1000."

CHAIRMAN COOK:—"Anyone else have anything to say with regard to this preparation of Glycerite of Bismuth? (No response.)

"The next preparation is the elixir of the phosphates of iron, quinine and strychnia. This preparation has received merited discussion *pro* and *con*. The formula which is proposed is one submitted by Mr. Beringer at the meeting of the New Jersey Pharmaceutical Association some time ago. There has been another formula proposed by Prof. Caspari, which is a modification of the one now official, which requires no neutralization. It is allowed to re-

main acid. But the chief objection to the formula of Mr. Beringer is the tendency to darken slightly. At temperatures such as we have here this morning, the preparation is a very beautiful one. It is made quickly. It does not vary quickly in color; it is recommended to be kept in amber colored bottles, but as soon as the temperature reaches that of ordinary fall weather, precipitation occurs in some instances.

"I have put it directly on the ice and you see the precipitation.

"The Caspari formula has the same precipitation. I have had them both on the ice. So we have the peculiar situation of having two formulas each having the same objection.

"Here is another of the Beringer formulas proposed, showing the precipitation. I will be glad to have some discussion on this point."

MR. W. L. SCOVILLE:—"There is no more delicate or troublesome formula in pharmacy today than that of the elixir of phosphates of iron, quinine and strychnia. It is a very easy thing to make a preparation that will look good for a week or two, or a month or two; it is another proposition to make one that will stand for a year or two, and stand changes of temperature and exposure.

"There are two or three things about that formula that I do not think are very much understood. One is the action of light on the ferric salt, particularly in the presence of citrates. So I ask, is it understood that light causes the decomposition of citrates by ferric salts? A normal citrate will entirely be decomposed by the ferric salt if it is exposed to the light. That is one reason why that elixir should never be put up in a white bottle, no matter what your formula is.

"Another difficulty is, that if you get in an organic acid in the presence of quinine, you have some of your quinine changed to a poisonous form, quinotoxin. It is the explanation of some disintegrations of quinine, perhaps,—troublesome reactions; illness after taking quinine. It occurs in the presence of quinine with organic acids. With mineral acids you are not likely to have any difficulty.

"One of the difficulties in the past, of course, has been the presence of sugar. You cannot put sugar in a preparation of that kind without it darkening. The new formula uses glycerin, which is a decided advantage.

"The action of light, the influence of quinine and the acidity, all have an important bearing on that preparation. I think I have made, without any exaggeration whatever, 200 tests of formulas for elixir of phosphates of iron, quinine and strychnia. The more I make the more I respect that preparation. It has got me guessing. I do not feel discouraged over it, however. I expect some day to have something that is really worth while. I do not know whether I have it now or not. It takes time to find out. The difficulty is, I cannot find out for a year and a half whether I have what I expect or not. I thought I had it six months ago, but some difficulties came up. I have some more standing. I have some standing in a wooden box outside my window. It is going to stand there all the time, through summer and winter. The only thing I exclude is the light. Any formula that would stand the light would not be a ferric solution; you might make a ferrous solution."

DR. WILBERT: "I believe an immense amount of time and money has been wasted on this preparation, and for no real good reason.

"A number of years ago Prof. Dichl introduced in the National Formulary his well known formula for elixir of pyrophosphate of iron, quinine and strychnia. This preparation is easily made, can in fact be thrown together, and will keep almost indefinitely without much change. I think we have devoted altogether too much time to the fetish that the ingredients must be present in the form of phosphates. The elixir of pyrophosphate is readily made and will stand fairly well."

MR. W. L. SCOVILLE: "I would like to call Mr. Wilbert's attention to the sample of elixir of pyrophosphate of iron, quinine and strychnia on the case there."

CHAIRMAN COOK: "Any further suggestions about this preparation? I would be very glad to have the help of the members."

"All the criticisms, I hope you understand will be very carefully noted and referred immediately to the committee on revision.

"The next preparation is the new aromatic fluid glycerate of cascara sagrada. I have three samples here. This is a new preparation and is here for your observation.

"The next preparation is the tincture of ferri citro-chloridi of the National Formulary, the basis of the making of elixir iron, quinine and strychnia without the phosphate. There was considerable criticism of the formula. It will be referred to the committee on revision."

MR. WM. A. HART: "Having had this work in hand I did not expect any particular trouble, but I was particular in getting a solution of chloride of iron for my base that was exactly U. S. P. and with a gravity of 1.310. Using that as the basis, taking the requisite quantity of sodium citrate called for, 125 grammes, I found I did not have a green but a brown solution. Of course, I knew I did not have enough sodium citrate. I kept on adding until I had added 100 grammes, making 525 grammes, to make the reaction complete as shown by the emerald green color. Then I took another sample of solution of iron, which had a gravity of the 1890 U. S. P., namely, 1.290, and found 125 grammes sodium citrate was practically enough. I added 20 grammes more, but the little difference might be simply the little variation in reading the gravity. I would not criticize it on that score. But with the

specific gravity of 1.310 it certainly required more sodium citrate. Then I began looking it up and sent the memoranda of the details to our Chairman for action before the National Formulary Committee.

"With the gravity of a solution of iron of the last pharmacopœia, the trouble is that we have increased the gravity or the strength of the solution of iron in the present pharmacopœia beyond that of the last and we have not changed the quantity of sodium citrate. That is the whole substance of it. So that it would seem as though it will have to be threshed out a little more; that the sodium citrate will have to be increased."

MR. F. M. APPLE:—"That was my experience in making up the preparation."

CHAIRMAN COOK:—"The next preparation is a new preparation for the National Formulary, a compound solution of phosphates. This preparation was made with the intention that it would form a stable concentrated solution for the making of a number of other preparations which call for phosphates; notably the syrup of phosphates.

"I have samples here made over a year, and one made more recently, and quite extensive criticism of this formula by Mr. Hensel of Denver, together with criticism from Dr. Englehardt of Baltimore. The criticisms will be referred to the National Formulary Committee. Has anyone anything to say about it?

"If not, the next preparation is the syrup made from this solution, which is also here for you to see, showing quite a striking difference in the two preparations made by the two men.

"The next preparation is the tincture of cudbear of the National Formulary. This preparation has been the cause of probably more discussion in the National Formulary Committee than any other one preparation. The preparations are here before you with some notes with regard to difficulty in percolation, which has been the old story in regard to this preparation.

"The next preparation is an antiseptic solution of pepsin. This preparation received considerable comment when it was published in the Journal a number of years ago. It is a stimulating antiseptic wash for wounds, I believe."

DR. WILBERT:—"There is nothing to say except that it is a wash used for cleaning and flushing wounds. It has been used extensively in surgical practice and with satisfaction. We have made it at the hospital for a number of years and it has been used there and in other places. It is not intended at all for internal use."

MR. EDELL A. RUDDIMAN:—"What effect has the antiseptics on the action of pepsin? Do they interfere there with the digestive action of pepsin?"

DR. WILBERT:—"Possibly they do, but we make the preparation up fresh. It is never kept more than a couple of months. The loss in activity is not material and we have never had any complaint from it, at least not in my time."

CHAIRMAN COOK:—"The next preparation is the syrup of hydriodic acid. The formula is here rather for you to see than to comment upon specially. I might say that glycerin has been omitted in the preparation of syrup of hydriodic acid. This was originally proposed but found to be objectionable. The formula is modified to this extent. This is practically the same as the present U. S. P. excepting that the amount of hydriodic acid is slightly increased so that instead of one *per cent.* I think we will have about 1.25 *per cent.* present. It is also made up instead of by weight, by mixing volumes.

"The next preparation that I have on my list is solution of magnesia citrate. Unfortunately, the sample was broken in transportation. I have had a number of criticisms. Anyone who would like to say anything about the newly proposed formula for solution of magnesia citrate?

"If there is no discussion, the next preparation will be elixir of phosphorus. The preparations you have before you. The old criticism that has come in, is that they prefer the old method. The formula itself is probably satisfactory.

"That concludes the preparations that I had specifically selected in filling out the program as I had planned it.

"I would now ask for the reading of the paper on zinc oxide ointment by Mr. Ernest R. Jones."

## A NEEDED CHANGE IN OINTMENT ZINC OXIDE, U. S. P.

ERNEST R. JONES, PH. C.

It is a well-known fact that this ointment, after standing for a little while, becomes very granular and is anything but a sample of pharmaceutical elegance.

Most of the previous papers on this subject have ascribed the cause as due to the zinc oxide or to faulty compounding of the formula, and have suggested changes in the manipulation of the present formula which were expected to produce a permanently smooth ointment.

Some have advocated rubbing the zinc oxide until thoroughly smooth with a small quantity of a fixed oil, such as castor, olive or cottonseed oil; then incorporating the lard. Others have tried the expedient of first bolting the zinc oxide very finely. Another endeavored to accomplish the same purpose by a process of elutriating the zinc oxide.

It is very doubtful if any of these persons have kept their product under observation during a sufficient length of time, say perhaps a year, in order that it could have encountered the different changes in temperature. I have tried all of the different suggestions, but have not as yet found any that solved the difficulties. I recently had an opportunity to observe a one-pound sample of U. S. P. ointment which had been made according to one of these new schemes of manipulation and which, after setting undisturbed on the shelf for over a year, was apparently as good as when made. It seemed to have solved the difficulty, until upon digging down toward the bottom of it, we found that the lower portion was soft, granular, and almost semi-liquid, whereas the top portion was smooth and hard. This would indicate that a separation of the constituents of the lard had taken place.

The writer once had an idea that possibly enough saponification took place between the free acids of the lard and the zinc oxide to liberate enough water to cause the trouble. There is no doubt that some zinc compounds are formed with the acids, for they may be separated with ether. Careful estimation of the amount of water present in the ingredients before making them into the ointment, and estimations of the amount present in the ointment after standing six months, showed that this reaction does not take place to a degree sufficient to cause the granulation.

With a view to determining whether the granulation was caused by the zinc oxide not being in a fine enough state of division, my co-worker, Mr. French, made up a sample following the U. S. P. directions carefully, and then passed it through an ointment mill ten times. Surely the zinc oxide must have been fine enough after this treatment to eliminate any cause for trouble in this respect. However, after a short while it was just as granular as the others.

You gentlemen are all familiar with the composition of lard and know that its constituents vary considerably in physical characteristics. The glyceride of oleic acid is a liquid, while those of palmitic and stearic are solids. If you will examine good lard under a low power microscope, you will observe that it has a very "seedy" appearance, indicating that it is not entirely a homogenous mixture of the combined glycerides. As a warmer temperature is attained, my opinion is that the olein, on account of its liquid nature has a tendency to separate and that upon cooling again without stirring, the stearin and palmitin being more solid, is partly separated in such a manner as to cause the granular appearance.

I have here for your inspection, a sample of benzoinated lard which, four months ago, was as nice a product as one could desire. Granular lumps are now perceptible to the naked eye. This is strong proof that the cause of the trouble is not due to the zinc oxide, but rather to the lard.

My conclusion is then, that just as long as we continue to use benzoinated lard for a base, we must continue to expect trouble from this ointment.

That the lard is the cause of the granulation can be proved by substituting

petrolatum in its place. Such an ointment will remain smooth for an indefinite period. I have here a sample that is nearly one year old, and is perfect in appearance.

It is not my purpose to suggest another method for manipulating the present formula so as to make a permanently smooth ointment, for because of the peculiar composition of the lard, which was previously explained, I do not believe it can be done.

I sincerely believe, however, that the next edition of the U. S. P. should replace the benzoinated lard with a petrolatum base. This idea is not original with the writer. The Swiss and French Pharmacopœias use a base of white petrolatum, thus proving that two countries are aware of its superiority. Several manufacturing houses have, during the past few years, made a special ointment with a petrolatum base, in addition to the regular U. S. P. product.

The question may be raised that lard is better absorbed by the skin than is petrolatum, and according to some recent research reports it is quite likely that it is. Cushny says that "emollient preparations promote the absorption by the skin of drugs dissolved in them because the fat mixes readily with the thin layer of oily sebaceous matter which covers the skin." Inasmuch as the zinc oxide is not dissolved in the lard, the difference in absorption value between lard and petrolatum is of little value in this case. Just how zinc oxide ointment acts when applied to the skin, is hard to determine. Some claim it to be merely soothing. If so, would not the result be just as satisfactory without the zinc oxide? Others claim it to be healing because of its astringency. This seems quite probable, and Cushny says the astringency of zinc compounds is due to their forming insoluble albuminates. This is purely, then, a local action and in my opinion should take place from a petrolatum base as well as from lard.

If the choice of base has no advantage from a therapeutic standpoint, but has from the pharmaceutical, why should we not make a change in its formula?

The simplest formula would consist of 20% of zinc oxide and 80% white petrolatum. This makes a fine product, but is quite a bit softer than we are accustomed to see it and would therefore alter the consistency of every other established preparation which it enters into. The following formula, which is hardened with white wax gives a product resembling the consistency of the present ointment.

Zinc Oxide .....	200 Gm.
White Wax .....	150 Gm.
White Petrolatum .....	650 Gm.

Rub the zinc oxide, which must be free from gritty particles, with an equal weight of melted white petrolatum until smooth and add to this the remainder of the white petrolatum which has been previously melted with the white wax. Strain the ointment while warm and stir thoroughly until it congeals.

One more point of interest, is that the U. S. P. ointment is stronger than that of any other Pharmacopœia. Those of the Swiss, Spanish, Japanese, French, Netherlands and German Pharmacopœia contain 10% of zinc oxide; the Austrian and British, 15%; and finally the U. S. P. which stands alone with 20%. I believe that 10% of zinc oxide is quite sufficient, inasmuch as it is probably not absorbed by the skin, and the extra 10% is wasted.

These suggestions are presented, not as representing any new discovery, but with an idea of trying to convince the Revision Committee that the time has arrived to change the base of this ointment and avoid inflicting another ten years of hardship on the pharmacist.

The white petrolatum base makes a smooth, white ointment which does not granulate or turn rancid. Why not adopt it in the next U. S. P.?

#### DISCUSSION.

MR. STOLZ:—"That paper appeals to me, and I thank the gentleman for having written such a beautiful paper, because I think zinc ointment is a very serious question with a great many of us.

"A number of the manufacturing houses put up zinc oxide ointment and we buy it in twenty-five and fifty pound lots. We happened to get in a jar from Squibb & Son and when we had used about ten pounds of it it became granulated. We took it up with the representative and he simply told me 'Mr. Stolz, we make our ointment U. S. P. with benzoated lard. We hear that complaint all over.'

"I would like to ask Mr. Cook if they have done anything in the new Pharmacopoeia toward changing the base."

CHAIRMAN COOK:—"The formula is to be retained."

MR. GRAY:—"I have been serving the leading physicians of Chicago in a hospital for eight years, and we have used nothing but the vaseline base for zinc ointment."

MR. J. A. BECKER:—"My house also furnishes a zinc oxide ointment with vaseline base."

DR. WILBERT:—"We have been using it for twenty-five years,—so long as this is an experience meeting."

MR. STOLZ:—"You will find ninety *per cent.* of manufacturing houses sending out zinc oxide ointment with petrolatum base."

MR. E. R. SELZER:—"I move that this section recommend to the Revision Committee the adoption of petrolatum as a vehicle instead of benzoated lard."

MR. WILBERT:—"I second the motion."

CHAIRMAN COOK:—"The motion before the house is that it is the sense of this section or at least it is recommended by this section that the Revision Committee adopt petrolatum instead of benzoated lard in zinc oxide ointment."

Motion duly carried.

MR. L. C. HOFF:—"I think the great trouble with zinc oxide ointment is that the benzoated lard becomes slightly rancid, and you can overcome that to a certain extent by using a little alkali mixing it with your lard. I tried that and it worked out all right. We have doctors who insist that lard be used in their preparations, and one man in particular, when he is prescribing zinc oxide ointment and don't know where the prescription will be put up, specifies 'This shall be made up with benzoated lard.'"

MR. GRAY:—"I would suggest, if it is in order, that we classify our ointment absorbent and non-absorbent. I believe some pharmacopoeias do that."

MR. JONES:—"I anticipated some argument on this question and I would like to say I have worked on some experiments to see if we could not use a mixed base of benzoated lard and petrolatum, and I found I could use twenty-five *per cent.* of lard and still make quite a good ointment, but the experiment has not been standing long enough to warrant me in incorporating it in the paper. They have been standing about six months and look very good."

MR. W. F. JACKMAN:—"This is one point I do not think we have considered, a number of our citizens in the United States object to the hog on religious grounds as well as sanitary grounds, and to meet such a situation one-fourth wool fat and three-fourths petrolatum I think is fully equivalent to the formula under discussion."

CHAIRMAN COOK:—"The next order of business on the program is the election of officers, but as explained to the section on Tuesday, the Council have directed or have arranged in their own minds that this section be discontinued as a section. It becomes a special committee of the Practical Pharmacy section. The chairman of that special committee is to be appointed by the Section of Practical Pharmacy."

"All the other set features having been taken care of, I will offer the opportunity at this time, it is just twenty minutes to twelve, and the automobile ride, I believe, is at 2:30—I will allow any time now to the consideration of any one of these preparations before you, which you may be specifically interested in. We will get the samples out here and give you an opportunity to tell briefly, if possible, any difficulty you may have, so these criticisms may go before the committee. All the criticisms that have come in will be before the committee."

DR. WILBERT:—"Before the members leave the room, and in view of the fact that this is the last session of this particular section, I would like to move a vote of thanks to the Chairman for the excellent work he has done in connection with this particular section. I think his getting together this exhibition is an object lesson that may well be appreciated, and the only unfortunate thing is that more men in the retail business have not been able to see it

or have not taken time to look at the various preparations of the exhibit and profit by the possible short-comings that have been evidenced thereby.

"I would move, Mr. Secretary, that a rising vote of thanks be extended to the Chairm for the excellent work he has done in this section."

SECRETARY THUM:—"A motion has been made and seconded that a vote of thanks be extended to Chairman Cook for the excellent work he has performed in this section. All in favor of this motion will please rise."

(Unanimously carried.)

CHAIRMAN COOK:—"Thank you, gentlemen. I am sure that the success of this section has depended upon the splendid coöperation of about fifty members of the A. Ph. A., and thanks are due them.

"If there is no special preparation you wish to discuss, a motion to adjourn will be in order."

DR. WILBERT:—"I make the motion, Mr. Chairman."

Motion carried.

---

### HIGH EXPLOSIVES IN WARFARE.

The high explosives being used for artillery shells in the war constitute the subject of an interesting article in *Nature*. For military purposes explosives of the nitro-glycerin class and many others are excluded, because the military high explosive must be sufficiently insensitive to shock to prevent its being exploded when struck by projectiles or when submitted to the shock of being fired from a gun as the charge of shell. Gun-cotton, containing a considerable amount of moisture, was formerly used for many years. This provided an excellent and safe explosive for military mines and purposes of destruction and as a charge for torpedoes, but was not suited for use in shells. The high explosives chiefly being used for shell-firing at present are picric acid, trinitrotoluol, and ammonal. Picric acid, which superseded black gunpowder, has been in use in most countries under the names of melinite, lyddite, shimose powder, etc. But, although sufficiently insensitive to shock, it has the disadvantage of readily attacking metals and forming picrates, which are much more sensitive and liable to explosion. Ammonal is a mixture of ammonium nitrate, trinitrotoluol, charcoal, and aluminum in fine powder. It is safer and more powerful than picric acid, but needs to be very carefully guarded from moisture on account of the hygroscopic character of ammonium nitrate. Trinitrotoluol, known under the names of Trotyl, Tritolo, Tolite, Tritol, Trilite, and T.N.T., is the most widely used military high explosive. It is less sensitive to shock than picric acid, is chemically stable and unaffected by water and metals, and can be fused and run into shells in the molten state. Hard blocks of suitable size and shape are covered by electroplating them with copper, to prevent their being broken or chipped. The destructive effect of an explosion is caused by the almost instantaneous conversion of the solid explosive into gases at a very high temperature, with the consequent sudden exertion of an enormous pressure. In addition, where the explosion takes place in a closed space, the resulting gases, especially carbon dioxide, may have poisonous effects on anyone having to breathe them.

## Scientific Section

Papers Presented at the Sixty-Second Annual Convention

### MORPHINE NITRATE AND MORPHINE ACETATE.\*

H. ENGELHARDT AND O. E. WINTERS.

The variation in purity of commercial morphine nitrate and morphine acetate is very marked, as we have found in our experiments on numerous samples of the salts. In order to find out the extent of such variations the following experiments were undertaken with five samples of the salts, manufactured by different firms and purchased on the open market. The samples were marked I-II-III-IV-V and the methods applied for estimating the purity were the following:

*I. Process similar to the U. S. P. method for estimating morphine in opium:*—.85 gm. of the morphine salt is dissolved in 15cc. of water, and the solution is mixed with 7.5cc. of alcohol, 15cc. of ether and 2.2cc. of ammonia water. The mixture is then shaken for ten minutes and allowed to stand over night. The crystallized morphine is collected on a filter, washed with etherized water and dried at 60° to constant weight.

*II. Puckner's Method:*—(*Journ. Amer. Med. Assn., Sept. 13, 1913*)—.5 gm. of the morphine salt is dissolved in 20cc. of water and mixed with 0.25cc. of ammonia water, the mixture is shaken for five minutes and allowed to stand over night. The morphine is collected on a filter, washed with morphinated water, dried at 60° to a constant weight. To the amount of morphine found .0076 gms. is added, the amount of morphine soluble in the aqueous liquid.

*III. Nitron Method:*—.35 gms. of the morphine salt is dissolved in 50cc. of water and mixed with about 5cc. of a 10 *per cent.* solution of nitron in 5 *per cent.* acetic acid. After allowing the mixture to stand in a refrigerator for two to three hours it is filtered through a Gooch crucible and the precipitate is washed with ice water (using not more than 10cc. of the latter) and dried to constant weight. The weight multiplied by .93 gives the amount of morphine nitrate, according to the equation:—

*IV. Schafer Method.* (*Amer. Journ. Pharm., 1913, page 139.*)—.85 gm. of the morphine salt is finely triturated in a small mortar with a sufficient quantity of purified sand and an excess of sodium bicarbonate. The mass is moistened with a little water and allowed to dry again at a temperature not exceeding 30° to 40°. The mixture is then transferred to an Erlenmeyer flask, and to the con-

\* Scientific Section at Detroit.

tents of the flask a freshly prepared mixture, consisting of one volume of methyl alcohol and four volumes of chloroform is added, and the mortar is carefully rinsed with the same liquid. The mixture is allowed to stand for one hour with moderate but frequent shaking. The liquid is then filtered through a small filter and the residue washed thoroughly with three to four portions of about 10cc. each of the above solvent. The combined filtrate and wash-liquids are distilled off, the residue taken up with an excess of N/20 sulphuric acid and the excess of the acid titrated in the usual way using cochineal or methyl red as indicator.

*V. a. Isobutyl alcohol-chloroform method.*—5 gm. of the morphine salt is dissolved in 20cc. of water, the mixture made alkaline with sodium bicarbonate and shaken out with 50cc. of a mixture of equal parts of isobutyl alcohol-chloroform. The chloroformic solution is drawn into another separator and the aqueous solution shaken out twice more with each 30cc. of the above chloroform-isobutyl alcohol mixture. The combined alcohol-chloroform solutions are shaken out once with water in order to remove any suspended alkali and are then shaken out with 20cc. of tenth-normal sulphuric acid, followed by two portions of 20cc. each of water. The combined aqueous solutions are then titrated with standardized alkali in the usual way.

*V. b.* As an alternative process 0.5 gm. of the morphine salt was dissolved in 20cc. of water, the aqueous solution made faintly alkaline with ammonia and then shaken out as just given with various portions of a mixture of isobutyl alcohol-chloroform. The combined alcohol-chloroform solutions were then evaporated in a vacuum and the residue titrated in the usual way.

*VI. Vanderkleed Method:*—(*Journ. Amer. Pharm. Assn., Aug., 1913.*)—A solution of the morphine salt equivalent to about .2 gm. of morphine is dissolved in 15 cc. of water in a separator, the solution mixed with amyl alcohol, made alkaline with the ammonia water and heated on a steam-bath at 80° for about five minutes. The mixture is then shaken for about two minutes and, after allowing to cool, the aqueous layer is drawn off into a second separator and the amyl alcohol transferred into a 300 cc. Erlenmeyer flask. The aqueous solution is extracted twice more with amyl alcohol in the same way. The combined amyl-alcoholic solutions are evaporated in an oil-bath to dryness. (We have found evaporating solution in a vacuum gives better results.) The residue is dissolved in 20 cc. of N/20 sulphuric acid and the excess of acid is titrated back with N/20 potassium hydroxide solution, using methyl red as indicator.

*VII. Buchbinder Method:*—3 gm. of the morphine salt is dissolved in 30 cc. of lime water; to the solution .5 gm. of ammonia chloride is added and 30 cc. of a mixture consisting of two parts of chloroform and one part of alcohol by volume. After shaking the mixture well, the chloroform-alcohol solution is drawn off into another separator and the aqueous solution shaken out with various portions of the chloroform until the latter no longer takes up morphine. (We have found that even by extracting the aqueous solution ten times with chloroform not all the morphine is removed, but that only about three shakings are necessary, when chloroform containing about 10 per cent. of alcohol is used for the extraction.) The combined chloroform-alcohol solutions are evaporated to dryness, the residue is dissolved in 10 cc. of neutral alcohol and a convenient excess of N/50 sul-

phuric acid is added. The alcohol is then evaporated and the acid solution titrated with N/50 potassium hydroxide, using either cochineal or methyl red as indicator. The results given below were obtained by using a chloroform-alcohol mixture throughout.

In order to determine the accuracy of these methods we applied them to pure morphine, which had been obtained by recrystallizing the alkaloid several times from the alcohol. When titrated the alkaloid showed a purity of 100.0 *per cent.* and 99.7 *per cent.*

The results obtained with pure morphine, the samples of morphine nitrate and morphine acetate are given in the following table:—

PURE MORPHINE								
	U. S. P. Process	Puckner Method	Nitron Method	Schafer Method	Isobutyl alcohol- chloroform Method		Amyl alcohol Method	Modified Buch- binder Method
		96.6%		100.3%	98.2%		98.6%	98.7%
		97.6		102.5				98.2
MORPHINE NITRATE.								
I.	85.9%	87.9	87.1	97.4 95.7	84.8	88.04*	86.4*	83.5
II.	88.0	86.5	87.2	90.8 93.6	82.9	88.5*	85.2*	86.6
III.	90.7	88.7	90.9	92.2 92.2	88.0	86.8*	83.4*	86.7
IV.	87.8	89.9	89.6	92.6 93.2	89.7	84.7*	86.3*	86.4
V.	87.0	88.5	89.3	90.8 94.5	87.5	85.8*	84.2*	86.3
MORPHINE ACETATE.								
I.	95.46	93.5		121	99.8		101.3*	96.8
II.	90.63	86.8		108	97.8		98.1*	92.2
III.	92.19	93.5		112	93.8		97.7*	93.8
IV.	93.08	92.6		113	93.8		97.2*	95.7
V.	91.41	88.0		117	97.0		98.4*	94.3

\* These results were obtained by evaporating the solutions of the morphine in the immiscible solution to dryness in a vacuum.

From these experiments it is evident that the purity of morphine nitrate rarely is above 90 *per cent.* and that the purity of morphine acetate is also far below 100 *per cent.* The latter is the more surprising as every sample exhibited a strong odor of acetic acid. If there is a loss of acetic acid, the percentage of morphine in the sample should be above 100 *per cent.*, provided the sample originally showed this purity.

In view of these facts it would be advisable for the Sub Committee on Organic Chemicals of the Revision Committee of the U. S. P. to take this matter up, give requirements for a certain purity of these salts and furnish at the same time a reliable assay process.

By all the methods given in this paper the total alkaloids present in the morphine salts are determined. It is a well-known fact, that morphine sulphate and

most of the other morphine salts contain a considerably large amount of other opium alkaloids. These by-alkaloids should be determined also, inasmuch as they are ether-soluble and may seriously interfere with the estimation of morphine in mixtures with other ether-soluble alkaloids such as atropine, etc. This can easily be done by the isobutyl alcohol-chloroform method, as has been shown by one of us a short time ago.—(*Deutsch-Amerikanische Apotheker Zeitung*, Jan., 1913.)

## THE COMPOSITION AND ASSAY OF HEROIN HYDROCHLORIDE AND DIACETYL-MORPHINE HYDROCHLORIDE.\*

---

R. T. HARRIS AND A. M. CLOVER.

---

Upon assaying certain preparations containing heroin hydrochloride, it was found that the amount of alkaloid was about 5% less than that supposed to be present, and upon going further into this matter it was shown that the direct assay of heroin hydrochloride, by the same method, gave a similar result. The method of assay was then tested upon the base, heroin, and upon diacetyl-morphine which had been purified by recrystallization and the result of these tests showed that the method was entirely reliable. Heroin hydrochloride is referred to in the literature in all cases which we could discover, as the anhydrous salt of diacetyl-morphine, this being the formula assigned to the product by its manufacturers. A like state of affairs exists in regard to the hydrochloride of diacetyl-morphine, but on the contrary we find that heroin hydrochloride contains 1 molecule of water. Two samples of diacetyl-morphine hydrochloride, obtained from different manufacturers, were found to have the same composition, while another sample from a third source consisted of the anhydrous salt. On account of the close scrutiny to which pharmaceutical products are frequently subjected nowadays it is well to clear up such confusion by careful experiments and to call attention to the existing facts.

*Heroin Hydrochloride*.:—When heroin hydrochloride is heated at 100° there is a decided loss in weight. Quantitative experiments are difficult to carry out owing to the readiness with which the resulting product absorbs moisture from the atmosphere; however, the loss in weight is no more than that resulting from the loss of 1 molecule of water. The substance is not changed in any of its essential characteristics and dissolves completely in water after heating. When the heated product is allowed to stand in the air for a few hours its weight reverts to exactly the original value.

Ten grams of heroin hydrochloride were dissolved in about 150 cc. water and precipitated carefully with diluted ammonia, until a slight excess of the latter had been used. The crystalline precipitate was filtered upon a Büchner funnel, washed free from ammonium chloride and dried. The combined filtrate was shaken out twice with a little chloroform and the latter solution evaporated until the solvent had been completely removed. The crystalline precipitate amounted

---

\* Read at Scientific Section, Detroit.

to 8.4 grams to which is to be added .1 gm. extracted with chloroform. The theoretical amount required for the anhydrous salt is 9.10 gms.

The above experiment was repeated with another sample of heroin hydrochloride which melted at 225-230° (uncor.). From 10 grams there were obtained 8.55 grams of heroin which melted at 169°-170° (uncor.) and .15 grams were extracted with chloroform.

Five grams of heroin melting at 169°-171° (uncor.) were dissolved in dilute hydrochloric acid, just enough acid being used to effect solution, the volume being about 125 cc. The solution was then precipitated carefully with ammonia and the precipitate and extract obtained exactly as from the hydrochloride. The dry precipitate amounted to 4.88 gms. while the extract yielded .1 gm. additional. There had been practically no loss.

1.53 gms. heroin were treated on a watch-glass with about .4 cc. of concentrated hydrochloric acid and stirred quickly. The heroin goes into solution completely and this is soon followed by a separation of the hydrochloride. The product was placed in vacuum to remove water and a slight excess of hydrochloric acid. When dry, it was pulverized and again placed in vacuum until a constant weight had been shown which was 1.77 gms. This is slightly in excess of that required for a hydrochloride containing 1 molecule of water.

*Diacetyl-Morphine Hydrochloride*:—This substance was prepared by the action of acetic anhydride on morphine and was purified by repeated crystallization from benzol until there was no further change in the melting-point which was 170°-171° (uncor.).

Eight grams of pure diacetyl-morphine were dissolved in a slight excess of dilute hydrochloric acid, and then precipitated with ammonia in the same manner as has already been described under heroin hydrochloride. The dried precipitate amounted to 7.88 grams.

A quantity of pure diacetyl-morphine was dissolved in about seven times its weight of dry benzol and treated with the calculated quantity of a saturated solution of hydrochloric acid in absolute alcohol. After standing one-half hour a large proportion of anhydrous diacetyl-morphine hydrochloride crystallized out. The crystals were filtered upon a Büchner funnel, washed with water-free benzol and dried. They melted at 131°-135°, which is considerably higher than the melting-point of heroin hydrochloride. This product did not show any loss in weight when it was heated at 100°. It lay in the air for several days without change in weight, but when a portion of it was powdered, there was a small increase of weight during the first twenty-four hours, followed by a rapid absorption of water sufficient in amount to correspond to one molecule. Nine grams of this salt were precipitated with ammonia in the usual manner and there were obtained 8.02 grams of precipitate and .11 grams of extract. The theoretical amount required for the anhydrous salt is 8.19 grams.

One and five-tenths grams pure diacetyl-morphine were treated on a watch-glass with a slight excess of 15% hydrochloric acid. The resulting product was freed from water in vacuum, powdered with a glass rod and then again placed in vacuum until a constant weight was obtained. The increase in weight was .2216 grams, while the mon-hydrated salt requires theoretically an increase of .2220

grams. The salt produced in this manner melts lower than the anhydrous salt and also lower than heroin hydrochloride.  $218^{\circ}$ - $224^{\circ}$  (uncor.).

Three samples of commercial diacetyl-morphine hydrochloride obtained from different manufacturers were examined. (1) The sample melted at  $230^{\circ}$ - $238^{\circ}$  (uncor.). Ten grams gave 8.91 grams of precipitated alkaloid and .11 grams extracted. 9.02 grams were recovered while the theoretical for the anhydrous salt is 9.10 grams. The product was therefore the anhydrous salt. (2) The sample melted at  $224^{\circ}$ - $228^{\circ}$  (uncor.). From 10 grams there were obtained 8.6 grams of precipitate and .12 grams of extract. The product is therefore the monohydrated salt. (3) The sample melted at  $225^{\circ}$ - $230^{\circ}$  (uncor.) and showed a decided loss in weight when treated at  $100^{\circ}$ . It is therefore the monohydrated salt.

Since the completion of these experiments our attention has been called to a statement by Schaefer (*American Journal of Pharmacy*, 82, 220), that only the monohydrated salt can be found on the market. He found that this salt when dehydrated, regains its water quickly from the air, but we have shown that this is not true of the anhydrous salt which separates from solution.

*Assay*.—Heroin or diacetyl-morphine may be accurately estimated by dissolving in excess of 1/10 normal hydrochloric acid and titrating the excess of acid with 1/50 normal sodium hydroxide using cochineal as an indicator.

	Weighed Sample.	Found.	Found Per Cent.
Pure diacetyl-morphine.....	{ .1362 grams	.1354	99.42
	{ .1735 grams	.1725	99.44
Heroin.....	{ .1323 grams	.1317	99.53
	{ .1336 grams	.1328	99.41

For the estimation of the alkaloid in its salts the following method is recommended:—An amount of the preparation representing at least one-tenth gram of the alkaloid and contained in 10 cc. of solution is treated with 20 cc. chloroform and sufficient 10 *per cent.* ammonia to render it slightly alkaline. After shaking vigorously, the chloroform is drawn off into a container suitable for titrating. The extraction with chloroform is repeated three times, after which the combined chloroform extract is evaporated. Add 5 cc. of 1/10 normal hydrochloric acid or sufficient to completely dissolve the alkaloidal residue then add a few drops of cochineal solution and titrate the excess of acid with 1/50 normal sodium hydroxide. The results obtained are very close to the theoretical.

*Scientific Laboratory of Parke, Davis & Co.*

## THE GLANDS OF INTERNAL SECRETION AND THEIR IMPORTANCE AS THERAPEUTIC AGENTS.

---

CAREY PRATT MCCORD.

---

The animal body, it appears, manufactures its own drugs. These drugs are the derivatives of the glands of internal secretion. These substances elaborated by the secretory cells of these glands are discharged into the circulation and carried to the various parts of the body. There they react upon the tissues in a manner for the well-being of the body as a whole.

The glands of internal secretion regulate and correlate some of the body's most important physiologic functions and constitute efficient protective and defensive measures against disease. There are, influenced by the glands of internal secretion, such functions as ovulation, pregnancy, muscle tonus, vaso tonus, secondary sexual development, adiposity, skeletal growth, sugar metabolism—on through an extended list. Despite the complexity and intricacy of these manifold manifestations of internal secretory activity the balance is maintained, in health,—in perfect harmony,—that is, the glands regulate and control each other. This interrelation, and interdependence of the glands of internal secretion have given rise to the term "internal secretory balance." Although these several glands are situated in the body widely apart from each other and have no visible connections one with the other, they constitute a unified system of glands, every individual of which having its function or functions, but contributing to the maintenance of a complex interrelation within the entire system. It is now established that there exists not only an organic and functional harmony between all glands but a compensatory interaction as well. Every gland acts, in its peculiar functional manner, upon the blood passing through its tissues, often adding to it bodies of vital importance to the welfare of the individual. If any organic disease or abnormality exists in a particular gland, the missing or altered function appears in some cases to be taken over by some other gland, and disaster is prevented. In other cases the altered metabolism of one gland upsets the normal metabolism of all the others and leads to its impairment and the impairment of the body as a whole. In its deepest significance, it is probable that every cell in the body is a potential ductless gland and has some slight influence on the life and functions of its fellow cells. The terms "ductless gland," "gland of internal secretion" and "endocrinous gland," are, however, restricted to these organs showing glandular tissue and yet having no ducts for discharging the formulated substances.

The tissues producing internal secretions are, pituitary, pineal, thyroid, thymus, parathyroid, pancreas, adrenal, ovaries, testes. There are, in addition, some indications of internal secretion from the tonsils, placenta, and carotid gland.

*Glands of Internal Secretion and Disease:*—While the ductless glands functionate for the maintenance of the normality of the body, they themselves are subject to disease and traumatism. In many instances, apparently as a prevention against traumatism, the ductless glands are so located that the very shielded and privileged situation of these organs suggests a vital importance. The pituitary gland resting in the saddle of the *sella turcica* of the sphenoid bone at the center of the skull is the best protected organ of the body. Scarcely less protected is the pineal gland near the center of the brain, the parathyroids embedded in and behind the thyroid gland deep in the neck, or the adrenals padded in the fat above the kidney. The removal of the glands experimentally, by accident, or through necessary operative procedures, manifests the absence of the gland by distressing and even fatal symptoms. The removal of the adrenals, for example, leads rapidly to the death of the animal or patient with great prostration and depletion before death due to the loss of the adrenal function of maintaining muscle and vascular tonus. The removal of the parathyroids leads to death from the accumulation of toxic bodies in the circulation, the destroying of which is

the parathyroid's function. The removal of the pancreas leads to diabetes and later to death. Not all glands, however, are immediately essential to life. In adult life the testes, ovaries or pineal gland may be removed without producing any fatal results.

It is not necessary that there be a visible anatomical destruction of the ductless gland to produce a perversion of its secretion and thus a disturbance of the body's equilibrium. They are subject to tuberculosis, to cancer, to infectious diseases, that may lead to a slight or grave impairment, which may manifest itself as an increased or a decreased function. Increased function of the pituitary gland leads to gigantism, acromegaly, while decreased function produces obesity. Increased function of the thyroid causes goitre, while decreased function causes the coarse featured obese cases called "myxoedema," and in young children is termed "cretinism." Even so mild a condition as the so-called "spring fever" may be a condition of decreased adrenal function. All considered, it is very evident that malfunction of these glands may produce very severe pathological states of the body, and it becomes a pertinent matter to inquire as to the efficacy of treating such conditions with preparations of glands derived from cattle, sheep or other animals.

*Ductless Glands as Therapeutic Agents:*—The conception of using animal derivatives in treatment is by no means new. As early as 6000 B. C. preparations from testes were given in the treatment of obesity. At about the same time there are also mentioned the use of such other animal substances as "swine's fat, dog's dung, fat of a serpent, hair of a virgin goat, and human bone." It is only a step from this, to our present-day desiccated *corpus luteum* and pituitary extracts. It is, however, a far cry from the ancient to the modern point of view regarding such substances. The ancients used these agents, calculating that their vile tastes and nasty odors would drive away the offending disease, while, by us, organ derivatives are employed from our knowing that chemical substances are elaborated and stored by the organs and when given off into the circulation promote the welfare of the body organism. This rational use of glandular derivatives is only 25 years old, but, in these comparatively few elapsing years, a vast amount of work has been performed by scientific workers everywhere, until to-day we are confronted by a bewildering literature filled with contradictions, over-exploitations, speculations and theories, but, fortunately, here and there we find a clear-cut, undoubted fact that stands as a monument of human achievement.

Unrestrained speculation from the very incipency of organo-therapy has attached stigma to this form of treatment. There has always been the over-optimistic type of worker who has held out greater virtues, as the properties of certain glands, than really existed as facts. Extravagant claims have actually retarded the fuller understanding of the possibilities and limitations of glandular therapy. So, let us recognize that we are surrounded both by existing limitations and by ignorance as to possibilities. Let us at once learn not to expect any panacea that will rejuvenate old men, or which will defer old age beyond a certain physiologic limit, nor can hopelessly anatomically defective minds be brought up to par. On the other hand, nearly every gland has its field of application. In many cases, the application is specific, and neglect to use glandular tissue approaches criminality. Persistence in the treatment on the part of the

physician is essential. Most of the glands, apart from such products as adrenalin and pituitrin, act so as to alter the metabolism. Such changes do not occur at once. For instance, no good results are to be expected from placing a mentally defective child on pineal medication for two weeks. Such treatment must be continued for months and even years.

One of the sources of error accountable for poor results may be ascribed to the chemical manipulation of glandular substances, with the desire to purify them and ultimately to obtain the active constituent in crystalline form. A chemically pure substance, active and freed from attending deleterious qualities due to contamination, is, of course, very desirable, but many glandular products are not standardizable and a mechanically nice-looking product may be attained at a sacrifice of activity. Except in a few instances, adherence to a product closely simulating the original tissue, is attended with better results, in the absence of any direct data regarding the nature of the substance stimulating the changes. This is especially true of such obtuse agents as the anterior lobe of the pituitary gland and the pineal body.

Very few of the hormones have been isolated in crystalline form, so that, for the most part, the properties of these hormones of the different glands are but meagerly understood. In general, they are the chemical means of correlation of the activities of the different parts of the body. They promote or moderate metabolism. In addition, special functions are attributed to some. Even with so vague a knowledge of the nature and properties of hormones, it is possible to indicate some lines on which with safety we may proceed in the application of these glandular derivatives. They are likely to prove useful in five different ways:

1. The most obvious and natural use is in the treatment of the diseases due to destructive lesions of the glands by which the hormones are secreted. In this substitution treatment glandular derivatives are used in a sound and rational manner. Typical of this use is the employment of *corpus luteum* or ovarian extract in the treatment of artificial menopause due to the removal of the ovaries.

2. Glandular derivatives are serviceable when there is bodily demand for more secretion than the gland supplies. For example, the simple parenchymatous goitre of young women is due to overgrowth of the gland in its effort to supply a greater amount of the thyroid secretion. When such patients are placed upon thyroid medication, these simple goitres in many cases disappear.

3. The derivatives of one gland may be substituted in a deficiency of activity in another gland. For example, where osteomalacia is present and attributable to ovarian malfunction adrenalin preparations are many times useful.

4. A large number of conditions exist where glandular products are beneficial but no connection is established between the pathologic condition and the gland function. Such may be called the "empiric use" of glandular derivatives.

5. The use of these glandular derivatives as drugs, for example pituitary extracts as an oxytocic, or adrenalin as a hemostatic.

In the foregoing pages I have tried to make clear the importance of the glands of internal secretion in health and normal function, the possibility of disaster that may come to the body through perversion of secretory function from disease or traumatism and, in the last paragraph above, it has been my desire to point

out the rationality of combating disease and aiding normal functions by the administration of preparations of these glands. Since the cells of the various organs may be influenced in their functioning by substances procured from other animals, the possibilities at once opened up are immense. Progress to the ultimate control of many complicated conditions, is limited only by the capabilities of the scientific workers to produce satisfactory preparations of established and uniform activity.

This is an all too brief outline of hormone therapy to-day. New pathways in this field of therapy are opening up yearly. The principles of hormone therapy explains in many respects the action of the older drugs and affords solid groundwork for future methods of treatment. For these reasons I commend the glands of internal secretion to your further interest and study.

---

### VOLATILE AND ODOROUS CONSTITUENTS OF HUMAN URINE.

At ordinary temperatures the amount of volatile acids in urine is very small, and the characteristic odor is not due to them, as has been stated. The lower fatty acids occur in such minute traces in normal urine, and are present in salts or in combination, so that they can only slightly, if at all, modify the odor. Sulphuretted hydrogen is given off by all urines, in the cold, when they are treated with dilute phosphoric or sulphuric acid. The volatile substances were obtained by acidifying a large volume of urine with sulphuric acid before distillation. Benzoic acid, derived from the hydrolysis of hippuric acid, was the principal volatile acid found, although in many cases the hydrogen sulphide present was sufficient to account for the total acidity. Fatty acids up to heptylic acid, and possibly hexahydrobenzoic acid, were also present in minute quantity. Phenol and para-cresol were present, also notable quantities of higher phenols. Methylamine and indole occur in traces in fresh urine; the amount of these bases increases on fermentation. None of these are responsible for the characteristic odor of urine. This is due to a neutral substance, urinod. It was obtained by acidifying 1,000 litres of urine with sulphuric acid, allowing it to stand for several days, distilling, shaking out the distillate with ether, and removing the acids, phenols, and bases from the ether extract by the usual methods. The residue was then distilled, the distillate again shaken out with ether, the ether extract being shaken with mercury to remove sulphur. The purified ether residue was then fractionated *in vacuo*. Urinod was thus obtained as a yellow oil, slightly heavier than water, in which it is insoluble, with a very persistent, penetrating odor of urine. A drop on a filter paper retained its odor for fifteen months. Its empirical formula is  $C_8H_6O$ : boiling point,  $108^{\circ}$  C. under 28 mm., or  $208^{\circ}$  C. under normal pressure; but it does not distil under ordinary pressure without decomposition. It is very volatile in aqueous vapor. Urinod is extremely poisonous; its relation to metabolism is not known. It may have some influence as a cause of uræmia. Oxidising agents at once destroy it; hence these are best for use for deodorizing urinals.—W. M. Dehn and F. A. Hartmann (*J. Amer. Chem. Soc.*, 1914, 36, 2,118, 2,136).

## Section on Commercial Interests

Papers Presented at the Sixty-Second Annual Convention

### THE SALE OF BIOLOGICALS.

WALDO M. BOWMAN.

"The present is the perpetually moving spot where history ends and prophecy begins. It is our only possession; the past we reach through lapsing memory, halting recollection, hearsay and belief; we pierce the future by wistful faith or anxious hope, but the present is based on fact."

So says a modern writer and we do not gainsay him truth, yet we build to-day with hope for to-morrow. The past is past—What of the future?—What of to-day?

It was 118 years ago that the practice of vaccination against Small-pox was introduced and some twenty years ago that Anti-Diphtheritic Serum was first marketed, but it is during the last decade that the greatest advances in Serum Therapy have been made, and our Biological Materia Medica has been so greatly enlarged by the various Serums, Bacterial Vaccines, Phylacogens and Sensitized Vaccines that are coming to play such an important part in the practice of medicines that when the physician of to-day is called upon to prescribe for his patient his mind turns in many instances to Biological Materia Medica for the remedy.

This being so, it behooves the pharmacist to be thoroughly informed, not only as to the different biological products, their distinguishing points, methods of production, usage in the treatment and prophylaxis of disease, but the methods of best preserving them in active condition and commercially of the most effective ways of bringing them to the attention of the physicians and the public.

That comparatively few pharmacists are keeping up to date on this rapidly changing line is an admitted fact, and failing to be posted they are naturally unable to take care of the demand that may be made on them for biological materials. The elaborate and expensive plants and complex methods necessary to the production of Serums and the modern Bacterial Vaccines makes it obligatory for the manufacturer to depend for distribution, and the physician and public for supplies on the dispensing pharmacist or other local source of supply, we should therefore be prepared to meet the demand for this class of material which affords a good margin of profit and for which the user naturally looks to the pharmacist.

Let us briefly mention the various Biologicals with their distinguishing points. Diphtheria Antitoxin is the only one at present official in the Pharmacopœia. Its method of production is fairly well understood. In the twenty years that it has been in use, the mortality from Diphtheria has been greatly reduced, danger of epidemic lessened and to-day its use is the first thought in this disease, and Diphtheria has ceased to be the universally dreaded scourge it was. Tetanus

Antitoxin and the Anti-Bacterial Serums, Anti-Streptococcic, Anti-Pneumococcic, Anti Meningitis, Anti-Dysenteric, Anti-Anthrax are all produced in a manner similar to Diphtheria Antitoxin by developing in horses by repeated injection of either a toxin or bacterial culture a high degree of immunity, the blood serum from these animals after purification representing the marketed product. Normal Serum, the purified serum from the blood of healthy horses is used in the treatment of Hemophilia and has quite an extensive sale.

Small-pox Vaccine marketed in capillary tubes and glass or ivory points is the original Biological; its method of production is doubtless familiar to all of us, and commercially this product is of considerable interest.

Bacterial Vaccines are the product of Bacterial cultures on a suitable media, they representing commercially either the solution of the product of a specific organism, or of several combined varieties, their medicinal value lying in their property of raising the resistance power in the body to infection; that is to stimulate the Phagocytes that nature provides for fighting infection. The principal commercial varieties are Acne, Coli, Diphtheria (for immunity), Neisser (Gonococcic) Pneumo, Staphylococcic, Streptococcic, Typho and various combinations of these forms.

Phylacogens are "Sterile aqueous solutions of substances generated by bacteria grown in artificial media," they are, substantially, mixed bacterial vaccines, those bearing a specific name showing a preponderance of the named organism, the principal varieties are Mixed Infection, Gonorrhoea, Rheumatism, Pneumonia. Their use medicinally is similar to that of Bacterial Vaccines, they following Shaeffer's theory that in all infection, the growth of all forms of pathogenic organism is stimulated and to successfully combat disease all forms of infection must be combated.

Sensitized Bacterins, marketed as Serobacterins, are prepared after the method of Besredka, by bringing live bacterial cultures on artificial media, into contact with the blood serum of an animal which has been previously rendered immune to the specific infection; that is, one whose blood has been heavily charged with antibodies, a precipitate is formed which is freed from adhering serum, purified and killed mechanically, an aqueous mixture with suitable preservative representing the commercial product. They are used medicinally in the same way as Bacterial Vaccines and Phylacogens; the claim being made that they produce quicker and more lasting immunity with less reaction, the marketed forms are practically same as the Bacterial Vaccines. Tuberculins, for diagnostic and therapeutic use, are produced from cultures of the Tubercular Bacillus. They are marketed in various forms both concentrated and dilute and are largely used by a limited number of physicians.

Various cultures of the Bacillus Bulgaricus both in liquid and dry form are becoming important commercial products; following the theory of Metchinkoff of Paris they are used in the treatment of various conditions due to intestinal infection, cultures are also marketed for the production of buttermilk, the use of which is along the same lines.

That it is manifestly impossible for the pharmacist to carry in stock all of these items is evident, but the well-regulated stock should include in addition to Diphtheria Antitoxin and Small-pox Vaccine, Normal Serum, Anti-Streptococcic

Serum, Tetanus Antitoxin, Anti-Meningitis and Anti-Pneumococcic Serums and an assortment of Phylacogens or Bacterial Vaccines, including Acne, Gonococcic, Streptococcic, Staphylococcic Typhoid, both treatment and immunizing, and Mixed Staphylo Bacterin, the quantity to be carried must necessarily vary in different localities and should be regulated by the volume of business (that is, the number of people you might normally be called on to serve), and the distance from a dependable source of supply. It should be sufficient to care for a reasonable demand and where the source of supply is so situated that fresh stock can be obtained within twenty-four hours a representative stock might include in Diphtheria Antitoxin six packages of One Thousand Units, and two each of 3000, 5000 and 10,000. Twenty vaccinations against Small-pox and double this amount of all except the 1000 Unit Diphtheria Antitoxin should the source of supply be more distant.

Of Anti-Streptococcic Serum and Tetanus Antitoxin, six curative packages each should be carried. For in treating severe cases one package is used every six hours; two immunizing packages of these should be carried as well. A smaller amount of other Serums will suffice as will of the Bacterial Vaccines in which it is advisable to carry in stock the larger packages. After you learn your trade and have established a demand for these preparations, a little care and observance will enable you to keep the stock in good condition, but do not overstock vaccines, as in many instances the sale of a single package is all you may expect for a case under treatment. The manufacturers, in most instances, provide for exchange of unsalable stock, but with this material it is very easy to tie up an unnecessary amount of capital.

As to the best methods of preserving, the manufacturers of the various Serums and Vaccines have given a great deal of time to experiments along this line, the results of which show in what manner they may be best preserved,—that is, their activity retained for the longest period.—They should be kept in the dark, this is easily done as they are marketed in light-proof packages. These packages, also, in most cases, bear a date after which time they should be no longer sold. They should be kept at an even temperature preferably at 40° F. or thereabout, it having been shown conclusively that the rate of deterioration of Serums stored at this temperature for a considerable time is 16% as compared with from 30 to 40% at the ordinary room temperature, while the deterioration of Small-pox Vaccine is much more rapid, in warm weather, it often losing its efficiency in a few days, while if kept at a low temperature its activity is retained and at 10° F. it may be kept for a long period.

The rate of deterioration of Bacterial Vaccines and Phylacogens is still somewhat questionable and there is no doubt but that they retain their activity longer if kept cold. Temperature being such an important factor, it is advisable that all biologicals be stored in a refrigerator so constructed that the packages may be kept cold, dry and slightly and at the same time be readily accessible. One constructed entirely of metal or porcelain, is preferable and if properly arranged will keep your stock in good condition and may be made a valuable advertising asset; and also of use in storing other preparations liable to rapid deterioration such as Ergot and Digitalis preparations, Culture Media, etc. Personally, I have found a refrigerator of this kind a most valuable addition to store equipment.

Now, having a stock of Biologicals and providing for their being well stored, the question of sale is of paramount importance; during the first few years that Diphtheria Antitoxin was on the market, the use of it was confined principally to the specialists in diseases of the throat. Among the medical profession to-day its use is well nigh universal; all schools and classes of physicians resorting to its use when the opportunity presents itself. The newer Biologicals have been used until lately by comparatively few physicians, but the opportunity for business to-day, and in the future, lies through those physicians in general practice whose investigation along Biological lines is comparatively limited. These men are possible good friends of your pharmacy, their patients are your good customers and will turn to you for supplies. Be prepared when the opportunity comes to talk Biologicals to these men, study the literature on the subject that may be easily obtained from the manufacturers; read carefully the various articles that appear in the trade journals from time to time along this line and if the opportunity presents itself visit one of the larger Biological Laboratories where you can get the information at first hand, *get this information* so that when the opportunity comes to make use of it, you will not have to say "Well, I don't know much about that, but maybe I can find out," but will be able to identify the particular Biological that is needed for the case in question. Remember that the psychological factor in making a sale is an important one and that you must know the value of your merchandise before you can impress its value on another. I hear someone say, "We are not practicing medicine for the physicians, let them do that for themselves; we're in business to supply what is called for, not to tell what is wanted." Quite true, but neither are you practicing pharmacy for yourself unless you are thoroughly familiar with the composition and therapeutic value of the medicines and agents that are used to-day, and if your interests are Pharmaceutical rather than purely commercial, you will be up to the times. If not, you will be distanced by some more energetic fellow who has kept up-to-date and is willing to impart his knowledge when the opportunity is at hand.

Advertise Biologicals to the Medical Profession, informing them that you are carrying a complete assortment, stored under proper conditions, and that you know their therapeutic use. Advertise them too, to the public, for with the very considerable amount of publicity that has been given to Bacterial and Serum treatment of various kinds for the last two years in magazines and the daily press, the better read people have a more or less defined knowledge of Biologics in the treatment of disease and will be attracted by your advertising a line of medicines that they know are coming into more extensive use continually.

Personally, I have used street car advertising with marked success, running for some time a card calling attention to my installation of a special refrigerator where biological products were stored under ideal conditions; asking inspection of it, and saying that these products were supplied only on physician's orders. Also a card on Anti-Typhoid inoculation for the production of immunity against Typhoid Fever at a time when this disease was prevalent. Use methods of this kind or well-worded newspaper advertising, coupled with window displays of dummy packages and display of attractive placards. Your good friend the "general public" is very amenable to suggestion, if it be timely and about something that is of interest; so advertise Vaccine when Small-pox is an epidemic. Typhoid

Vaccine when this disease is prevalent, Diphtheria Antitoxin at appropriate seasons and Tetanus Antitoxin before the Fourth of July.

The margin of profit is good and people will respond, your physician will benefit as much as you and if your advertising is dignified you can not be accused of overstepping the bounds of proper publicity.

When the demand comes to your establishment, see that you are there to take care of it or have some one who is equally well informed, don't let the junior do it all; but be awake when opportunity comes your way, for we are told that "she knocks but once at every door."

As to Autogenous Vaccines, that is, Bacterial Vaccines prepared from cultures of individual cases for the treatment of such cases, on account of the apparatus and time necessary for their production, these cannot be undertaken by the pharmacist with any degree of success, except in rare instances, but an arrangement with the larger manufacturers is available which will enable you to take care of any demand that you may have. Rabies treatments may also be taken care of in this way, and while these items do not afford a large percentage of profit, they are handled on a cash basis and you have no investment to make.

So far, we have considered only the Biologicals used in human practice. In the veterinary line there is a fertile field for those stores which are so situated that they are able to get in touch with the veterinary and farmer trade and to obtain business along veterinary lines, for a profitable trade can be readily established. They use Biologicals largely and the present indication seems to be that the horse is far from being displaced by the motor, while the demand for dairy biologicals continues to increase.

Tetanus Antitoxin in veterinary practice is highly successful and the use of immunizing doses of Tetanus Antitoxin is a routine procedure with the better veterinarians in all surgical cases. Anti-Streptococcic Serum has a very considerable demand, as has Veterinary Diphtheria Antitoxin. Among the Bacterial Vaccines, Mixed Bacterins of Polyvalent type, Pneumococcic, Streptococcic Bacterins and Anthrax and Abortive Vaccines and the various Veterinary Phylacogens are considerably used, while the demand for Tuberculin and Mallein is steady.

In point of quantity, Hog Cholera Serum is the largest item among Biological preparations, the amount used in some sections being enormous.

These items can be advertised to farmers and veterinarians and a very profitable business be secured with little effort where proper conditions exist.

Summing up the whole matter—If you are not developing the business in your territory along Biological lines you are neglecting a great opportunity for profitable trade.

Their use has shortened the duration of many diseases and practically eliminated others. It has decreased the need for ordinary medication to a marked degree and so curtailed your profits to some extent. What the development along these lines will be in the next decade we hesitate to predict, certainly there will be great advances and great developments. Be well informed and get the business in your field while it is developing, and keep in mind that saying "He who knows and knows that he knows is a wise man."

## DISCUSSION.

Chairman Mason said that it had been his contention for a number of years that the future of the druggist was right along this line of biological products; that the materia medica is going to diminish in importance, and the future is in the direction of biological products. Chairman Mason said further that he was afraid that the American druggists have not appreciated this fact, and for that reason he had solicited these two papers on the subject, hoping that the authors would act somewhat as missionaries. The Chairman said if there were any others present who could give their experience in the sale of biological products, he would be delighted to have them do so.

Mr. Cornelius Osseward, of Seattle, said it had been his experience that biologics were getting less attention from the druggists than any other line that has recently been put in the drug-stores. He spoke of that because of the number of clerks he had recently employed, it had been his experience that everyone of them came to his store knowing nothing whatsoever about biological products, and the result was that he himself had to be "on the job" all the time, unless he got a man who would take enough interest in the subject to take it up and study it. It did not take much time for a man to become posted on the subject. It was a good line, and there was a good profit in it, and the druggist could get as much as forty per cent. plus his cash discount on the goods, and he did not see why the druggists do not take up that line more than they do. In his case he was somewhat at a disadvantage in that he was so far away from the eastern markets that he had to carry an immense stock, which made it necessary for him to have between twenty-five hundred and three thousand dollars invested in biologics. The reason for this was because the physicians insisted on goods made by different manufacturers, and this required carrying, sometimes as many as five different makes. This is a hardship, and it meant the investment of a lot of money that really was not necessary, with druggists who were close to the market. Where there was but one man in the city who handled biologics, he did not need to have more than one line because he was independent. In his case, there were five or six other druggists who handled biologics to some extent, which made it necessary for him to carry most of the makes which were on the market, which was the only disadvantage he claimed for carrying biologics in his vicinity.

Mr. Selzer said he used to handle serums, but, because the city now distributed it free, to rich or poor alike, as well as vaccine virus, he had discontinued doing so.

Mr. Holzhauer said, the Board of Health in his city, supplies biological products to rich and poor alike, and the Board has stations for their distribution in various drug-stores throughout the city. This was true of all the biological products with the exception of a few which are not in common use. The Board of Health had charge of the whole thing and the druggists simply acted as distributing agents.

Chairman Mason asked Mr. Holzhauer what the druggist got out of it, to which question Mr. Holzhauer replied that they got nothing, except glory. (Laughter.)

Chairman Mason then asked Dr. Charles T. P. Fennel, of Cincinnati, to explain why it is that any city Board of Health distributes free antitoxin to any one except the indigent.

Dr. Fennel replied that he was just going to say that the same conditions existed in Cincinnati with their Board of Health, and they had the additional misfortune of having a surgical instrument house in their city which catered to the medical profession, and offered them a twenty per cent. discount on their goods, with the result that the druggists who carried a line of surgical instruments, were placed at a disadvantage, and only had calls for these articles in the night time when the Board of Health and the surgical instrument house were closed, and consequently there was no profit in these lines in Cincinnati.

Mr. Holzhauer said, originally, in his city, the Board of Health provided antitoxin only for the poor, and the way the change was brought about to provide it to the people who were not poor, was by a gentleman coming into his store one night who had a child sick with diphtheria. In this case the culture had been sent to the Board of Health Station, and the report made that it was a case of true diphtheria. The gentleman on getting this report, wanted a bottle of antitoxin, but was told he could not have it as he was not poor. Mr. Holzhauer said he saw the ridiculousness of the position and he went to the Board of Health about it. As a result of this incident the Board of Health started their own department and developed along the line he had indicated.

Mr. E. H. Thiesing, of Cincinnati, said he would like to call attention to a few interesting situations which had existed in Cincinnati some years ago in regard to this very product; that the druggists woke up to the fact that they were selling no antitoxin at all; that the local association then took the matter up and after some investigation it was discovered that two firms in the city were delivering antitoxin to the physicians at the same prices that the druggists were paying for it, with a two per cent. discount; that the druggists finally decided to make an effort to have antitoxin of their own brand, and they got in touch with the Board of Health, and with their coöperation, the local association has made an arrangement with the Memorial Institute of Chicago, he believed, by which the druggists are now selling antitoxin in quantities of five thousand units for \$2.25 to the public, against the former retail price of \$7.50; that the association had in this way brought back to the druggists about eighty-five per cent. of the trade in antitoxin, whereas previous to the druggists making this arrangement, the sale was in the hands of two firms in the city.

Mr. Thiesing said he mentioned this because it might be advantageous to do this in other places. The antitoxin is now handled in his city through the local association, and is also being supplied to some small towns outside of the city, and they can sell it at this same price. He thought 3,000 units were sold at \$1.50, and 1,000 at eighty cents. The arrangement had been quite an advantage to the public, and had brought back to the druggists the sale of the antitoxin, which they had not had for a little while. The arrangement had been brought about only through cooperation with the Board of Health, and each package of the goods was marked with the approval and consent of the Cincinnati Board of Health.

Mr. Holzhauser said they had at his store arrangements to receive diphtheria slides which went to the Board of Health, and in twenty-four hours the physician knew whether he had a case of diphtheria or not. Otherwise, the physician went on treating his case two or three or four days before he absolutely made up his mind whether he had a case of diphtheria. This was true with other diseases all the way down to tuberculosis. In a suspected case of tuberculosis, the sputum cup is used, and the sputum is examined, and in twenty-four hours the physician knew whether he had a case of tuberculosis.

He never liked to turn his back on anything that provided profit for the druggist, but it did seem to him that it was a case of doing the greatest good to the greatest number, and with the Board of Health managing this thing he thought it was a great deal better for the patients who were suffering from these diseases to have it under such control, rather than to have a physician "fool" along for a week before he made up his mind whether he had a case of typhoid fever, for example. As it was now, the physician knew inside of twenty-four hours, and it seemed to him, while he received less profit, still it was a great benefit to the community at large.

Mr. Selzer said in his city all the police stations furnished antitoxin, and the physician did not have to go down street to get it; that the police stations supplied it, and the physician did not have to tell what it was for.

Chairman Mason called on Mr. Leonard Seltzer, of Detroit, for some comments on this subject. Mr. Seltzer said he had not been able to determine how far the sale of biological products had been interfered with by the distribution of such products by the Boards of Health. The sale of such products has been somewhat interfered with, but he had not seen much interference, so far as antitoxin was concerned. He did not know, of course, how much he did not sell, but simply how much he sold. So far as the sale of biological products was concerned, it seemed to be only a good means of pulling other business. It was a good plan, in order to keep in touch with the physicians, to have a full line of biological products, and keep them in good condition.

Mr. Holzhauser asked Mr. Selzer how much he lost by deterioration? Mr. Selzer replied, he had never figured it out, but he did not remember of having lost a single package of antitoxin, although once in a while he had lost some of the others.

Mr. Bowman thought they were losing sight of one very important thing in this discussion; that the thing to do was to make the public believe that your own store keeps biological products in better shape than any one else in town. A certain number of people in every community knew who had the best goods, and they will come to you because they know your goods are all right, and you know what you are doing, and they do not know what kind of goods this Board of Health "stuff" is, particularly with the newer biologics. The druggist should put himself in such shape before the public that when they need any of these things, he will be the first man to come into their mind, and they will go to his store and buy them. It was good advertising to the public and that was the one great point in the sale of biological products.

Mr. Osseward agreed heartily with the last speaker, and said that the pharmacist should so conduct his store that the public would come to him. He further said that he had an incubator in his store, which the physicians use. They put their cultures in this incubator when they want to find out the nature of an infection, and, in the case of diphtheria, after the physician has left his culture, he comes back to the store and gets his culture before he goes to the patient. The physician makes his test, and the culture incubates in the store, and the next morning the authorities come around to the store and inspect the culture, and the physician gets the report and comes to his store, because there is where the culture was incubated. The incubator was one of the best investments he had ever made, it had cost him a hundred dollars, although you can get a small one for fifty dollars. It was because he had this incubator, that when the physician got his antitoxin, or his biologics, he came to him, as their store had the reputation of having everything that is on the market in the way of biological products.

Chairman Mason said he thought they had perhaps given sufficient time to this subject, and he simply wanted to say in concluding the discussion that both Mr. Bowman and Mr. Osseward of Seattle have made a brilliant success in the sale of biologic products, and that they have shown what can be done by giving some study and attention to the subject.

## BUILDING UP TRADE IN SPRAYING MATERIALS.

---

H. F. RUHL, MANHEIM, PA.

---

The use of insecticides and fungicides is greatly increasing, not only in fruit growing but also in general farm practice. Wheat and other grains need to be treated (before seeding) with Formaldehyde solution to prevent smut. Wheat is treated in the granary or grain elevator with Carbon Disulphide to prevent a sort of a "miller" which destroys much wheat. Potatoes are soaked, before planting, in Formaldehyde or Mercuric Chloride solution to prevent scab. Potato vines are sprayed with Bordeaux Mixture to prevent blight, and with an Arsenate like Paris Green or Lead Arsenate to kill potato "bugs." The list might be lengthened, but even this short list shows the advantage of being prepared to supply a need that is bound to grow.

The essential requisite for building up a trade in this line is familiarity with the subject; knowledge of the necessary materials; strength of solutions; the right time of application. This knowledge may be acquired by reading Federal and State bulletins. In Pennsylvania, Volume 1, No. 1, of *The Bi-Monthly Zoological Bulletin* issued January, 1911, under the direction of Prof. H. A. Surface, covers the subject thoroughly. No doubt similar publications are issued in other states by the Experiment Station or Department of Agriculture. If possible, get into touch with County Farm Bureau Agents and successful fruit growers. If state officials give demonstrations in orchards, attend these.

One other essential is advertising. A pharmacist may be thoroughly familiar with the subject and have the necessary spraying materials and yet fail to do much business. By impressing upon possible customers the fact that he knows and has the goods, through the medium of advertising, will greatly increase his chances for success. The writer has used window displays in the fall by showing perfect specimens of apples with a placard "Plan to have fruit like this next year by spraying." No spray materials were shown. As the time for spring spraying approached spray materials were displayed. Newspaper space has also been used, giving directions for preparing solutions. After the edition of the paper was run off, the form was lifted out and placed in a smaller press and a quantity of counter slips run off. The wording of one of these slips was as follows:

## FOR POTATO BLIGHT

Use Bordeaux mixture. Make stock solutions as follows:

Tie 25 pounds copper sulphate in a cloth bag and suspend just below the surface of 25 gallons of water.

In another vessel slake 25 pounds of lime and add enough water to make 25 gallons.

When ready to spray to make 50 gallons of mixture; take 5 gallons copper sulphate solution and enough water to make 45 gallons. Stir up lime mixture and strain 5 gallons of it into the 45 gallons above and it is ready for use. If bugs are present add two or three pounds of arsenate of lead and apply both at one spraying.

RUHL'S DRUG STORE,

Telephone 608 L.

51 S. Prussian Street, Manheim.

Such printed directions save the pharmacist time as no verbal directions need be given.

Most of the chemicals or drugs needed to supply this trade are carried in stock in nearly every pharmacy, hence there is no additional outlay. Only the fact that some of these, like sulphur and copper sulphate, are needed in large quantities makes it necessary to buy in larger quantities to get every possible price concession so as to be able to sell reasonably.

## DISCUSSION ON THE ANNUAL INVENTORY.

Chairman Mason proposed as a topic for discussion the taking of an Annual Inventory.

MR. NITARDY:—"Our firm is a large one with a quarter of a million dollars of invested capital, divided into six stores, a supply department and a manufacturing-department. The inventory of all of these is taken in one day, each department looking after its own. The office supplies inventory-books, the pages of which are printed similar to an invoice. The pages of this book are torn out as filled and then they are bound in a large volume together. Thus we always have a definite sheet or series of sheets for each particular class of articles. Our inventory usually contains between fifty and sixty thousand separate items, that is for the main store, and this work is finished in a week's time."

MR. SCOTT, of Detroit:—"We take an annual inventory and we try not to exceed seven days in taking the inventory of our seven stores. We simplify the taking somewhat by listing the goods we make at a certain figure which figure they had found did not vary much from \$10,000. This simplified the work and eliminated many objectionable features of it. The final figuring of the inventory is done by the office-force. The man who does not take an inventory does not know what he has in stock that is unsalable and which oftentimes can be exchanged for salable goods. An adding-machine we have found to be a very useful article in making an inventory. Much time can also be saved by massing certain things, such as, for instance, herbs. Taking an average price for such herbs, we find that we have one or two hundred pounds of herbs at a price of twenty-four cents a pound. This method saves detail. The same method can be adopted in the case of tinctures, elixirs and like goods."

The question being raised as to how depreciation of fixtures should be taken care of, Chairman Mason called on Mr. Barker to answer that question.

MR. BARKER:—"Soda fountains, carbonators and things of that nature depreciate about ten per cent. a year. Shelving and show cases about five per cent. Cash registers should be charged off at about ten per cent. It is well to allow a liberal depreciation on store fixtures, so that when changes have to be made they have already been allowed for."

In reply to a question Mr. Siebert stated:—

"I think it necessary, in the adjustment of fire-losses that the druggist should be able to state the actual cost of the articles for which he desires to receive compensation. To present an estimate of 'fluid extracts, so much' would not be acceptable to the present-day companies. That used to be the case, but companies have become much more particular regarding this. Many druggists do not take an inventory more than once in ten years and such men would find their case a difficult one if they had a fire in their establishments. The first thing asked for now by the companies is the inventory and if that is not forthcoming adjustments will be difficult. Annual inventories are absolutely necessary for prompt and satisfactory adjustment of losses."

MR. SHRINER:—"I have had a little experience with fire. The fire was caused by a person who had a position in my house, and as a result of it a garage burned down. The garage cost \$5,000.00 and it was insured for \$600.00 only. The fire insurance adjuster, who represented several companies, was a friend of mine, but when it came to adjusting the loss I found out that, friend or no friend, the adjuster wanted to know precisely about every item of loss. The insurance people looked the thing over and I was very much surprised at the system which they used in trying to make an adjustment to the satisfaction of their companies and the stockholders of the companies. The fire resulted in a total loss to me practically and I got my \$600.00, but the insurance companies were not satisfied to simply measure every foot of ground; they wanted to know how large the building was; they looked at the charred remains and everything else, and I noticed that it was all written down in detail, and I admired the system. It opened my eyes."

"I have been in the drug business for about thirty years, and during those thirty years I have taken an inventory twice (laughter). I started to take an inventory nine years ago, and it took me six months to finish it (laughter), and when I finished, I had to commence over again because I had bought a whole lot of things in that time, and we had used a whole lot

out of the different containers. I tell you it was a proposition—it was a job! Everything was accurately measured. My son and I, we worked like beavers to get everything summed up. I said to my son, 'Al, get everything and mark it down so many quarts, so many gallons, and so forth. Let's start in and get graduates and measure it off.' So we measured it off, and after we had proceeded a while, I said, 'By golly, we are up against it, ain't we?' (Laughter.) And Al said, 'Well, you have got to know what you are worth here, you are always saying you never know what you have in this store.' Says I, 'Certainly we should.' 'You are getting all you want, ain't you?' 'Well,' says I, 'I wish we were through.' 'And just now you said I could go on alone and finish this job! I haven't had a Sunday for two months since this has been going on!' Well, my friends, that is all right. When it was all over, I was considerably pleased, for I found that I was worth a few thousand dollars more than I thought I was, and I said to Al, 'See what your father has done!' (Laughter.)

"I run my store upon the 'European plan.' Everything is alphabetically arranged, and there is not a thing in the house that I cannot lay my hand on, even in the dark, although another fellow might not find it so well, because they do not understand the system. There is not a shelf that is not arranged alphabetically. But I have noticed, sometimes, when I got a shelf mixed up a little, I had an awful time finding things again (laughter). You know, I would be using two or three bottles in making a prescription, and place them back on the wrong shelf (laughter.) Still, we haven't had much trouble in that way.

"But as I said, I hardly ever took an inventory, and this insurance gentleman said, 'Now, Mr. Shriner, how about that inventory?' I says, 'I took an inventory about five or six years ago.' He says, 'Do you think that would stand in court?' I says, 'I don't know, I can't tell you whether it will stand in court.' He says, 'It will never stand in court, if it was made six years ago.' You must take an inventory every year and you must itemize these things, because when you are called upon, you are supposed to show what you had in stock, and you must be pretty sure you had the things in stock so that the amount of the loss can be determined.' 'Now,' says I, 'I am going to take an inventory right away,'—but I haven't done it yet. (Laughter.)

"As I said, I have been a druggist for thirty years, and I have never believed in mixing other lines with my drugs in these thirty years. I have kept exclusively drugs. They are the important things, and no side lines,—no candy, or anything. But my son has just graduated from college, and that is where the trouble begins. He came home one day, and there was a family gathering. I says, 'What does this mean, everybody being here; what is the matter?' You see, I commenced to 'smell a mouse' somewhere (laughter.) My wife says, 'Al has something to tell you; he has something he wants to talk over with you.' I says, 'He wants to stay with me doesn't he?' 'Sure, he wants to stay with you.' Says I, 'He wouldn't leave me now after I had educated him, and I have been sending him to school for so many years? I think I would like to get some help out of him.' And she says to me, 'Surely, but under a certain condition.' 'How?' And she said it again, more emphatic than before. 'Well,' says I, 'what is it?' And Al says, 'Well, you know the way you have been running this store.' 'Now,' he says, 'this won't do any more. It won't do to be in the back room all the time, and when somebody comes in the store, crawl out of that back room.' (Laughter.) Says he, 'This has got to be changed.' 'Changed?' says I. 'Don't argue with me,' says he, 'I am doing the talking.' Says I, 'What are you going to tell me?' 'Well, I will tell you, we are going to get a soda fountain.' 'A soda fountain,' says I, 'what do I want a soda fountain for? I suppose I will be going in the confectionery business next.' 'No use arguing about it.' 'Well, what else do you want?' Says he, 'And we are going to put in a line of candy.' Says I, 'Are you going to make a Huyler's store out of this place, what else do you want?' 'Get a high grade line of candy,' says he. 'What else do you want?' 'We want some kodaks,' (laughter). 'I never looked through one in my life,' says I, 'how could I sell a kodak?' 'I will do that,' says he, 'we will get them in stock.' 'Anything else you want?' 'Yes, we want a good line of paint.' 'Well,' says I, 'that is pretty near the limit, do you want to start a wholesale house?' 'Don't mind,' says he. And then mother spoke up, she says, 'Yes, you will have to do something. There is no use talking,' she says, 'you want to keep Al with you, and he is going to make this his life work.' Says I, 'Now let's talk this thing over. Where did you get all those foolish ideas?' 'Why, foolish ideas—' and he commenced to bristle up, and I was surprised. I never saw him with fight in him before. Says I, 'Is that what you learned in college?' (Laughter.) 'Now, look here,' says I, 'I want to conclude myself. We never want that kind of stuff, and we want to put in our time with pharmacy and *materia medica*, and everything else, and I never heard such kind of business from my professors when I went to school. I can't understand how you learned all this, and bring it up here in my own house, and expect me to go in and trade in different things I don't know anything about,' (laughter.) Says he, 'The times have changed.' 'Yes, I am very well aware of that, that the times have changed,' says I.

"Well, to make a long story short, what do you suppose I did? I ordered the soda fountain; I ordered some cameras,—a monkey business (laughter).—and I made a contract with a paint house, and got a high grade line of paints, and then I looked around for a high class of candy. Well, it is all right! (Laughter.) Then I did not stop at that. I took up all the fixtures that were in there and put them in the back room; all of those things with their glass covers,

and put them in the back room, and ordered new fixtures for the store. And here is the thing I want to talk about,—the old prescription case, that dear old friend of mine, always behind it, you know (laughter), and I had commenced to love it too, and that is a fact, but my son, with his new fangled ideas said it had to go, and he had made up his mind that he was going to have a prescription room. Oh, the times are changing! By golly (laughter)! there is no use talking about it! My son said, 'I am going to make a prescription room in the rear, and it is going to have hot and cold water.' You know, I had never had hot water before in all my life in the store, always had cold water, but we have hot water now (laughter), and in this prescription room we are going to have nice shelves, all under cover, with all the chemicals, and everything else that is necessary for prescription use and we are going to have show-cases from the top to the bottom,—going to do it up brown while I am at it (laughter). And behind this old prescription room there used to be a wooden partition,—my gracious! I will never forget the trouble that gave me when I had it torn down from the plaster and dirt, and everything else, and we are going to have an ice cream parlor there now (laughter). I have ordered five or six nice tables, with glass tops, so that everything is sanitary, and about thirty or forty chairs. I said, 'I am going to do this thing up right.' (Laughter.) I says, 'I have been operating under the old system for thirty years, but we will have the new system now.' Everything will be thrown out of the store, and we will put on new wall paper, and get new fixtures, and everything else, and get these dimmed lights that throw the light softly down from the ceiling. I am going to put them in (laughter).

"And talk about your sanitary business! I have given an order for a show window that will be closed entirely, and be made out of nice quarter sawed oak from top to bottom, so that no dust can get in there, and in the winter time, in case it gets cold, the window will always be clear, and now I am getting steam put in the building. The landlord kicked and kicked,—oh, didn't he kick. He said it would cost him \$45,000.00 because he would have to put it in the whole block, as the other tenants would want it, and they won't want to pay any more rent, but after a while the tenants all agreed they ought to have steam and were willing to pay for it. So that little town is going to boom now, I tell you, and so far as that goes, I don't know whether I am going to make a success of it or not, but if I don't make a success, I am not going to worry. The goods are there, and we are going to sell them, and that is what my wife said. My wife, you know, is my partner in everything, only I haven't got anything to say. That is all. (Laughter.) But we want to give the boy a chance. She said, and I don't know, 'They say we ought to have these side lines in, and all like that.' And if we have got to have them, well, we will. It is a question to my mind whether they belong to the drug business or not. I have always considered the drug business as a profession, and not a commercial business, and I have spent many hours trying to do well to the public in general, and I may have done some good in my small way, but I can't do at all as I used to. Years ago,—twenty-five or thirty years ago, people would come to us, and ask our advice, and we would give them something that would help them, with very few exceptions. This thing is changed, and the doctors now prescribe for this thing and that, and people rarely go to the drug-store now. It seems to me as if the physicians controlled the public in general now and we are forced, without any doubt, to go into different lines. These are things we have got to think about, and think about very seriously, and certainly the best thing to do is to stock up on things that will sell, and will not lose their value, and will not spoil on our hands. This is a thing that ought to be given deep serious consideration. We drug men in general do not get together enough, and there seems to be a difference between them when a druggist meets a druggist. There is not the comradeship that there should be, and we do not greet each other with out-stretched hands as we ought to do. We are not kind enough to one another. There is something strange about it.

"I am sure that all the organizations should come together, even if we do not know each other. As long as we are druggists, and have confidence in each other as men, and as students of human nature, and so forth, we ought to talk to one another, and be kind to one another, and if we do that, we are going to succeed as well as is any other business in the country, and we are going to have coöperation, and we are going to have an organization that we can all get behind. We druggists should not be afraid to tell one another about our business, and what we are doing to a certain extent. We should be friends. Of course, there are all kinds of druggists, as well as customers, and we should be like contractors going after a job; if they don't get it, they try to get another one.

"My one hope and wish is that the druggists can be more democratic with each other, and that they will not slight each other as much as some have been. There is no reason why we as druggists should not succeed, and I hope that we will find some way of making a memorandum of our stock without the necessity of spending six months to do it. (Laughter and applause.)"

MR. SCHAFER: "The question of inventorying drug-stores in detail is clearly an impossible one, without getting up something which is untrue and incorrect and which will not stand in the courts. The proper way to avoid this difficulty is to eliminate the clause in the insurance policy requiring the taking of an annual inventory and to insert in its place a distinct statement that such inventory is waived. Only one company had declined to accept a policy of

this kind and they formerly accepted such policies, discontinuing that practice about two years ago.

In order to meet the situation and in view of the fact that the National Board of Underwriters were experts in their line of business and knew the difficulties of making a drug-store inventory, I offer the following resolution:—

"That a Committee be appointed to take this matter under consideration and to have authority to present it tentatively to the National Board of Underwriters, for the purpose of getting some satisfactory clause in the insurance policies which would apply to the drug fraternity."

CHAIRMAN MASON:—"It should be understood by the Section that the motion if adopted would but express the views of the Section. The matter would then be obliged to go before the General Session for their action."

The motion was adopted.

---

## DISPLAYING CONFECTIONERY AND COUGH DROPS IN BULK.

---

FRANKLIN M. APPLE, PHAR. D.

---

This is an age of intensive advertising, which includes displaying one's wares to the greatest possible extent, so as to catch the eyes of the shoppers and create in them a desire to purchase the goods exposed to view.

Whether it is proper or improper to thus display one's merchandise depends upon the nature of the goods, and the care taken to protect them from destructive or contaminating influences.

I am led to pen these lines by practices that have come under my notice, and by comments that have been heard concerning customs that are followed by some of those of our calling, as the intelligent, observing members of society of to-day are becoming more and more critical in their standards of cleanliness and hygiene.

It may be proper to display, unprotected from dust and dirt, such goods as are not intended for consumption by mankind, those which can readily be cleansed by using a brush or duster, such as building materials and supplies for stables, but to offer for sale in an unhygienic and uncleanly condition commodities intended for internal consumption by mankind, is a very reprehensible practice that will not fail to unfavorably react upon those merchants who so flagrantly disregard the health and interests of the public.

This is especially true of those of our calling, who are looked up to by the public as being possessed of greater knowledge concerning hygiene and bacteriology, and who are presumed to be a higher class of merchants than those who have no educational standards to respect or maintain.

From the March, 1914, issue of Huyler's Hints I will quote as follows:—

"People are very exacting as to what comes from a drug store; not only must the goods be of the best quality, but the packages in which they are put up must appeal to the sense of neatness. The dry-goods clerk, the shoe clerk, the grocer—in fact, salesmen in all other trades—do not care much about the appearance of the packages they send out. A sheet of paper twisted or rolled around the article, a piece of string, and the thing is done; and nothing better is expected. But with the druggist it is different. We wonder how many druggists appreciate the effect of a neatly-tied package or a simple, neatly-printed label, upon their customers. And yet we know of people who prefer a certain store to another for no other reason than that the goods sent out of it are neater than those coming from the other."

What has been most truly stated by this editor concerning the containers and

the labels for confectionery is unquestionably true concerning the confectionery itself, including in this class of merchandise medicated confectionery, known under the trade name of cough drops.

There has arisen a custom to offer for sale cough drops contained in a wooden box, which has no provision for protecting the goods from dust, dirt and filth, which method of displaying such goods should be made a misdemeanor, punishable by a fine for both the manufacturer of the goods thus displayed and the vendor thereof.

One manufacturer and distributor of cough drops, displayed in such a container, furnished by them, also offers for sale sponges packed in containers which are thus described:—"Packed in an attractive box with transparent top, suitable for counter display; keeps the goods on view and free from dust, etc."

This appears to me to be inconsistency of the highest type—protecting "from dust and etc.," a commodity that can readily be cleansed (and which usually is well-wetted before it is offered for sale, in order to add to its selling value), and sending out another commodity, intended for internal use, that cannot be cleansed before ingestion—and some of such goods that I observed on sale in drug-stores were so dirty and filthy that they were absolutely unfit for any use.

Upon interviewing the manufacturer of these cough drops, and directing his attention to this reprehensible practice, also calling his attention to the manner in which they packed their sponges, I was informed that it was impossible to pack the cough drops in a similar container, as the extra cost of the protecting, transparent cover couldn't be added to the cost of production, for the price charged for these goods was not sufficient to warrant any further addition to it, and competition compelled them to maintain their low price, as the retail druggists would not pay the small extra cost of the more sanitary containers.

Can it be possible that the true cause for this state of affairs lays at the doors of the retail druggists?

Are they not perfectly willing to pay the small extra cost of a cleanly container, if they want to make use of a box for displaying such goods?

I, for one, have refrained from handling these goods owing to the nature of the display container—and it arouses in one's mind a question as to the regard for the rules of cleanliness and hygiene observed in a factory sending out such goods.

It is argued that a large display, in bulk, of merchandise is very helpful in disposing of it. This may be true of certain classes of goods, sold in certain classes of stores, but when retail druggists consider this method of increasing their sales, they must not lose sight of the moral effect such a practice will have upon the minds of the public concerning their professional work, of which their neighbors can only judge by their observations of their commercial customs; and judging from comment made by some of our patrons concerning some proprietors and their methods of conducting their business establishments, the public is becoming more exacting critics of one's method of doing business than we suspect.

Another custom that is followed by a number of druggists is to fill their show windows with a large supply of jelly eggs about the time of Easter, allowing them to remain therein unprotected for weeks. As these goods are somewhat hygroscopic you can well imagine the magnet they make for dust and filth. Just stop for a moment to think from whence comes the material that is deposited upon

these confections, and I cannot believe that you would have any desire to eat any of such sweetmeats were I to offer you some at this time.

The windows have been stated to be the eyes of the store; and, by the public, are considered to be an evidence of the policies that direct the establishment; hence, when confectionery is observed in one's windows that is unfit to be used as a food or confection, what do you suppose is the opinion of the public concerning the remoter recesses of our stores, where their medicines are manufactured, compounded and dispensed?

The advantages of displaying wares in a cleanly manner has been observed by leading manufacturers in many lines of trade, as witness the improved methods of exposing cigars for sale, with their transparent, cleanly cover-plates attached to their boxes, and the display containers that constitute the fixtures of the up-to-date grocery-store.

In a recent conversation with the manager of one of a chain of over two hundred grocery stores, I was surprised to learn how much thought was given to the question of hygienic displaying of goods by the owner. He bids for and receives the patronage of the best class of trade that purchases its supplies at this class of stores—the result being largely, because of less sanitary methods being employed by the other competing chains of grocery stores, in one of which my informant previously labored. He noticed the advantage his present employer has over his competitors, soon after entering his employ, and had learned from customers the reasons why they give their patronage to his present employer.

The proprietor of a well-conducted hennery, appreciates the monetary advantage of a cleanly kept establishment; and the higher price he receives for his eggs if they are perfectly clean, with no evidences of filth or dirt attached thereto, makes him, automatically, an apostle of cleanliness and hygiene.

Inasmuch as we have a reputation as professional men to protect, it is incumbent upon us to take the initiative as business men to practice cleanly methods in displaying merchandise for sale to the public, thereby demonstrating our knowledge of and respect for hygiene and bacteriology; and it cannot fail to have a beneficial moral effect, leading the public to look upon us as a superior class of merchants to whom they will turn when in need of first-class, dependable goods.

I would suggest that we make it an unalterable rule to never sell any commodity to anyone in a condition that we would hesitate to accept as clean enough for our personal use; and if we make this humanitarian decision, we will not display confectionery or cough drops in a container unprotected from dust, dirt and filth.

Were we to view, with a high power magnifying glass, the character of the material that constitutes the dust that invariably is deposited upon all exposed goods, we would hold up our hands in horror, to think that we had been guilty of supplying cough drops and confectionery contaminated by such offensive material.

Kindly remember that the crusade to "swat the fly" resulted from a close study of the material that he carried from place to place, the offensiveness of which was not suspected until science told us the true tale.

Let us demonstrate that we are abreast of the times and prove the fact that we are firm believers in the old adage: "Cleanliness is next to Godliness."

DISCUSSION UPON THE PRECEDING PAPER AND HIGH GRADE CANDY AS A  
SIDE-LINE.—(Printed in September issue.)

MR. C. W. TOBEY:—"The two papers just read are very interesting and useful ones, but that although, as one of the authors said, 'Cleanliness was next to Godliness,' there is one thing I cannot understand about the candy business, and that is, if you take the ordinary candies and put them in a jar with a card stating the price, they will remain there until they are stale; while if you take a hundred pounds of the same candy and expose it for sale in one of these large, open pails, nine out of ten of his customers would say, 'Give me a dime's worth or a nickel's worth.' This shows that cleanliness is not always appreciated. In the cheap stores, where all kinds of candies are exposed to dust more candy is sold, a hundred times more, than is sold in stores that keep goods in a cleanly condition. Sometimes it seemed as though filth was at par. While I believe in sanitary methods, yet the people will buy the goods displayed in pails when they will not purchase those from jars. Therefore, the way to sell the goods is not the sanitary way."

MR. NITARDY:—"I think Mr. Apple's points are well-made and so was that of Mr. Tobey. There is a compromise between the two methods which our firm has adopted. We buy our candy in bulk and then place it in paper sacks priced at five and ten cents. These sacks are printed with the name of the article and the firm's imprint and price. These we place in trays near to the cash-register and when the customer pays his bill, he will often be attracted to them and buy one. We sell a large amount in this way."

MR. FENNEL:—"The public are not discriminating. They see this candy exposed in these cheap, department stores and they think it is good enough, but when they go into a drug-store they expect cleanliness and a better quality of goods."

MR. HOLZHAUER:—"I believe that the candy-business of the future will be done by the drug-store. The tendency is in that direction. Some time ago I placed in my store a wheelbarrow which I filled with horehound drops. The amount of these which I sold was something incredible. I bought them in five-barrel lots and sold tons of them in that winter. The only objection was that when the candy became a little discolored the loss was high, for people would not then purchase it. People not only want to see the candy, but they like to sample it. Concerning high-priced candy the attention of patrons must be called to it. It will not sell itself. Every druggist can make a good business in high-priced candy if he will devote attention to it."

CHAIRMAN MASON:—"It appears to me that the tendency of the last four or five years has been in the direction of higher-priced goods. In many cases it is the attractive package that sells the goods at a higher price."

MR. WEAVER:—"Mr. Mason is right about the package selling the goods in a great many cases. I do not really believe that the candy of the dollar package is much better, but it is more attractive to the young man who is going to present it to a young lady and wants something nice."

MR. APPLE:—"The particular point I wished to make was as to the unsanitary method of displaying such goods. We must not lose sight of the fact that primarily we are pharmacists and are expected to know more about the dangers of exposing goods to contamination. If pharmacists wish to be termed the hand-maid of medicine, we should, in every way, try to show that they possess a knowledge greater than that possessed by the ordinary tradesman. It would doubtless be very easy for a druggist to secure from their candy-dealers pails with a glass cover and this would protect them and keep them in a sanitary condition."

---

## AN OPPORTUNITY FOR DRUGGISTS TO HANDLE INSECTICIDES, DISINFECTANTS, SPRAYS, ETC.

---

E. V. HOWELL.

---

The object of this paper is to present the opportunity of druggists in this line of work, and to lay stress on two points.

First. The commercial advantages of this field of work. Second. To show that *not* to take advantage of this opportunity is a *loss* to the profession in these particulars: First. Loss of the profit that may be derived from this trade; Second. Loss of *other* trade *because* this work, professionally belonging to the druggist, is taken up by others who then naturally add similar products and thus encroach on the legitimate field of trade of the druggist.

The manufacture and sale of insecticides, etc., involving as it does a knowledge of poisons, should be permitted to only those qualified by training and experience to dispense them. The fact that in a large number of cases only a small amount of an insecticide is wanted and that to avoid the trouble in purchasing and preparing this small quantity the public at large is willing to pay a handsome profit to those putting up the ingredients in small packages properly labelled with directions for making, gives the opportunity for *professional work* to the druggist and a profit besides.

For instance, Bordeaux mixture costs about one cent per gallon. If a druggist prepares a small box of powdered blue stone, and a small box of lime with directions for making Bordeaux mixture he can derive a profit satisfactory to himself and to his customer. From the formulas following you can see the advantages of small packages for this line of trade.

As to the second point, the disadvantages of not preparing for this work: In my state (North Carolina) we have to have an exception made in our Pharmacy Act to permit grocers, and general stores to handle non-poisonous domestic remedies. The continual protest of our druggists to this encroachment on their trade is to a large extent the fault of the druggist. First. Because they have not demanded sufficient education and training for their work to *compel* the public to recognize them as a profession. As an example of this fact, I may cite the statement that has been made; that a clerk in a grocery store is as well qualified to handle patent medicines, borax, salts, castor oil, etc., as the druggist with some experience at a soda fountain and four months of hasty preparation for a board examination which he passes, has to handle prescriptions, poisons, etc. This failure to properly train and educate our pharmacists certainly weakens our position in regard to demanding and defining a legitimate field for the qualified druggist.

Again, the druggists in my state neglected the opportunity of furnishing to farmers borax for curing their meat, at a small profit, copper sulphate for soaking their oats and wheat, saltpeter for curing meat, etc., Paris Green for tobacco worms, pepper for preserving hams, etc.

What has been the result? Not only a loss of the small profit on this trade but the serious situation has developed that grocers have quickly added these products together with a long line of allied articles and have thus become entrenched behind a wall of protection—"handles products that his customers expect him to carry."—It is from this fortified position, one given to him without resistance, that many of our druggists wish to dislodge him.

Not until the public is convinced that pharmacy is more of a profession will this effort to dislodge have any degree of success.

Right here it might be well said, that the argument that the drug business is 90% commercial and 10% professional does not annihilate or even affect the proposition of better professional training. The training and examinations are for public safety, and the 10% of this business or the 1% of that, must be safeguarded as rigidly as if all of our business was professional, for the 10% here and the 1% there when added up makes *all* of the part that must be safeguarded.

If the druggist does not attach this line of trade, the tree-doctor, the garden-doctor, the bug-doctor, etc. will arise in your section. He will and has a right to

take this trade if you don't want it. If by your neglect he engages in this work, at least do not then begin to make efforts to restrict, hamper or dislodge him from a field you wilfully or unthoughtfully abandoned. It does harm to your own profession at a late day to attack certain fields of trade that should have been acquired by exploitation, and not reserved by restriction. It is this class of legislative work that meets with resistance although there is merit in the general scope of the work.

It is hoped that these suggestions and the few formulas given will call attention to a line of work that I believe should fall to the druggist professionally and should offer an excellent opportunity for profitable business. In the following formulas, especial attention is directed to the point of putting up each ingredient in small, neat packages of just the amount needed for small operations. A rose bush needs spraying, have a package prepared that makes a gallon or so. The small cost and the convenience in making will attract many to the experiment of spraying the rose. With simple directions for making and a list of diseases and the spray suitable for such diseases prepared, we have an opportunity of doing *professional work* with a *good profit*, resulting in excellent advertising.

## BORDEAUX MIXTURE.

Blue Stone.....	560 grains
Lime .....	831 grains
Water to make.....	1 gallon

Dissolve the Blue Stone in one-half gallon of water in one vessel, slake the Lime in another vessel and dilute with enough water to make half a gallon, pour them together simultaneously into a suitable vessel and a blue solution should be formed.

*Cost.*—Per fifty-two gallons, forty-one and a half cents. Per gallon, four-fifths of one cent.

*Uses.*—Apple Leaf Rust, Apple Scab, Bitter Rot of Apple, Black Rot, Downy Mildew, Leaf Blight, Anthracnose, Wilt, Powdery Mildew, Black Spot Canker, Brown Rot, Fruit Blotch, Leaf Curl, Black Knot, Flyspeck.

## BORDEAUX MIXTURE WITH ARSENICALS.

Bordeaux Mixture.....	1 gallon
Paris Green.....	70 grains

Make the Paris Green into a thick paste with water and add to the Bordeaux Mixture previously prepared. Should be strained before being used.

*Cost.*—Per fifty-two gallons, fifty-two cents. Per gallon, one cent.

*Uses.*—Codling Moth, Common Asparagus Beetle, Cucumber Beetle, Flea Beetle, Pile Worm, Three-Lined Leaf Beetle, Squash Bug, Canker Worm, Gypsy Moth, Plum Curculio, Squash Vine Borer.

## BED BUG KILLER.

Camphor .....	12½ ounces
Paraffin Wax.....	12½ ounces
Rape Seed Oil.....	25 ounces
Benzine to make .....	1 gallon

Mix them.

*Cost.*—Per gallon, 96 cents.

## BISULPHIDE OF CARBON.

*Uses.*—The Black Grain Weevil, Common Bean Weevil, Pea Weevil, Anguimoid Grain Moth, Croton Bug, Fruit Bark Beetle, Grain Weevils.

## KEROSENE EMULSION, WITH WHALE OIL SOAP.

Kerosene .....	85.3 ounces
Whale oil soap.....	2.6 ounces
Water .....	42.6 ounces

Dissolve the soap in the water by the aid of heat, then immediately add the kerosene, make Emulsion by churning.

*Cost.* Per fifty-two gallons, \$3.79. Per gallon, seven and three-tenths cents.

*Uses.* The Harlequin Cabbage Bug, White Grubs, the San Jose Scale, the Scruffy Scale, the Oyster Shell Bark Louse, the Woody Aphis, the Onion Maggot, Apple Root Plant Louse, Chinch Bug, Grape Phylloxera, Grape Vine Leaf Hopper, the Hop Plant Louse, Pear Tree Psylla, Red Orange Scale, the California Live Oak Scale.

## KEROSENE EMULSION, WITH IVORY SOAP.

Kerosene .....	85.3 ounces
Ivory Soap .....	2.6 ounces
Water .....	42.6 ounces

Shave the soap in thin pieces into the water. Heat until the soap is dissolved. Remove the heat and add the kerosene, then churn thoroughly. This makes a 66% Emulsion.

For 10% Emulsion, add  $5\frac{2}{3}$  gallons of water.

For 15% Emulsion, add  $3\frac{1}{3}$  gallons of water.

For 20% Emulsion, add  $2\frac{2}{3}$  gallons of water.

For 50% Emulsion, add  $\frac{1}{3}$  gallons of water.

*Cost.*—Per fifty-two gallons, \$3.79.

*Uses.*—Used for the same insects as Kerosene with Whale oil soap.

## LIME, SULPHUR AND SALT WASH.

Lime (unslaked) .....	6.4 ounces
Sulphur .....	4.8 ounces
Salt .....	3.2 ounces
Water to make .....	1 gallon

Slake the lime, then add the sulphur and salt and heat to boiling.

*Cost.*—Per fifty-two gallons, seventy-eight cents. Per gallon, one and a half cents.

*Use.*—Used in spraying trees before the leaves appear.

## LICE EXTERMINATORS.

Naphthalin .....	3½ ounces
White Wax .....	1½ ounces
Cocoanut oil .....	5¼ ounces
Petrolatum .....	5¼ ounces
Oil Bergamont .....	1½ drams
Oil Cloves .....	1½ drams
Oil Cinnamon .....	1½ drams
Oil Lemon .....	50 minims

Mix the fats and add the Naphthalin, stir until the latter is dissolved, allow to cool, then incorporate the oils.

*Cost* for above formula, thirty-six cents.

## MANGE CURE.

Whale oil .....	100 ounces
Sulphur .....	6 ounces
Tar oil .....	12 ounces
Crude oil to make .....	1 gallon

Shake well and rub once a day.

*Cost.*—Per gallon, sixty cents.

## NAPHTHALIN SOLUTION.

Naphthalin .....	10 ounces
Oil of Lavender .....	16 ounces
Alcohol to make .....	1 gallon

Mix them.

*Cost.*—Per gallon, \$5.07.

*Use.*—A lotion for Mosquito Bites.

## PARIS GREEN AND WATER FORMULA.

Paris Green .....	48 grains
Lime (slaked) .....	48 grains
Water to make .....	1 gallon

Mix the Lime with enough water to make a thin paste and pour into half of the water, stir thoroughly. Do likewise with Paris Green.

*Cost.*—Per fifty-two gallons, eight cents. Per gallon, seven-tenths of one cent.

*Use.*—Army Worm, Asparagus Beetle, Apple Leaf Skeletonizer, Blister Beetles, Bag Worm, Celery Caterpillar, Celery Looper, Celery Leaf Tyer, Cotton Worm, California Devanting Locust, Elm Leaf Beetle, Irish Potato Beetle, Strawberry Weevil, the Cabbage Plutella, the White Cabbage Butterfly, the Cabbage Plusia.

## POTASSIUM SULPHIDE FORMULA.

Potassium Sulphide .....	145.5 grains
Water to make .....	1 gallon

Mix them.

*Cost.*—Per fifty-two gallons, fifteen cents. Per gallon, three-tenths of one cent.

*Use.*—Red Spider.

## RESIN WASH ADHESIVE.

Powd. Resin.....	1 pound
Concentrated Lye.....	3.2 ounces
Fish oil.....	5 ounces
Water to make.....	1 gallon

Place the Oil and Resin in one quart of water and boil until the Resin is thoroughly softened. Dissolve the Lye in a separate vessel and add it slowly to the Resin Mixture, stirring constantly until well mixed. Then add enough water to make the whole measure one gallon. Continue the boiling until the mixture will mix readily.

*Cost.*—Fifty-two gallons, \$3.64. Per gallon, seven cents.

*Uses.*—With a few plants like cabbage and collards which have very smooth foliage, difficulty is often experienced in making poison mixtures adhere and for this purpose this mixture is used.

## RESIN AND SULPHUR SOLUTION.

Sulphur .....	1½ pounds
Powd. Resin.....	580 grains
Caustic soda.....	1 pound
Water to make.....	1 gallon

Mix Sulphur and Resin and make into a thick paste with water. Dissolve the caustic soda in water and add to the first mixture, stir, after boiling ceases and the mixture has acquired a brownish color add half a gallon of water and stir well, finally add water enough to make one gallon.

*Cost.*—Fifty-two gallons, \$5.94. Gallon, nine and a half cents.

*Uses.*—Red Scale, San Jose Scale.

## RESIN LIME MIXTURE.

Resin Mixture.....	7.4 ounces
Milk of Lime.....	19.2 ounces
Paris Green.....	87.5 grains
Water to make.....	1 gallon

Add water to the Resin Mixture and mix thoroughly, add the Milk of Lime and then the Paris Green, previously made into a thick paste with water. This mixture must be freshly prepared when wanted.

*Cost.*—Fifty-two gallons, thirty-six cents. Per gallon, seven-tenths of one cent.

*Uses.*—Cabbage Webworm, Imported Cabbage Worm, Native Cabbage Worm.

## SOLUTION ARSENATE OF LEAD.

Acetate of Lead.....	96.3 grains
Arsenate of soda.....	35 grains
Water to make.....	1 gallon

Dissolve the Lead Acetate and Sodium Arsenate each separately in three ounces of water in wooden vessels, then add water enough to make one gallon.

*Cost.*—Fifty-two gallons, sixteen cents. Per gallon, three-tenths of one cent.

## SOLUTION MERCURIC CHLORIDE.

Bichloride Mercury.....	72 grains
Water to make.....	1 gallon

Dissolve the Bichloride Mercury in about one quart of water by the aid of a gentle heat, then add water enough to make one gallon.

*Cost.*—Per gallon, one cent.

*Use.*—Used to disinfect the knife or other tools in cutting out Pear Blight.

## SOLUTION COPPER CARBONATE AMMONIATED.

Stronger ammonia water.....	1 ounce
Copper Carbonate.....	53 grains
Water to make.....	1 gallon

Make the copper carbonate into a thin paste with water and slowly add the ammonia water, then add enough water to make one gallon.

*Cost.*—Fifty two gallons, \$1.56. Gallon, three cents.

*Use.*—This insecticide is mainly used as a substitute for Bordeaux Mixture upon ornamental plants and maturing fruits as it does not leave the stain that Bordeaux Mixture leaves. It is also inferior as a fungicide.

Destructive to Powdery Mildew.

## SOLUTION AU CÉPESSE MODIFIÉ.

Blue Stone.....	512.5 grains
Ammonia Water, 10%.....	3.2 ounces
Sal Soda.....	1.8 ounces
Water to make.....	1 gallon

Dissolve the Blue Stone in two quarts of water, add the Ammonia water and dilute with water to one gallon and dissolve in the Sal Soda.

*Cost.*—Fifty-two gallons, \$2.60. Per gallon, 5 cents.

*Use.*—This wash should not be used on the foliage of stone fruits and should be applied to other growing plants only with due caution.

#### SOAP SOLUTION.

Laundry Soap..... 6 ounces

Water to make..... 1 gallon

Reduce the soap to fine shavings and dissolve by the aid of heat in one-half gallon of water, then add enough water to make one gallon.

*Cost.*—Fifty-two gallons, \$1.95. Gallon, three and seven-tenths cents.

*Uses.*—Apple Tree Borer, Fluted Scale, Melon Plant Louse, Pear Tree Slug, Red Spider.

#### SOLUTION OF LARKSPUR AND BICHLORIDE MERCURY.

Fluidextract Larkspur..... 8 ounces

Bichloride Mercury..... 28 grains

Water to make..... 1 gallon

Mix them.

*Cost.*—Per gallon, \$1.76.

*Use.*—Crab.

#### SOLUTION FOR ITCH.

Lime ..... 1 pound

Sulphur ..... 2 pounds

Water ..... 1 gallon

Mix and boil one hour, then strain.

*Cost.*—Per gallon, nine cents.

To obtain the best results from the use of a fungicide, it is necessary that it should reach all parts of the plants subject to the attacks of the fungous parasites. Many devices for accomplishing this object are now on the market. All these fall within three principal groups, namely, knapsack pumps, hand pumps, and horse-power pumps. The knapsack pumps are designed especially for low growing crops, such as grapes. The hand-power pumps can be used in a number of ways and if strong and durable are probably the most useful of all the various styles of apparatus. The horse-power sprayers are designed to be drawn by one or more horses and operated by the same means. All these machines must be provided with nozzles that will furnish a mist-like spray and at the same time be easy to clean of any obstruction that may clog the necessarily small opening. There is no form of nozzle that so well fills these requirements as the Vermorel, which is now sold with nearly all spraying outfits. Where good labor is cheap and the crop is mainly grapes and low growing plants, the knapsack form of sprayer will probably be found as economical as any apparatus. For orchard work however, more powerful machinery will be required. Probably the most satisfactory form of apparatus for this kind of work consists of a strong force pump, mounted upon a barrel or hogshead. If mounted upon these, arrangements will have to be made to conveniently draw them through the orchards. The horse-power sprayers are nearly all complicated and expensive, moreover they can not be used satisfactorily under as many different conditions as the hand pumps mounted on suitable reservoirs. They may therefore, be dismissed with the statement that it is only in exceptional cases, as, for example, in case of an orchard of several hundred acres on level ground, that it will pay to use them.

With reference to the cost of the several kinds of apparatus mentioned it may be said that good knapsack pumps, complete in every detail may be obtained at

\$10 each. The cost of a first-class orchard outfit should not exceed \$25. Some kinds, in fact, may be fitted up for \$10 or \$12.

There are many farmers and many others who grow a miscellaneous line of fruits, such as a few grapes, pears, apples, etc.; in such cases it is desirable to have an inexpensive and effective apparatus that will answer for the various crops. The hand-pump which consists of a small force pump provided with a long piece of discharge hose and a cyclone nozzle. The whole outfit can be purchased and put together for \$5, and will be found in every way superior to the many forms of syringes on the market. The pump is strong and durable and although small, it will throw a solid stream, the size of a lead pencil, for more than thirty feet. It may be used for trees of all kinds, as well as for vines and low growing crops.

I have clearly shown the preparation, use and cost of some of the most important insecticides. We know that insects do untold damage to the fruit and vegetable crops of practically every farmer in the country. Having shown that the cost is practically nothing and if insecticides are used they will save the farmers of the country a vast amount of money each year, it clearly follows that insecticides should be put within the reach of every farmer, and it seems to me that the druggists as a side-line and almost a part of his business is the one man above all others to supply this vitally needed remedy for the farmer. This naturally falls within the scope of the druggist and if he will avail himself of the opportunity of thus aiding the agriculturist, he will receive an abundant return.

---

### THE ADVERTISING METHODS I USE.

---

HAROLD N. BRUN.

---

It has been said, "the merchant or manufacturer who fails to advertise is very much like the bashful beau who throws his best girl silent kisses in the dark. He may know what he is doing, but no one else does." To know what one is doing is necessary, but to know why one is doing a certain thing, is of great importance.

In discussing my advertising methods, I will not dwell long upon the methods themselves as they are neither new nor original, but will endeavor to tell you my reasons for using them, which I believe will be of more interest to you.

I am located in a foreign neighborhood in a large city. A large percentage of my customers are illiterate. They are working people, employed in shops, factories and in heavy work. The average income of the family, according to J. W. Jenks and W. J. Lanck, in "*The Immigration Problem in the United States*," is about eight hundred dollars a year. Their needs are simple.

*The Problem*.—What kind of goods are these people using now? What class of goods do they not use, but should use? How can I command their attention and interest them in my wares?

*The Drug Store Paper*.—This I use for the following reasons: The children of the foreigner attend school and the older people are eager to advance their

knowledge of the English language. These people do not subscribe for magazines and will more carefully peruse the drug-store paper, than the average American who devotes his time to reading the weekly or monthly publications containing stories by highly paid authors.

*Window Displays:*—These that attract attention require considerable thought and study. The average person goes along engrossed with his own thoughts and it takes something unusual to divert his mind from himself to the windows. We spend considerable time on this feature of our advertising.

*Gifts:*—At regular intervals we give away, with every purchase of twenty-five cents or over, a gift of some sort, usually a small bottle of perfume. This creates a feeling of friendliness and good-will.

*Personal Advertising:*—The biggest factor in dealing with this class, is what I would term, personal advertising. By this I mean the treatment of the customer while in the store. People who are ignorant and often poorly-clad, seldom receive courteous attention, therefore they appreciate it all the more when they do. We try to make our customers feel at home and treat them with consideration. I have impressed upon my clerks, that it is the customer who pays their salaries, the rent and my profits.

*Special Methods:*—One of the things my customers need, but few use, is a good tooth brush and a tooth powder. To acquaint them with their needs in this direction, I have printed small slips of paper in three languages, English, Polish and Italian. I dwell upon the necessity of keeping the teeth clean in order to preserve them, and save dental bills. By this means I am rendering them a real service and at the same time promoting the sale of my goods.

I believe in specializing on one preparation or product. In having something a little better than any one else, if possible. I give special care to the handling of cod liver oil, importing it direct from Norway. I see to it that it is always fresh and sweet. This I advertise as a leader, not in price but in quality, in the Scandinavian papers.

As you see my methods are neither new or startling, but I trust that my paper will be of interest to those engaged in the drug business under similar conditions, or to those engaged in the drug business under different conditions who have made a study of their possibilities.

---

## WHAT IS YOUR BEST PAYING SIDE LINE?

---

FRANK RICHARDSON.

---

My best paying side line was for a long time taken as a matter of course and not much attention paid to it.

But after a time my attention was called to the possibilities in the cigar department, and I began to take notice, purchased a first class case with lots of moistening surface and a hygrometer, to keep me informed as to the condition of the atmosphere in the case.

Care was taken in selecting first-class brands at the various prices, and then we got behind the goods and began to "boost."

We were careful to keep the moisture in the case between 60-65 degrees, keeping the case tightly closed when not in use, consequently the stock is always in perfect condition and now we have the reputation of being the only store in town, whose stock is not all dried out during the winter time, this, of course, has helped the trade greatly and the cigar department has grown until it is the best paying side line in the store, doing nearly three times the business it did before. During the winter months, when your store is heated by artificial heat, cigars and tobacco must be watched very carefully and a certain degree of moisture (60-65) maintained in the case constantly, lest your stock dry out, lose its flavor and your trade go elsewhere, where the stock is properly kept.

I figure that my cigar department pays my rent, light and heat, and that is doing pretty well in a town of 1600 with 15 places selling cigars and one cigar manufacturer.

Too little attention is paid to this department in the average store, the stock is purchased, placed in the case and no further attention given it except to hand out the goods when called for.

Cigars are very sensitive to artificial heat and quickly dry out and lose their flavor and can not be brought back to their original condition. A little thought and attention will prevent this. In the first place get a good tight case, with plenty of moistening surface, place a hygrometer in it, and then see to it that the moisteners are filled at least once a week or as often as the hygrometer falls below 60 degrees, and keep the case tightly closed when not selling from it.

Have variety enough to suit all classes of customers, and endeavor to learn the likes and dislikes of your customers.

When you put in a new brand show it up and pass out enough samples to start a demand for it.

In a community such as the one I live in, special sales and premiums do not pay, but by careful attention to keeping stock, giving good value, and a pleasant word to the customer any one can largely increase the trade in this department, without adding to the expense account.

---

## EFFICIENCY AND A NINE HOUR DAY.

---

C. A. WEAVER, PH. C.

---

In taking up this subject of shorter hours for the Retail Druggist, I have been led to believe, from an experience of some twenty-eight years, behind the counter, that the working of long hours was an unnecessary hardship that could be easily avoided.

This paper is written from the view-point of the so-called "two-man" drug store, comprising a registered proprietor, and one registered clerk, which I believe, constitutes about 60 per cent. of all the drug stores of the United States—stores doing a business of from fifteen to thirty thousand dollars a year. The smaller amount representing the two-man store, with the limited territory and

little effort, and the twenty to thirty thousand dollars, the busy, "get-there" store, with a larger field, and a more pronounced effort to build up trade.

Starting some twenty-eight years ago, as errand boy in a drug store, I naturally inherited the then prevailing hours of 7 a. m. to 10 p. m., with one night and one afternoon or two nights and part of every Sunday off.

It seemed only natural to fall into this rut, as all drug stores were conducted on very much the same plan and any scheme for shorter hours at that time would have been pure heresy.

My experience of the first eighteen years resulted in my coming to the following conclusion, that the drug business with its long, nerve-wracking hours, was not worth its remuneration, especially if a probable loss of health were considered.

It was quite natural then, at this time that I decided to forsake the retail for the manufacturing end of the business, the latter offering every opportunity for the continuation along lines of work, for which my education had prepared me, at the same time diminishing the hours of labor to a point where rest and recreation, so absolutely necessary to a man's health and efficiency were in evidence.

Despite the fact that the relief from long hours was fully obtained, after one year I accepted a position as manager of the store in which I had formerly clerked, having come to the conclusion that the retail drug business offered a greater opportunity, over the manufacturing, for the individual, and with the firm conviction that a scheme of hours could be evolved in which greater results would be obtained by concentrated effort, over a period of eight or nine, rather than a weakened effort extended over fifteen or sixteen hours, as formerly.

At this time I was fortunate in having the services of a very good clerk, who felt very much as I did in regard to the long hours devoted to the accomplishment of a given amount of work. So after considering the requirements of our store, we decided the work could be done to better advantage in shifts averaging about nine hours each, sometimes a little more, sometimes a little less. One week the clerk opening the store at 7 a. m., having one and a half hours for dinner, and leaving at 6 p. m., myself coming on at twelve, noon, having one hour for supper and closing at ten p. m.

We also worked but six days a week—one week having all day Saturday and the next week, all day Sunday off. This was the only hardship that went with the arrangement, as it necessitated having our meals in the store one day each week, but as it gave us one whole day for recreation, we were glad to overlook this slight discomfort. This Saturday and Sunday work has been varied and changed from time to time up to the present moment.

This scheme of hours was continued for some seven years, and still appeals to me as the more desirable one, as the hours of labor are continuous. Individual requirements, however, necessitate various modifications, for instance at the present time, we are working in divided shifts—one man working in the forenoon and evening of one day and the morning and afternoon of the next day, which gives each man every other afternoon and every other evening off. This plan, like the preceding one, provides for about nine hours in the store each day and has been in operation the last three years.

To say the original scheme was a success is putting it mildly. It was a pleasure to see that clerk come in at noon of the days he was to work the late

shift—to see him get into his store coat, and then notice the work fly. It disappeared like magic. This man was not tired out, he was not filled with the toxins of fatigue—he was “Johnny-on-the-Spot”—he had a new toy—he had the pleasure of labor, with the time for play coming, also the time for rest, and plenty of it in sight.

The clerk and I knowing it was a test case, naturally started out to make it a success, and we did. The work of the store was never so well or quickly done. Detroit at this time was just on the rise, and our business grew by leaps and bounds, without seemingly to disturb or very much overwork us at any time.

Efficiency is the order of the day. It is not how long we work, but how much we accomplish in a given time. I believe a man can do about so much work in a day, and from experience, believe this amount can be accomplished in eight or nine hours of industrious labor. If your labor be extended over a much longer period, a slowing down, a lack of “pep” and a general loss of efficiency will follow.

For a time the work *may* be done, and possibly as well, but at what a foolish cost, when at least one-third of the time might have been spent away from the store.

To-day, when I hear a druggist complain of the confinement and long hours of his business, I know he must be at fault personally. He either does not work long hours, or applies himself only half-heartedly, at the time he is supposed to be on duty. The latter is undoubtedly the main trouble. He has no regular hours for himself. He comes and goes when he pleases and is only governed by the clerk's time off. The store is on his mind when he is not there and he thinks he is working. Let him get right down to “brass tacks” for he is not “delivering the goods.” He could not work for anyone else in the slipshod way he works for himself, and what excuse a man can offer for giving himself poorer service than he would render others, is “too deep” for me.

Give yourself and your clerk the benefit of shorter hours and then see that you devote those hours entirely to work. *You* are the one to set the example for your clerk—you are the measure by which he plans his work.—Set him an example by being prompt and industrious in your hours of labor. Visiting, standing around unoccupied, reading the newspapers, etc., never brought a man anywhere in this world of business, with its keen competition demanding your attention every minute. Hustle a little—get all the work finished for once and strive to keep it so, by systematic effort. The appearance of your store resulting in more and better business, will repay you beyond your fondest expectations.

That the unfavorable impression too often given customers by a clerk or even a proprietor, in grudgingly leaving a story or magazine, to half-heartedly wait on them, should be eliminated entirely from our stores, there can be no question, and undoubtedly shorter hours is the solution. Read more, play more, rest more away from business, but work more, strive more, accomplish more during your hours of labor.

Druggists may argue that locations of their businesses, etc., may make this short hour scheme out of the question, but my contentions to the contrary are based on the fact that my personal experience covered two neighborhoods vastly different from each other, and in each the resulting success was the same.

Many imaginary obstacles may arise, in the minds of the individual, as he endeavors to apply the shorter hours to his own business, but experiment will convince the most skeptical that this is one of the problems of the drug business that can be most easily solved.

In summing up, I would have you thoroughly appreciate the fact, that this is not merely a suggestion or theory, but my personal experience of short hours in the past ten years of my business life.

Any druggist can demonstrate the practicability of shorter hours to his entire satisfaction, if he will but make a determined start, necessarily with the co-operation of his clerk and help in general, along the lines of systematic labor.

Isn't it really worth the while when a better-kept, and "up-to-the-minute" store naturally producing more business, is the result, while at the same time, health and recreation are not sacrificed, but on the contrary, are a direct outcome of the whole scheme?

Surely you will find that much of the weariness and dissatisfaction with our work, which we as employers experience, and much of the unrest and shifting around of our clerks will disappear.

---

#### TREATMENT OF WOUNDS IN WAR.

A striking fact observed in the treatment of wounded in the present war, whether on land or sea, is the great prevalence of sepsis. In the author's own experience, all the wounds he had seen so far were septic, some of them very badly so. Tetanus and acute spreading gangrene are also common, though tetanus has not yet been seen in the naval wounded, and this can be understood when it is remembered that the tetanus bacillus reaches wounds from the soil. The prevalence of sepsis in the large wounds is possibly to be accounted for by the length of time which may elapse after the injury before the patient comes under treatment. As to the treatment of this class of wounds, the author lays it down as an axiom of practice that if the treatment can be carried out within the first twenty-four hours (and, in the case of wounds soiled with earth, forty-eight hours) an attempt should be made to kill the organisms which have entered the wound. For this purpose, chemical antiseptics are probably the only means available, and in this connection there are two important points to be taken into consideration—namely, to kill actively-growing bacteria, and also the spores of bacilli. A saturated aqueous solution of carbolic acid (1 in 20) will kill naked, actively growing bacteria in a few seconds, but will not kill spores with certainty under twelve to fifteen hours. Liquefied carbolic acid, however, will kill spores in a very few minutes, and this must be used for wounds soiled with earth. Carbolic acid is an anæsthetic, and its application causes very slight pain, which subsides almost immediately. But iodine, though practically of the same antiseptic power as carbolic acid, has a number of disadvantages, one of them being the great pain it causes, this lasting for a considerable time. Therefore, the author prefers carbolic acid to iodine not only for the disinfection of the skin, but also, and more especially, as a means of destroying the bacteria which have already entered wounds before they come under the care of the surgeon.—*Sir W. Watson Cheyne, Bart.* (*Brit. Med. Journ.*, November 21, 1914, 865).

## Section on Practical Pharmacy and Dispensing

Papers Presented at the Sixty-Second Annual Convention

### ASSAYING GALENICALS.

JEANNOT HOSTMANN.

At the Nashville meeting, the writer contributed a paper on "The Necessary Apparatus in a Retail Pharmacy,"<sup>1</sup> which did not create much discussion. Since then, it has been both praised and criticized. Very little praise emanated from retail pharmacists but quite some criticism. The praise was usually bestowed by men not actively engaged in the retail business.

At the annual meeting of one of the state associations, the writer heard a member criticize the enforcement of the "Food and Drug Law" or rather laws, and was surprised when the statement was made that if retail pharmacists attempted to assay and standardize their drugs and preparations, the cost would be prohibitive.

"Are we druggists supposed to spend a thousand dollars for the equipment of an analytical laboratory, and then spend twelve hundred or more dollars per year to hire a chemist to run it for us?" This was his query. He did not, as I do not believe any progressive pharmacist would, deny that assaying and standardizing were absolutely necessary to the welfare of our profession; he simply, like many others, seemed to think it more important to attempt to standardize the price of "Brown's Cureall" than to raise pharmacy to a professional level in the eyes of the physician and layman by actually assuring himself by tests made in his establishment that the drugs he was selling and dispensing were really as represented.

Several papers have been read at various meetings during the current year, discussing the separation of the professional pharmacy from the commercial drug store. A paper will be read at this meeting in which the author recommends the formation of a national association of prescriptionists. All this shows the trend of thought of many thinking pharmacists, which no doubt will sooner or later bear fruit in placing pharmacy where it belongs, viz: A profession, whose first thought will always be to save human life and alleviate and prevent human suffering.

Martin L. Wilbert, in Reprint No. 189 from the Public Health Reports, after showing a summary of adulterated and sophisticated drugs collected during the time of one year, calls attention to the duty of pharmacy as follows:

"In conclusion it may be reiterated that the more evident shortcoming in the present-day enforcement of pure-drugs laws is the general failure to properly place the responsibility for the nature, kind and purity of the medicines supplied

<sup>1</sup>J. A. Ph. A., 1914, 697.

to the consumer where it belongs. This shortcoming is being corrected, to some extent at least, by recently enacted laws to regulate the practice of pharmacy by placing the responsibility squarely on the person dispensing the drug.

"The proper enforcement of laws designed to regulate the practice of pharmacy in conjunction with pure-drugs laws, should relieve physicians and the public of any doubt as to the composition, purity, quality and strength of all drugs and medicinal preparations used in the treatment of disease. As these laws are enforced at the present time it is plainly evident that the methods of control are inadequate and do not serve to safeguard public health as well as they could or should.

"Boards of health and other State and Federal officials intrusted with the enforcement of these laws should endeavor to call attention to the desirability of having druggists exercise a close scrutiny of the drugs and preparations included in their stock, to keep drugs, chemicals and preparations in suitable containers, to throw away old useless material, and to see that scales, weights, and measures are reliable and accurate under the conditions imposed upon them.

"Some effort should also be made to see that drug stores are equipped with the necessary analytical apparatus with which to analyze or examine all supplies and thus assist in maintaining a more efficient control of the articles sold as medicine.

"Consistent and efficient control of the identity, purity and strength of all drugs and preparations as furnished the consumer would make for progress in the science of medicine and should prove to be an important factor in promoting public health."

The United States Pharmacopœia presents the tests in such a way that any pharmacist who is a graduate of any good college of pharmacy and cares to employ the knowledge that he has gained as a student will have no trouble in determining whether the drugs and chemicals he purchases and dispenses and the preparations thereof, are up to standard.

If the pharmacist is a graduate of a college of pharmacy where pharmacy is taught as it should be, and employs only such graduates in his Prescription Department, he will not have to hire any chemist to attend to this class of work although it may be necessary for him or his employee to spend some of the time now spent in dressing windows, etc., in the laboratory.

The false ideas as to cost of equipment caused the writer to compile the following table which embraces the most important utensils needed to perform the necessary tests:

## INVENTORY OF EQUIPMENT AND COST.

Volumetric Flasks.		
2	100 cc. ....	.60
2	250 cc. ....	.80
2	500 cc. ....	1.40
<hr/>		
2	files—rat tail .....	.20
2	files—triangular .....	.20
2	lbs. rubber stoppers .....	3.00
3	lbs. glass tubing .....	1.00
Flasks.		
2	60 cc. ....	.20
2	125 cc. ....	.25
2	250 cc. ....	.35
2	500 cc. ....	.40

2	porcelain crucibles with covers .....	.50
3	triangles .....	.15
2	funnels—2" .....	.15
2	funnels—3" .....	.20
2	packages filters .....	.50
a	pycnometer .....	1.00
a	test tube rack .....	.50
1	dozen test tubes .....	.25
a	Bunsen burner .....	.30
3	ft. rubber hose .....	.25
2	100 cc. beakers .....	.20
2	250 cc. beakers .....	.30
2	3" evaporating dishes .....	.24
2	2" evaporating dishes .....	.20
2	60 cc. separatory funnels .....	1.50
2	125 cc. separatory funnels .....	2.00
1	water bath, 6" .....	1.25
2	burettes, 50 cc. in 1/10 with glass-cock .....	3.00
2	pipettes, 1 cc. .....	.15
2	pipettes, 2 cc. .....	.15
2	pipettes, 3 cc. .....	.20
2	pipettes, 5 cc. .....	.25
	Oven .....	5.00
	Desiccator .....	1.00
	Pt. Foil .....	.75
	Pt. Wire .....	.30
	Glass Rods .....	.15
	Microscope .....	75.00
	Balance .....	20.00
	Weights .....	3.50

Thus you will see it will cost about twenty-five dollars to buy the most necessary utensils, if the store is not equipped with a good balance, and many are not, why then twenty-five dollars more will buy the balance and weights from one milligram to one hundred grams. An oven and desiccator will cost six dollars more and, finally, a good microscope can be purchased for seventy-five dollars.

This comparatively small outlay will repay the pharmacist, who intelligently and faithfully uses the outfit after installation, many times over financially, as well as otherwise.

*Columbia University, College of Pharmacy.*

---

The value of the exports of perfumery to the United States from the consular district of Nice, France, decreased from \$1,578,228 for 1913 to \$755,671 for last year.

## Editorial

ERNEST C. MARSHALL, Acting Editor.....63 Clinton Building, Columbus, Ohio

### COMMERCIAL PHARMACY.

THE address of Governor Hammond of Minnesota at the meeting of the Minnesota Pharmaceutical Association, which appears in this issue, is most timely and interesting.

It should be read thoughtfully by every member of the profession.

As one entirely outside of our circle, he pleads with us to hold fast to the high standards it has always maintained and not to allow it to become entirely commercial. Mark you, this is not a cry from the past; from an old-time pharmacist, who wishes to see the profession restored to old ways and old manners. It is from a man of the present day; one not particularly in love with the past, but who is in immediate touch with the present, who has his eye to the rising sun. He tells us that commercialism is simply a cry for the dollar. That it is unworthy of us, and that we should strive to get away from that thought and build our profession upon broader and better lines, the lines which have brought to the name of Pharmacy dignity and honor.

It is almost to our shame that such counsel should be made to us from outside. Are we not intelligent enough to grasp the situation for ourselves? Has the time arrived when we cannot see the drift of things with our own eyes? Have we not wit and wisdom enough to appreciate the sacrifice of all that makes Pharmacy noble?

The opinion of Governor Hammond cannot be taken as a single view of a careless observer. It is the concrete expression of the opinion of the mass of the people. What he has said to us plainly and directly, the world is thinking and saying of us. The people are observant of the change in Pharmacy and they deplore the retrogression of the profession from a science to a business. No one who is good at heart but regrets and mourns at the self-ruin of a man;—then how much more would they mourn at the degradation of a class of men, who have advanced the world by their work along scientific lines.

It was not, and it is not necessary, to sink the scientific side of our profession in order to lift the commercial side. The latter has its place in our profession,—that no one will attempt to deny. But there is no need to sacrifice the art of Pharmacy, its very soul and inspiration, entirely to the commercial side.

As heartily as any one could desire we would like to see all pharmacists successful commercially, successful financially, all of them wealthy. But we cannot think that in order that they should be successful commercially, that they need to declare themselves non-professional, to relegate all the fixtures and stock which from time immemorial have marked the pharmacy, to a back-room limbo, and display only the articles belonging to the commercial side of the business; in fine, to

banish from sight all that makes a pharmacy distinctive, and to display only those goods sold in common with other stores without peculiar character. To deliberately throw away their scientific reputation and place themselves in open competition with other merchants who are without any technical training.

Develop the business instinct to its full, but do not sacrifice what is a valuable asset to you in so doing.

The sale of biologicals is more profitable than that of cameras or post-cards or magazines, and in that field there are fewer competitors, and in the handling of such articles you will make yourselves of more worth to the world and to your profession, and separate yourselves from the common business man.

Not that this will make you better than the common man,—not at all. Knowledge makes no man a better man than another. What one man knows more than another in one line, is compensated by what the other knows in another line. You can dispense a lot of quinine pills to a blacksmith, which it is impossible for him to make, but he can forge steel which you would find it impossible to accomplish. He can temper the spatula you use in making the pills and you cannot. So that the average of knowledge is in balance between you. That is his trade, and yours is that of a pharmacist, and as he is of value as a blacksmith and by reason of his knowledge of temper, of iron and of steel, of forging and of casting, so you are of value the more you know of drugs and chemicals, of percolation of solution, of compatibles and incompatibles. Commerce, yes, admit it all you please along your own line. Know whence your stock comes, its impurities, its adulterations, keep step with your rank, and be a PHARMACIST. In that way you will elevate and raise the profession of Pharmacy and make yourselves better, wiser and wealthier men.

### THE NATIONAL INSURANCE ACTS OF GREAT BRITAIN.

THESE acts (1911-1913) for information regarding which we are indebted to the Chemist's and Druggist's Diary, are to provide insurance against the expenses of sickness and loss of wages from unemployment, by persons earning not more than £160, (\$800.00) a year.

It is, in effect, a compulsory insurance, to whose funds the employer, the employe and the government contribute; the employer paying from 3d. to 6d. (6 cents to 12 cents) a week; the employe from 1d. to 4d. (2 to 8 cents) weekly, while the government pays two-ninths of the male benefits and one-fourth of the female benefits and in addition defrays all expenses of administration.

All workers employed are required to join an approved Friendly Society, of which the Chemist's Friendly Society is an example.

These societies furnish to their members a card upon which are spaces for the affixing of thirteen stamps. The employer is required to affix to this card every week a stamp, to show that the owner of the card has paid his assessment and the employer is authorized to deduct from the employe's wages the amount of the stamp.

The benefits paid in Britain are:

MEN.

1. Medical benefit; that is free medical attendance and medicine, or a money payment.
2. Treatment in a sanitarium in case of consumption.
3. Sick benefit; 10s. (about \$2.50) a week for 26 weeks.
4. Disablement benefit; 5s. (\$1.25) a week afterward if still incapable of work.
5. Maternity benefit; 30s. (\$7.50) for wife on confinement.

WOMEN.

1. Medical benefit, as for men.
2. Sanitarium.
3. Sick benefit; 7s. 6d. (\$1.87) a week for 26 weeks.
4. Disablement benefit, as for men.
5. Maternity benefit; £2 (\$10.00) unless husband is insured. She is paid a sick benefit also after confinement.

The Medical Benefit comprises medical attendance and treatment, with provision of proper and sufficient medicines, and such appliances as are allowed by the Insurance Commissioners.

Every registered medical practitioner is entitled to admission as a panel-doctor and insured persons may select as their attendant any physician upon the list, within the area in which they reside.

Unless the insured person resides more than a mile from the nearest drug-store, the doctor does not supply the patient with drugs or appliances. For the supply of these, the Insurance Commissioners contract (1) with registered chemists and with limited companies, (recognized by the Poisons and Pharmacy Act, 1908,) to dispense prescriptions and to supply drugs and appliances; (2) with other persons to supply drugs and appliances, and (3) for the supply of appliances only.

To every panel-chemist is supplied a Drug Tariff or price-list of the charges he is entitled to make. This costs him 6d. (12 cents). It states (1) the prices he may charge for quantities from one-half grain or minim to one ounce of each article; (2) Names of articles whose cost is subject to fluctuations on account of the war, the prices of which are fixed monthly by agreement between the British Medical Association and the Pharmaceutical Society; (3) Rules for calculating prices not fixed by the Tariff; (4) Dispensing charges, and (5) Notes for dispensers.

The rules for calculating prices not fixed are very precise. For solids purchased in half-pound quantities or more, the pound cost is taken and divided by eleven, and this gives the Tariff charge for one ounce. This amount is divided by seven to find the charge per drachm, and that amount by fifty to find the charge per grain.

In the case of drugs purchased in small quantities (avoirdupois ounces), four-tenths of the cost is added to find the Tariff charge for a troy ounce, and this amount is divided by seven and the quotient by fifty as before, to ascertain the charge for a drachm and a grain.

For liquids, such as Tinctures, etc., where the sp. gr. is not greater than water, the listed price is divided by twelve, to get the tariff for one ounce; that, is divided by seven to ascertain the tariff for a drachm and that, by fifty to find the charge for a minim. For heavier liquids, such as Syrups, etc., the divisors are 9-7-50, respectively.

Dispensing charges are allowed upon all liquid preparations prescribed for internal or external use as medicines, but, in some districts, dispensing charges are not

allowed for extract of malt, fluid magnesia, glycerin, lime water, turpentine and certain fixed oils; nor is an emulsion fee allowed for cod liver oil or petroleum emulsions.

The dispensing charges allowed are as follows:—For preparations up to eight ounces, 2d.; over eight ounces, 3d.; Stock mixtures, one-half this amount; for pills, capsules, lozenges or tablets not on tariff, for one dozen, 3d. (6 cents); and for each dozen or fraction of dozen extra, 1d. (2 cents).

For powders 1 to 6, 2 pence; 7 to 12, 3 pence; and for each dozen or fraction of a dozen extra, 1 penny; if placed in cachets, 1 penny a dozen extra. Suppositories, pessaries and bougies, not on tariff, for one-half dozen, 4d. (8 cents); a dozen, 6d. (12 cents).

A fee of 1 penny (2 cents) each is allowed for copying prescriptions. The charge for containers is fixed at 1 penny to 3½ pence, and these amounts are to be deposited by the insured person and refunded to him when the container is returned.

If a prescriber fails to justify himself in prescribing in an unnecessarily expensive manner, the excess cost of such prescribing is deducted from the next payment made to him. Extravagant prescribing may consist of (1) expensive items; (2) high general average cost of prescriptions, and (3) high average number of prescriptions per insured person.

Physicians are allowed to dispense only in emergencies and in such cases he is allowed 6d. (12 cents).

It is to be noted that the Board of Customs and Excise permit chemists to dispense methylated spirit in liniments or lotions prescribed by panel-doctors, the Panel Regulations stating that "When aconite, belladonna, soap and compound camphor liniments are ordered on National Insurance forms, methylated liniments are presumably intended and should be supplied."

When Aqua is ordered without further qualifications, ordinary water is to be used. If proprietary galenicals or chemicals are ordered they must be dispensed, —no substitutions are allowed.

The amount of compensation paid physicians seems to be largely in excess of that paid to druggists. The statement is made in the *Pharmaceutical Journal* that a physician having 1000 patients on his Panel will receive £300 (\$1500.00) a year for his attendance.

The committees in some cases seem to be unable to pay the bills of the chemists promptly. One druggist informed the Glamorganshire Insurance Committee that unless they paid him his bill amounting to more than £100, (\$500.00) he would be obliged to file a petition in bankruptcy, and in Liverpool it is reported the chemists are likely to have to face a deficit of about £5000, (\$25,000.00) and in London the estimated deficiency was about £46,000, (\$230,000.00).

From many of the other districts the reports were not favorable as to the operation of the laws and in most districts the payment of bills had been deferred.

Some trouble would appear to have developed in pricing accounts also, for in one of the *Journals* appear two advertisements of persons who will assist druggists to price their prescriptions properly.

It may fairly be presumed that under the regulations of the insurance act, none of the Panel Chemists of Great Britain will become millionaires from the results

of their activities under this act. The allowance for dispensing seems exceedingly low in all cases.

American druggists would not care to dispense two dozen powders for eight cents, or to make a dozen suppositories for twelve cents. Just what our British *confreres* think of the operations of this insurance is shown by the following communication to the Pharmaceutical Journal and is interesting, for it is possible that some of our legislators may attempt to introduce some such legislation into this country or into some of its political sub-divisions.

"But what does the pharmacist get? Suppose he receives a prescription for bicarbonate of soda—two drachms (he must know how this is prepared and what are the possible impurities); Liquor Bismuthi, four drachms (he must be acquainted with the method of preparation, with pharmacopœial doses, and with the principles of pharmaceutical testing); tincture of nux vomica, one drachm (the poisons schedule must be at his finger-tips, and the processes of maceration and percolation, and the use of different strengths of alcoholic menstrua must all be known to him; the extraction of alkaloids and the natural order, habitat, and properties of medicinal plants form a further part of the knowledge he must possess in order to practise his simple duties); syrup of orange, half an ounce (how many different kinds of sugar are there? How are they distinguished and how is the specific gravity of a liquid obtained?); infusion of gentian, to make six ounces (how is an infusion made and how does it differ from a decoction?). This simple process of dispensing also involves other questions, such as standards of weights and measures, the translation of Latin names and directions, incompatibilities, dosage, etc., etc., and when the pharmacist has completed his work, exercised his skill, and supplied the insured person with a bottle of medicine correctly compounded *secundum artem* he receives as a reward, in addition to the cost price of the ingredients he has used, the magnificent sum of twopence. Shade of Galen! It reminds one of the urchin who restored a lost article of considerable value to its owner and received in return a halfpenny, with the injunction, 'For heaven's sake don't go and make a beast of yourself!'"

#### HENRY H. RUSBY, M. D.

Dr. Rusby was born in Franklin, N. J., April 26, 1855. His father was a country merchant of that place and in its primary and grammar schools young Rusby began his education.

When he had reached the age of twelve years, his father gave up business and retired to a farm, where the son assisted him in the agricultural work. Having ambition to become educated he exhausted the capacity of his home district for education and then went to Massachusetts where he attended the Westfield Normal School of that state. He then entered the Centenary Collegiate Institute of Hackettstown, N. J. After graduation from this institution he became a teacher at Roseland, N. J.

While occupied in pedagogical work he used his spare time in the study of Botany, and he made an herbarium which contained nearly all the flowering plants and ferns of Essex county. This was exhibited at the Centennial Exhibition of 1876 and gained for its maker a medal and a diploma.

In 1880 he was an agent of the Smithsonian Institution and roamed New Mexico for eighteen months in its service. In 1883 he was engaged by Parke, Davis & Co. to study the medicinal plants of Arizona. In 1884 he was sent by them to South America to study the coca industry, cocaine just then coming to the front as a remedial agent of value. He crossed the continent of South America from the Pacific to the Atlantic, taking eleven months for the trip. It was on this trip that the medicinal value of Cocillana was first brought to light. He brought back from this trip 45,000 specimens, representing some 4,000 species, a fifth of which were previously unknown to botanists. On his return to New York he submitted a plan to the Pan-American Medical Congress for a systematic examination of American Flora, which plan was adopted and Dr. Rusby became the Chairman of the Commission appointed to do that work.

In 1896 he explored Venezuela for botanical specimens and made a large collection of plants. In 1888 Dr. Rusby became Professor of Botany, Physiology and Materia Medica in

the College of Pharmacy of the City of New York, and in 1898 he assumed the Chair of *Materia Medica* in the Bellevue Medical College.

He has contributed largely to botanical literature and was one of the active promoters of reform in botanical nomenclature, upon which his name is indelibly impressed by the fact of its use as *Rusbyi* in the formation of many titles of plants. He wrote the monograph on *Cinchona* for the United States Dispensatory and besides other writings he has published several books, among which is his *Manual of Botany*. He is also one of the authors of the *Standard Dispensatory*.

In all of his eminent labors as a botanist and a pharmacologist Dr. Rusby has been handicapped by defective eyesight, a fact which was not recognized until he became a medical student.

In 1906 he became the expert adviser of the Department of Health in New York and in 1907 he was appointed Pharmacognosist at the port of New York. In this work he has encountered much opposition and misrepresentation regarding which Dr. Rusby says:—

"Had we not been interfered with by others, there would at no time have been any occasion for antagonism on the part of any portion of the drug trade, unless there had been some one who was determined to defy or evade the plain intent and provisions of the law. When it became clear to me that a conspiracy existed between certain adulterators and misbranders without and some others within the Department of Agriculture to misrepresent Dr. Wiley and to destroy his reputation, as a necessary preliminary to destroying the efficiency of the law, I communicated the facts in my possession to President Roosevelt, which act ultimately frustrated the projects of the conspirators. This action I took alone, and quite without the knowledge of Dr. Wiley or anyone else in the department. Nevertheless, it was assumed by the enemy that a number of us were associated in the procedure, and each of us was marked for destruction.

"The following incident will serve to illustrate in part the methods employed to accomplish this end: In my letter to the President, I had gone fully into the views of Dr. Kebler and myself as to the proper treatment of importers and dealers. I explained that it was our view that when the purpose of the law and intent of the Department were fully understood, the trade generally would not only meet the requirements but would interest themselves in the work of reform and would coöperate with those conducting it. We therefore held that it would be neither just nor wise to try to see how many offenders could be caught and punished, but that our best efforts should be devoted for some time to instructing dealers as to the requirements and to getting them interested in us. In due course this letter was submitted by the President to a member of the board of food and drug inspection who was bitterly hostile to Dr. Wiley. Some time later this man took occasion to write to Dr. Wiley that I had, in a letter to the President, accused him of entering into an arrangement with importers by which they were to be permitted for a time to violate the law. But for the wisdom and courage of Dr. Kebler in acquainting me with this action, Dr. Wiley might never have been relieved from the impression of this extreme of treachery.

"In spite of all conflicts within and without the Department, I have now no doubt that the drug trade generally has come to understand that drug inspection, at the port of New York, is conducted legally, justly and impartially, and in a sensible and practical manner."

Dr. Rusby joined the A. Ph. A. in 1889 and after serving in many subordinate offices became its president in 1909.

He resides in the Forest Hill section of Newark, N. J., with his charming family of wife and three daughters.

In closing this sketch we cannot forbear quoting the words of an esteemed contemporary:

"His genius for discovering the motives and his courage in attacking the course of those who are guided by policy rather than principle have made him respected by all who know him and feared by those whose armor is sham and whose weapon is deceit. With all his knowledge Dr. Rusby is not pedantic; and with all his devotion to duty he is not austere; on the contrary, he is as simple mannered, approachable, urbane, frank and friendly a man as one could wish to find for a friend and companion."

## Book Reviews

**THE EXAMINATION OF WATER, FOR SANITARY AND TECHNIC PURPOSES**, by Henry Leffmann, A. M., M. D., Ph. D. Professor of Chemistry in the Women's Medical College of Pennsylvania and in the Wagner Free Institute of Science; President of the Engineers' Club of Philadelphia (1901); Vice-President, Society of British Public Analysts.

Seventh Edition, revised and enlarged with illustrations. P. Blakiston's Son & Co., Philadelphia. Price \$1.25.

This book is one most instructive to all interested in water-supplies, particularly to those having connection with the supply of potable water to cities.

It gives a very interesting short account of the water supplies of the ancient cities of Rome, Athens and Jerusalem, in which is corrected the prevalent error that Roman engineers did not possess knowledge of the fact that water rises to its original level.

After classifying the diverse waters which the sanitary chemist is obliged to handle in his investigations, it treats in detail the analytic operations for the determination of their purity and availability for use and also for their purification.

This, the seventh edition has been extensively revised and the procedures brought into general agreement with those recommended by the American Public Health Association and gives particular attention to processes devised by American Workers in substitution for those of foreign origin.

**THE BOOK OF PRESCRIPTIONS, WITH NOTES ON THE PHARMACOLOGY AND THERAPEUTICS OF THE MORE IMPORTANT DRUGS, WITH INDEX OF DISEASES AND REMEDIES**, by E. W. Lucas, F. I. C., F. C. S., with an introduction by Arthur Latham, M. A., M. D., F. R. C. P.

Tenth edition. P. Blakiston's Son & Co., Philadelphia, Pa. Price \$2.50.

This book aims to supply the defect in present-day medical instruction in its lack of training in prescription-writing and is admirably calculated for its purpose. It informs the medical practitioner of the correct manner of prescribing drugs and gives their proper combinations in order to produce palatable and efficient preparations.

It is a particularly valuable work to be in the hands of every senior student in his work in the hospital, but it is also well devised for the use of every physician who has not received the benefits of a pharmaceutical training and the actual dispensing of drugs.

**THE BOOK OF PHARMACOPOEIAS AND UNOFFICIAL FORMULARIES**, containing the formulas of the British, United States, French, German, and Italian Pharmacopoeias, together with formulas from unofficial sources, as the British Pharmaceutical Codex, the National Formulary of the United States, the Pharmacopoeias of the London Hospitals, etc., the whole comprising about five thousand formulas, by E. W. Lucas, F. I. C., F. C. S., Pharmaceutical Chemist and H. B. Stevens, F. I. C., F. C. S., Pharmaceutical Chemist. P. Blakiston's Son & Co., Philadelphia, Pa. Price, \$3.00.

In this book an effort has been made to group in a simple comparative form the formulas contained in the authorities mentioned in the title and the work will be found most useful for practical pharmacists desirous of securing such information. In addition to this information there are descriptions of the different processes of the exhaustion of drugs, a *Materia Medica* table giving the foreign synonyms for drugs; alcohol and thermometric tables and the relations of metric and imperial measures. The book should be a most useful addition to the library of every pharmacist.

**THE DETECTION OF POISONS AND POWERFUL DRUGS**, by Dr. Wilhelm Autenrieth, Professor of University of Freiburg, i. B., translated from the completely revised fourth German edition by William H. Warren, Ph. D., Professor of Chemistry in Wheaton College. (Illustrated.)

Fourth edition. P. Blakiston's Son & Co., Philadelphia. Price \$2.00.

The introduction of new matter and certain re-arrangements of the text make this, the fourth edition of this work quite a different work than previous editions.

The new matter added is of especial value, treating as it does particularly of special methods of analysis. The work divides the toxic and potent substances into three groups:—those which volatilize without decomposition when treated with steam; those which are non-volatile under the same conditions; and all poisonous metals; and the directions given for the treatment of each of these classes is exhaustive.

In addition to this, Chapter IV treats of poisons not in the three groups enumerated; Chapter V treats of Special Qualitative and Quantitative Methods; Chapter VI,—the Quantitative Estimation of Alkaloids and other principles and Chapter VII treating on Carbon Monoxide Blood, Blood Stains and Human Blood.

Students of Pharmacy will find Chapter VI useful in its treatment of drug assaying.

The translation of this German work into English, Spanish and Italian attests its value.

## Papers Presented to Local Branches

### THE BRITISH PHARMACOPŒIA, 1914.\*

M. I. WILBERT, PH. M.

The appearance of a new edition of the British Pharmacopœia immediately before the publication of the revision of our own Pharmacopœia of the United States lends a peculiar degree of interest to the book and would appear to warrant a study of the characteristic features of this new Pharmacopœia. The history and origin of the British and of the United States Pharmacopœias are also interesting largely because of the fact that our own Pharmacopœia is the direct outgrowth of one of the books that were later combined to form the now official standard for the British Empire.

The British Pharmacopœia in the form in which it now appears, is a comparatively recent publication, the compilation being authorized by the Medical Practice Act of 1858 and its publication directed by the Medical Council Act of 1862 to supersede the previously published pharmacopœias of London, Edinburgh and Dublin, only two of which, the pharmacopœias of London and of Edinburgh had an authoritative legal standing.

The earliest of the British Pharmacopœias was that of the College of Physicians of London, the first edition of which was published in 1618; subsequent editions being printed in 1639, 1650, 1677, 1721, 1746, 1788, 1809, 1815, 1824, and 1836.

The first translation of the London Pharmacopœia by Culpeper was published in 1653, and is particularly interesting because of the liberal abuse of the catalogue of remedies.

The first edition of the Edinburgh Pharmacopœia was published in 1699, and this was followed by new editions in 1722, 1736, 1744, 1756, 1774, 1783, 1792, 1803, 1804, 1806, 1813, 1817, 1839, 1841.

An English translation of the Edinburgh Pharmacopœia was published by Lewis in 1748. This book reappeared in several editions and was followed by translations by Webster, Duncan, Duncan, Jr., and finally James. The translations by Duncan and Duncan, Jr., were widely used in this country and subsequently formed the basis of the American Dispensatory by Cox and of the American New Dispensatory by Thatcher. The Edinburgh Pharmacopœia itself was used as the basis for the Pharmacopœia of the Massachusetts Medical Society, published in 1808, and for the first edition of the Pharmacopœia of the United States, pub-

\* Presented at the meeting of the City of Washington Branch of the American Pharmaceutical Association, January 27, 1914.

lished in 1820. The reason, no doubt, why the Edinburgh Pharmacopœia rather than the London Pharmacopœia was used in this country, is to be found in the fact that during the Colonial period and for years later many American students were sent to study medicine at the University of Edinburgh, which at that time was considered to be the leading medical school in Great Britain, if not in Europe.

The Dublin Pharmacopœia was published as a specimen Pharmacopœia in 1794, and a second edition of this specimen Pharmacopœia appeared in 1805. The first Dublin Pharmacopœia printed for circulation was published in 1807, succeeding editions being published in 1826 and 1850. The latter or third edition was apparently the first of the several British Pharmacopœias to be published in English.

The first edition of the present British Pharmacopœia was published in 1864. At the request of the Pharmacopœia Committee of the Medical Council the Pharmaceutical Society of Great Britain had delegated Mr. Peter Squire to coöperate in the preparation of the British Pharmacopœia and he served as the pharmaceutical editor of this book. As a direct outcome of his work in this connection we have his still popular "Companion to the British Pharmacopœia" which acquired a very wide circulation not only in England but throughout British possessions, and even in the United States, no less than eighteen editions of the book having appeared to date.

The first edition of the British Pharmacopœia was liberally criticized, and the opinions expressed, particularly in pharmaceutical journals, regarding it were not favorable. While it was admitted to have good qualities, serious defects of omission and commission were pointed out and a new edition of the book, edited by Mr. Robert Warington of Apothecaries' Hall, and Professor Theophilus Redwood, representing the Pharmaceutical Society, was published in 1867. An Addendum to this second edition was circulated in 1874, and the third edition of the Pharmacopœia appeared eleven years later in 1885, a further Addendum being published in 1890. The fourth edition of the Pharmacopœia was issued in 1898, and an Indian and Colonial Addendum in 1900. This Addendum, at the request of the Government of India, was published as a Government of India edition in 1901.

The present issue of 1914 is the fifth British Pharmacopœia and, in general appearance, it has much in common with the volume immediately preceding it. It contains a total of 633 pages, sixty-seven more than are contained in the fourth edition, and officializes a total of 816 drugs and preparations as against 826 described in the body of the fourth edition of the same book. The monographs or descriptions and formulas occupy 462 pages, whereas in the issue of 1898 they required only 389 pages.

The additions in the 1914 Pharmacopœia include forty-three, the deletions 168, as against eighty additions and 189 deletions recorded in the Pharmacopœia published in 1898.

The number, nature and kind of additions and deletions represented by a new edition of a pharmacopœia are usually considered to be an indication of the progress or lack of progress reflected by the book as a whole. From this point of view, the present British Pharmacopœia appears to have been rather liberally criticized, not alone in the Medical and Pharmaceutical Journals of different por-

tions of the British Empire, but also in some of the lay Journals, particularly the daily papers of London and some of the larger cities of England. It would be altogether too ambitious a task to discuss the additions and deletions in detail or to reflect even casually the criticisms that have already appeared. For our purpose it will suffice to point out that by far the greater number of the changes were involved by the inclusion in the body of the book of all but forty-five of the titles formerly in the Indian and Colonial Addendum. This rearrangement of the material also accounts for the fact that despite the very great difference in the number of official additions and deletions the number of monographs in the body of the book is only reduced by ten.

Among the additions not as yet included in our own Pharmacopœia of the United States we find:—*Acidum Picricum*, *Adrenalinum*, *Barbitonum*, *Benzaminæ Lactas*, *Cantharidinum*, *Diamorphinæ Hydrochloridum*, *Glucosum*, *Phenolphthaleinum*, *Theobrominæ et Sodii Salicylas*.

Among the titles not recognized in our own Pharmacopœia we find:—*Methylsulphonalum* for *sulphonethylmethanum*, or *trional*, and *Hexamina*, a newly-coined title, in place of our own *Hexamethylenamine*.

Among the deletions we find:—*Cambogia*, *Cantharis*, *Cerii Oxalas*, *Cimicifugæ Rhizoma*, *Cocæ Folia*, *Crocus*, *Elaterinum*, *Ficus*, *Granati Cortex*, *Lupulinum*, *Lupulus*, *Moschus*, *Mylabris*, *Oleum Pimentæ*, *Piper Nigrum*, *Prunum*, *Sarsa Radix*, *Sassafras Radix*, *Sinapis*, *Spiritus Aetheris Compositus*, *Spiritus Vini Gallici*, *Veratrina*, *Zinci Sulphocarbolas*.

Among the deleted galenical preparations there are:—Three Decoctions, eight Infusions, seven Plasters, eight Fluidextracts, seven Extracts, sixteen Concentrated Solutions, six Solutions, two Mixtures, three Pills, sixteen Tinctures, and eight Ointments.

Among the innovations included by the additions and deletions we have the substitution of *Cantharidin* in place of the formerly official *Cantharides* and *Mylabris*. This active principle is directed to be used in the making of *Plaster of Cantharidin*, *Tincture of Cantharidin*, and *Ointment of Cantharidin*, in place of the formerly official corresponding preparations of *Cantharides*.

The deletions noted include *Figs*, *Prunes*, and *Black Pepper*, despite the fact that formulæ for *Confection of Senna* and for *Confection of Pepper* are retained. In these formulæ the corresponding substances are directed to be "of commerce," thus recognizing the principle that the nature and character of widely-used articles is sufficiently well regulated by competition not to require further definition or description.

One of the more evident differences between the fifth edition and the one immediately preceding it is the omission of all reference to the Imperial system of weights and measures in the formulas of the Pharmacopœia, quantities being given in the metric system only, with the exception of the doses where, as a transitional provision the Imperial system has been retained. Despite the fact that the editors of the Pharmacopœia announced that the relation between the Imperial and the metric doses of a given preparation is that of approximate equivalents only, the preference in the statement of round numbers appears to have been shown uni-

formly to the Imperial system rather than to the metric system as illustrated by the following examples:—

		DOSE	
		Metric	Imperial
Aloin .....	2 to 12 centigrams		$\frac{1}{2}$ to 2 grains
Purified Alum.....	3 to 6 decigrams		5 to 10 grains
Amyl Nitrite.....	12 to 30 centimils		2 to 5 minims
Apomorphine Hydro- chloride .....	(By hypodermic injection)		
	3 to 6 milligrams,		1/20 to 1/10 grain;
	(By mouth)		
	6 to 16 milligrams		1/10 to 1/4 grain
Atropine .....	0.3 to 0.6 milligram		1/200 to 1/100 grain
Copaiba .....	2 to 4 mils		$\frac{1}{2}$ to 1 fluid drachm
Cresol .....	2 to 18 centimils		1 to 3 minims
Prepared Chalk.....	1 to 4 grammes		15 to 60 grains

In stating doses for liquid preparations the metric quantities are given in mils, a term recognized by the Board of Trade (May, 1908,) as a short official designation for the millilitre. Americans will be interested to learn that this term was originated by the late Professor Oscar Oldberg in his *Unofficial Pharmacopœia*, published in 1881, and it is a rather handsome compliment to a prominent American pharmacist to have the renewed suggestion to use the word mil in place of the very cumbersome "cc." or cubic centimetre, reintroduced into this country from abroad.

In connection with the doses, the editors of the *British Pharmacopœia* explain that while the doses given in the *Pharmacopœia* are not authoritatively enjoined upon prescribers, it is the duty of the pharmacist or dispenser whenever an unusually large dose is prescribed to satisfy himself that the prescriber's intention has been correctly interpreted. This paragraph would appear to put the onus of dosage on the dispenser and differs from the usage evidenced by continental pharmacopœias which include maximum doses of potent medicines: quantities to which the prescriber is specifically limited and required to note any excess so as to indicate that it is done with full knowledge of facts and not through inadvertence.

The list of articles and preparations the composition of which has been altered, includes fifty-one titles, of which seven preparations were changed to correspond approximately to those recommended in the International Agreement of September, 1906. The strength of forty-one articles and preparations has been altered materially, and of these ten were changed to correspond approximately with the requirements recommended in the International Agreement referred to above. A table is also appended recording the deviations from the recommendations of the International Agreement, the nature of the recommendations and the reason for the deviation.

The list of articles and preparations the names of which have been altered, include a total of thirty-five titles largely of botanical drugs and preparations. No material change has been made in chemical nomenclature and the familiar Latin titles have generally been retained unaltered. The preface also calls attention to

the fact that the English titles are not as a rule literal translations of the Latin titles and that only the more important synonyms have been inserted.

A table of abbreviated Latin names of official drugs and preparations of the British Pharmacopœia is included in an Appendix and has elicited considerable comment, one reviewer expressing the hope that the abbreviations included "will never be put forward as legally binding. They do not appear to be so at present, but the list should not be unnoticed; many of the abbreviations are horrible."

From the preface to the Pharmacopœia it would appear that the same or similar abbreviations are to be included in the Pharmacopœia of the United States, and that the list was included in the British Pharmacopœia in the interest of international uniformity, with the suggestion that they "will probably be found useful to dispensers and others, especially those in foreign countries who have to interpret the abbreviations according to the prescriptions of British practitioners."

The monographs and descriptions of chemical substances are interesting because of the frequent occurrence of a purity rubric and of a modification of that portion of the paragraphs in former issues which purported to be descriptive of the sources or modes of manufacture of official chemical substances. These descriptions have been made more concise, but the physical and chemical characteristics and tests by means of which the substances may be identified and their freedom from impurities determined have been amplified and increased in number.

The quantitative tests for the basic and chemical radicles of ordinary salts instead of being repeated in the text as in the previous edition, or in our own Pharmacopœia of the United States, have been brought together connectedly in an Appendix, the text simply stating the names of the radicles or other combinations which should be present or absent. Infrequently applied tests are as heretofore included in the monographs themselves.

A quantitative limit test for arsenic and a table showing the limits of arsenic in parts per million, also a quantitative limit test for lead with a corresponding table showing the limit of lead in parts per million are given in the Appendices which also include methods for the general determination of acid value, saponification value and iodine value of fixed oils, fats and other products, the determination of esters and of alcohols in volatile oils, the determination of boiling points, melting points, refractive index, optical rotation and specific gravity of official substances, also methods for making extractive preparations, dyes, lozenges, alternative preparations sanctioned for use in tropical countries and a definition of the permissible limit of error in alkaloidal assays.

In connection with the descriptions of botanical drugs the histological characteristics of parts of plants officially recognized are fully described, and in many instances the histological characteristics of the powder are given, particularly when by chemical testing alone the identity or the purity of the article could not be certainly determined.

The number of assay processes for botanical drugs and for galenical preparations and volatile oils has been increased considerably, the present edition requiring the assay of thirteen crude drugs, seven of which are for alkaloids, the assay of twenty-five galenicals and of eleven volatile oils. In many instances the official processes for the assay of drugs and preparations have been revised in accord with

the recommendations of the Reference Committee on Pharmacy of the Pharmaceutical Society.

In connection with the volatile oils and fixed oils, additional tests for identity and purity have been introduced, the characters and tests ordinarily including in addition to requirements for color, odor, and specific gravity, also optical rotation, and, as noted above in many instances, an assay method for the determination of the more important constituents.

Unusual methods of administration have not been specifically recognized and apart from a note by the editors in the preface to the Pharmacopœia that "when official drugs are so directed by the prescriber, the drugs of the Pharmacopœia may be dispensed in non-official forms such as capsules, cachets, granules, compressed discs or tablets, and the like; but the drugs themselves, in all such cases must respond to the official characters and tests."

An index of forty-seven pages makes the book and its contents readily available for reference purposes, and altogether the opinion expressed by the editors of the Pharmacopœia that the Pharmacopœia Committee of the Medical Council, "has now been able to produce a British Pharmacopœia suitable for the whole Empire," appears to be reasonably justified.

---

## MODERN DRUG STORE MERCHANDIZING.

---

E. FULLERTON COOK, P. D.

---

At the January meeting of the Philadelphia Branch of the A. Ph. A., Mr. Louis K. Liggett of Boston, presented an interesting and illuminating analysis of the business side of certain types of modern drug stores.

The following outline briefly reviews his treatment of the subject:

That the proper grasp of the details of business may be insured, it should be divided into departments, each being separately studied and managed and each having separate financial records. Soda water, cigars, candies, prescriptions and general merchandise are classifications which suggest themselves.

The Soda Fountain properly conducted and with careful management should and can be made to yield 50 *per cent.* gross profits. In figuring the costs do not fail to include every expense including breakage, icing, napkins, glasses, etc., etc. Here the quality of the service is of the utmost importance. Selling price is not the main consideration. People are willing to pay more for quality and right treatment.

The basis of a successful soda business is, first, ice-cream which is just right; secondly, cold liquids—10 to 15 degrees above freezing always; with these assured you have the beginning of a good business.

*Cigars:*—The best grade of cigars may be ruined by lack of proper care. An open door to the cigar case and a radiator behind will make "English Cigars" of the finest kind in one week, "water-logged, seasick and dried out." The cigar case should be carefully watched and be gone over at least once every day, to see

that well-filled boxes are always in sight and the proper degree of moisture is maintained.

Buy with much wisdom. Don't load up with dead brands. Here again service counts. One store in Boston, with only a nine-foot case, does over \$100,000 worth of cigar business a year, against keen competition. This is only because they give unusual service. The salesmen in this store know their customers' preferences and serve them with politeness and dispatch. A good cigar business is valuable to a drug store because it brings the men's trade. Give the customer what he wants and give it quickly. Cigar sales should yield, at least, 26 *per cent.* gross profit.

*Candy*:—This is a rapidly growing department in many stores. There are two kinds of candy selling—in packages and in bulk. The first can be bought to yield an assured 32 *per cent.* gross profit. Bulk goods can be bought to yield, theoretically, as much as 40 *per cent.* gross profit, but in practice this always shrinks to 28 or 30 *per cent.* Why? "Because she always gives over-weight (18 ounces to the pound) and each time eats two more."

Don't sell a 60 cent candy for 80 cents. You may sell the first pound but the customer does not return. *Give full value.* Buy to make from 32 to 36 *per cent.* gross profit from candy sales.

*General Merchandise*:—The great problem of every business is to make the store yield a net profit. The proprietary medicine business shows a fluctuating gross profit. Where 92 to 95 cents is obtained for \$1.00 goods it is possible to make from 32 to 33 *per cent.* gross profit. When cut rates prevail the gross profit may be cut to from 12 to 15 *per cent.* or even less with an actual loss on every sale.

The expenses of the retail business in all lines has just doubled in the past twenty years. This is due to the establishment of delivery service, higher-priced clerks, increased lighting requirements, laws cutting hours for labor, etc.

It becomes necessary, therefore, to watch every detail of the business if it is to be made to yield a net profit, and if you cannot do this, get rid of it as soon as possible.

Take at least one accurate inventory. Write up each section on cards or inventory sheets, and then some night call in your friends and call it all off even if it takes all night. Then having figured what your actual gross profits have been, budget each department. For instance, if you do \$100.00 of cigar business a month and you find through careful records and your inventory that you have been making 20 *per cent.* gross profit, limit your purchase to exactly \$80.00. If you can do the same business (\$100.00 worth) that month, you can be sure of the 20 *per cent.* gross profit. On the other hand, if stock becomes short you will know that something is wrong and will be interested enough to investigate.

Start with one department, study it in this way and budget it, as suggested, and you will soon be so interested and so greatly benefited, that you will find it possible to treat all departments in the same way.

Every business should be analyzed and studied, and made to conform as nearly as possible to carefully outlined plans, which insure a profit. The following illustration serves as a model, and although subject to slight variations, depending

upon the nature of the business, it yet affords a basis for comparison which should be helpful to every man engaged in the drug business:

Assuming that the sales are \$3000.00 a month, and stating all *per cents* as *per cent.* of the total sales, then:

Total sales .....	\$3000.00	100	per cent.
First cost of goods .....	2000.00	66 $\frac{2}{3}$	per cent.
<hr/>		<hr/>	
Gross profit .....	\$1000.00	33 $\frac{1}{3}$	per cent.

From this \$1000.00 must now be paid all expenses, and from it must also come the net profit, if any is to be made. It should be divided about as follows:

Rent, heat and light .....	\$ 210.00	7	per cent.
(the only fixed charges)			
*Clerk hire .....	360.00	12	per cent.
Advertising .....	60.00	2	per cent.
All other expenses .....	120.00	4	per cent.
Net profit .....	250.00	8 $\frac{1}{3}$	per cent.
<hr/>		<hr/>	
	\$1000.00	33 $\frac{1}{3}$	per cent.

For a business of this size, budget yourself to buy only \$2000.00 of goods a month and you will have \$1000.00 in bank for expenses and profit. You should spend 2 *per cent.* of your sales for advertising if you would retain your business and slightly increase it, but be sure the advertising is judiciously done and in such a way that it pays.

Always put your detailed expenses down in black and white and study it. Freight on goods should go to expense and should not be added to cost of goods. You will then soon eliminate it by buying the same goods in some other way without freight cost, or else make the other fellow pay the freight. If your electric light exceeds your limit set for that expense, you will immediately want to know the reason why, and so each expense item will come up for study and analysis. Remember your net profit depends upon keeping expenses down.

To conduct a business of this amount how much capital is necessary? The location makes a great difference, and the kind of goods sold is also an influence. You should aim to make at least four turn-overs of stock every year. Don't allow general merchandise to remain on the shelf; if anything, not a staple, proves to be a slow seller, get rid of it through a special sale. By turning stock at least four times on the average each year, a \$3000.00 a month business would require a capital of about \$6000.00 for fixtures and \$8000.00 for stock; a total of \$14,000.00. If the turn-overs can be made more frequently less capital is necessary; if less frequently, a larger capital will be required.

---

\*If a large part of the business is in the prescription department, the per cent. of expense for clerk hire will increase, but the first cost of goods will proportionally decrease.

## THE SALE OF POISONS.\*

WM. MITTELBACH, PH. G.

The sale of any poisonous substance is always connected with more or less responsibility by those engaged in its distribution; and the legal restrictions placed about such sales are fairly well designated in our state law. Our law in this state (Missouri) is about as clear and complete as in most other states; and the list of poisons recognized under schedules A. and B. as extensive as in other states. Massachusetts' law sets out the most complete and extensive list and is a drift in the right direction. This, in my opinion, is a better law, and throws more safeguards about the sale of poisons. I hold that all substances that are of a dangerous or poisonous nature should be registered—their distribution or sale, I mean. As the Missouri law now stands, only a few of the most potent or powerful drugs or chemicals must be registered; while a long list of less potent, yet of dangerous character, can be distributed or sold almost *ad libitum*—the only requirement being that the purchaser be informed of their dangerous or poisonous character.

We all recognize that all drugs are more or less potent—otherwise they would have but little therapeutical value. Then why draw a line anywhere in controlling their sale to the laity? I, therefore, hold that no distinction should be made in listing substances sold by the pharmacist as "poisons" or "poisonous substances"; but that the sale of all should be placed upon the poison register. The argument that poisons should only be distributed through the physicians, and upon their written order, is rather weak and impracticable. The licensed pharmacist is better qualified to guard the sale of poisons than is the average physician. He, being directly responsible for the distribution of poisons, will naturally watch more carefully their sale.

The registration of all poisonous substances involves very little additional trouble and will simplify the whole matter. As new drugs, chemicals or substances are brought into use, they, if of a dangerous or poisonous character, can be added to the list. Such a change in our law will be beneficial, and simplify the sale of poisons while it will add to the pharmacist's protection.

## COMMERCIAL PHARMACY—A TIMELY TOPIC.\*

ALFRED W. PAULEY.

We are living in a day and age when we are obliged to recognize commercial pharmacy as a very important factor. First of all, let us consider the definition of commercial pharmacy. One of the best definitions that I can mention is this:—Commercial Pharmacy is a science that treats of mercantile transactions pertaining to pharmacy, or it may be defined as the business-end of pharmacy.

If it is true that commercial pharmacy represents the business-end of pharmacy,

---

\* Read before St. Louis Branch, January, 1915.

then we must recognize it and admit it into our professional ranks, in the colleges as well as the drug stores. It was my pleasure, not so very long ago, to listen to several very prominent addresses made before a body of men and women who were gathered in St. Louis for the purpose of promoting social, professional, educational and business interests. These men represented many states of our great country, and are noted the world over for their professional, chemical and pharmaceutical knowledge. One of the speakers in his address made a comparison of pharmaceutical classifications, which was divided into two classes; one whom he said studied pharmacy with a view of making it a profession, while others studied with a view of making it a vocation. He seemed to lay special stress on the professional student overlooking the importance of commercialism, which to my mind is absolutely essential in pharmacy to-day. In order to make a pharmacy successful professionally, we must use commercial methods. Now let us consider one of the causes for adopting commercial pharmacy. Can any one of us run a drug-store to-day as our forefathers did? We may but look back, to the days in which the professional pharmacists ruled and governed pharmacy, and before the time of the existence of the department-stores and commercial drug-stores; and we must give those men credit for running apothecary shops in an ideal manner; but isn't it likewise true that all progressive professional and commercial enterprises have applied themselves to the modern-day methods due to the vast changes that were forced upon them? Let us consider some of the reasons that caused us to take up the commercial end of pharmacy. We may, individually, remember that a diphtheria case in the neighborhood of our drug-store would result in considerable prescription work for the patient, and, usually, the patient required medicine daily for two, three or possibly four weeks. To-day one injection of diphtheria anti-toxin is sufficient in most cases. Thus the prescription trade is not obtained. Besides this, we have a number of other diseases which now are treated by the use of Vaccines, Bacterines, Phylacogens, Salvarsan and the like. Furthermore, we, to-day, have Christian Science, faith healing, the Fletcher System, Physical Culture, Psychology and many other things of similar nature that deprive the pharmacists of the prescription business that he formerly enjoyed. With this condition apparent, isn't it true that the commercial departments in the drug-store of to-day help reduce the prices that we would be obliged to charge for prescriptions had these commercial departments not been established, or in other words, the commercial departments have a tendency to cut down your overhead expense. Furthermore, let us consider with all due reverence to the professional man of former days, and ask this question:—Has he achieved success financially?—Has he reached his ideals? If he has professionally we must honor him. We, however, must have more than this professional ideal in mind, especially if we have families to support, or other obligations to meet, and therefore in order to make a financial success "which in my mind is absolutely essential," we must combine commercial pharmacy with professional pharmacy and get the professional educators willing to coöperate with us. Then combine their ideals and we will have commercial professionalism or professional commercialism as the one ideal for which to strive. There is a difference between commercial pharmacy and commercialized pharmacy. Commercial pharmacy, as its name implies, is the trading of commercial products for the benefit of the public

as well as for profit; while commercialized pharmacy, in my mind, would represent trading for the profit and disregarding the public. Commercial pharmacy has been scorned by a great many professional pharmacists, but I want to tell you that the commercial pharmacist is just as honorable and upright in his dealings as the professional pharmacist, and if this is true, then let us get together and make commercial pharmacy one of the important factors of the twentieth century, or sooner or later, we will have the universities encroaching upon the rights of the regularly instituted colleges of pharmacy and take from them that which they have worked so hard to build up.

Let us consider the words of Cicero, who so wisely said:—"It is not the place that maketh the person, but it is the person that maketh the place honorable." Therefore, let us follow the footsteps of Atkinson who directs us as follows:—"Put in your own mind the existing condition which you wish to become real; then see the thing as you wish it to be"; and as Alex. Bell likewise gives us this valued advice in saying "Concentrate all your thoughts on the work in hand. The sun's rays do not burn until brought to a focus." Just so, the sun's rays of commercial pharmacy will likewise not burn until brought to a focus. Feeling satisfied that most of us are in accord with these commercial pharmacy ideas, let us proceed to take up the most important steps that are necessary in making commercial pharmacy a success. Most essential is that of salesmanship. Salesmanship is the scientific cultivation of good will. Another definition is that salesmanship is honesty, courtesy, tact bound up with an interest in, and a thorough knowledge of your stock, all resolving into the art of converting a transient patron into a steady customer. All of us, possibly, have seen the illustration of salesmanship conveyed by a prosperous business man to his son as he started out in life, which bears this inscription:—"Remember, Jakey, when you sell a customer what he wants, that is nothing; but when you sell him what he don't want, that's business." Some of the most essential factors in salesmanship are first:—A salesman must have a thorough knowledge of his merchandise and not attempt to sell winter merchandise in the summer, or attempt to sell ice skates for sake of example, in the Fiji Islands.

So that the most important thing is a thorough knowledge of the goods you have for sale. He should know of what it is made, how it is made, what it is for and all that. It will go to show the customer that you are perfectly familiar with the merchandise you have to sell. A good salesman must possess, besides this knowledge of his merchandise, all the attributes of a salesman. These three particular factors are essential:—

#### PUSH, POWER AND PERSONALITY.

Under the head of Push comes initiative, ambition, enthusiasm and tact. He must have power to convince. The fact is, that a salesman must possess the power to make a customer feel as he does about the product he has to sell, and *this is one-half* of the battle. His personality goes a long way in making the people feel they are welcome in his store. As I once heard a customer say, "I like to go into a warm store; not a steam-heated store, particularly, but a heart-heated store. The store where the clerks act as though they were glad to see you. I like to go into a store where I feel welcome. I like to go into a store where there is no unnecessary delay when I ask for an article. I like to go into a store that is cleanly,

and these points show personality." Then he must be optimistic. The next essential that I would consider would be that of:—

#### HEALTH, HAPPINESS AND HARMONY.

Health, as you know, is the greatest factor in keeping business going right. Happiness is a factor that keeps your organization in good running order like good oil used on machinery will keep it running right. The employee with a grouch can spread more dissatisfaction than the boy with the measles can spread the infection in a crowded room. Harmony is absolutely essential because no store, no home or factory can really prosper unless the employees work in harmony, and the proprietor should likewise work in harmony with the help. Who should the salesman work for, and who is the boss of the store? It is the customer that you and I are working for. It is the customer that you and I are here to please. It is the customer who pays your wages and mine. If it were not for the customer, you and I would be looking for a job and we might not get one as good as the one we have. Now, if you are sitting behind your counter doing nothing, and you see a customer (the boss) coming,—Jump.

The commercial pharmacist in his commercial field has a decided advantage. A well-known physician once expressed himself thus:—"A physician renders his service to the sick, the poor and the ignorant, while the pharmacist renders his service to the well, the wealthy and the wise." He infers that we are better off and can keep in better spirits when trading with that class of people. While I am not in accord with all his statement, yet I feel, to a degree, that pharmacy has its advantages. This being the case, let us be optimistic. Let us put on the smile of the optimist and discard the smile of the pessimist. Go forward to make every day count and if possible make some of them count for two, and let us not put anything in the way of the advancement of commercial pharmacy as we do not know how far-reaching it may be. Be kind to your fellow neighbor; do good whenever you can.

Remember the words of A. B. Hagemann which reads as follows:—"I shall pass through this world but once. Any good, therefore, that I can do or any kindness that I can show any human being, let me do it now. Let me not defer or neglect it, for I shall not pass this way again."

---

### THE CULTIVATION OF MEDICINAL PLANTS IN THE UNITED STATES.\*

---

F. A. MILLER.

---

The cultivation of medicinal plants in the United States is only in the very earliest experimental stage. Whatever may have been done toward investigating the peculiarities of growth of this class of plants, has so far had little influence upon their commercial production. With the beginning of the work of the United States Department of Agriculture on the cultivation of these plants and the interest shown by colleges, scientific societies and commercial institutions,

---

\* Abstract of an illustrated lecture delivered before the Chicago Branch, November 17, 1914.

our knowledge of the behavior of a number of the more important ones has gradually increased until we feel more confident of success. To the many inquiries upon the possibilities of success, however, we must still reply in a cautious and conservative manner. This attitude is advisable and indeed necessary for several reasons. To enumerate, a druggist, doctor, farmer or other individual wishes to engage in the commercial cultivation of medicinal plants. Their questions usually come in the following order:—what to grow, what species used, where to obtain authentic, viable seeds, how and when to plant, on what type of soil, when and how to harvest, what part or parts of plant used, how cured and packed, principal markets, prices paid, and annual consumption? Apply this series of questions to any one of the more valuable drug plants such as digitalis, belladonna, henbane or cannabis, and who among us cares to undertake the task of answering them? It is true that these are the very questions that are under investigation, but as yet only a beginning has been made toward their solution. Taking up these problems in their logical order, we find that they fall into certain classes.

The first of these classes includes all the problems of propagation. This involves the sources of seed and plant supplies and the accuracy of names, methods of seeding, as to whether or not open-field sowing can be practiced or the necessity of greenhouse accommodations in carrying the plants through the earlier stages of development. Vegetative methods so commonly employed by gardeners and florists are little used with medicinal plants. It is one form of this method that has proven so successful in the propagation and re-setting of peppermint and spearmint. The second class of problems to be solved is that pertaining to the manner of cultivation. This includes duration of growth requisite for a harvest, whether annual, biennial or perennial; nature of tillage, as to the use of hand or power labor; types of soils and fertilizers and their influence, both upon the production of crude material and the relative percentage of active principle. Following the natural order of procedure, class three covers the operations of harvesting. The nature of these operations varies widely according to the character of the part of the plant used. Roots, seeds, leaves and flowers involve as many operations and, what is of considerable importance, usually require special types of machinery or much expensive hand labor not common in regular agricultural practice. Concerning the time of harvesting these various parts, little is known of the seasonal variations of the active principles. The process of curing represents the fourth class of operations to be considered. It is self-evident that medicinal plant products cannot be cured in the same manner or by the same methods as agricultural crops. A crop of digitalis, or stramonium, cannot be harvested and cured with the same ease and rapidity as a crop of corn, oats or wheat. Handled in large quantities, these drug crops would all require a special equipment in the form of drying sheds, cutting machines, etc. At this point the time of harvesting is in question. When should the various classes of drugs be gathered in order to show the greatest medicinal value? We are all familiar with the wide variations exhibited by plant products as the plant progresses from the earliest stages of growth to maturity, and whether it is an alkaloid, a glucoside, a resin or what not, there is some stage in the life history of the plant when these products are present in greatest quantity. While this

has been determined to some extent for a few forms such as belladonna, stramonium and bloodroot, there is still much to be done before we can say just when a plant or plant part should be collected, in order to give the best product in proportion to the highest yield of crude material.

Thus it is evident that the whole problem of drug cultivation is still one of experimentation. That it will pass this stage successfully, especially with reference to the most essential vegetable drugs, we have little doubt. This success, however, will probably not fall to the lot of the farmer or layman. Little assistance can be expected from those people in solving the many-unsettled problems. As with the average drug collector, they see little necessity in the careful preparation of materials going to make up pharmaceutical preparations. On the other hand, it is their opinion, as well as that of many others, that medicinal plants will grow and thrive without any care or attention. In this respect, I know of nothing better to say to the beginner in drug-growing, than that medicinal plants do not grow and flourish, out of an impossibility to do otherwise, but that they have an excuse for living and growing, in that they respond to the same selective agencies as other economic forms and exhibit during their life history, a delicacy of balance, with reference to their active constituents, so essential that an error of a few days in harvesting and curing may turn success into failure. The mere fact that a form grows commonly about the fields, or appears as a troublesome weed in and about farm lots, or may be grown with comparative ease as a decorative or garden form, does not necessarily indicate that it will behave in a similar manner under field conditions. Indeed, this is rarely the case, and close observations will reveal the fact that most of our native wild forms are growing under an environment not at all comparable to field conditions as interpreted in terms of agricultural science. Too many recommendations based solely upon back-yard observations, have already been made for growing certain medicinal plants. Also, a too liberal spirit has been shown by some in the selection of forms best adapted for cultivation in this country. In my mind this number should be comparatively small and, even under the present market conditions, should not include more than twenty-five drugs, some of which are, aconite, belladonna, burdock, calendula, chamomile (German and Roman), cannabis, colchicum, conium, convallaria, digitalis, goat's-rue, hydrastis, henbane, larkspur, marshmallow, pulsatilla, rue, savin, stavesacre, stramonium, and wormwood. A clear understanding of these forms as to species used, methods of propagation, systems of seeding, cultivating, harvesting, curing and packing, should be had before attempting to make recommendations for their commercial production.

Taking up the question of drug-growing from another viewpoint, let us consider the possibilities of improvement from the stand-point of plant-breeding. We should not be satisfied with merely growing and domesticating these wild medicinal plants, but should so improve them through selection, hybridization and the testing of different species, varieties and strains, that better and more uniform crude products can be obtained. In attempting to thus improve medicinal plants, we are not attempting a new problem. We are only applying old and well-tried principles to new forms. Who of you, would at this day and age, turn to the woods and fields for plants of the strawberry, raspberry, blackberry, plum or a host of others, with which to re-stock your gardens and orchards? The idea of

wild, native ancestors for all economic plants in existence, rarely occurs to the layman and if so, it is quickly dispelled by the ever-ready nurseryman to supply him with new and improved varieties especially adapted to certain soil and climatic conditions. These varied forms have added much to our daily health and pleasure. Our eyes are delighted with the beauty of form and color of some favorite fruit, and our appetite appeased by a flavor so fitting to our individual tastes as not to be possessed by any other variety in existence. And so, in health, we enjoy the products of the plant-breeder, while, in sickness, we are subject to all the variations and imperfections of nature, in the use of products obtained from plants of unknown parentage and growing under conditions so adverse that their life history is one continued struggle for existence. Why not treat disease, in so far as botanical drugs are involved, with preparations derived from carefully selected, and improved strains, grown under controlled conditions and in such a manner that greater uniformity and high quality would be insured? We should have a strain of belladonna testing six- or seven-tenths of one *per cent.* of alkaloids instead of three-tenths, a strain of henbane which could be collected and cured in such a manner that barn-yard refuse could be eliminated, and assaying one-tenth of one *per cent.* instead of the now almost impossible seventy-five thousandths of one *per cent.* With stramonium a strain has been developed, which last year tested seventy-four hundredths, as compared with wild plants of the same locality which tested thirty-four hundredths. *Digitalis lanata* has shown in preliminary tests, an activity much greater than the official species. True, this activity may not be due to the same active constituent, or combination of constituents, as that of the species *purpurea*, but the fact that there does exist a more toxic species than the one in common use, indicates the necessity for investigation and the possibility for the plant-breeder to develop an improved strain. And so we might continue to take up the various phases of the problem, as to the possibilities of developing annual strains of such forms of biennials as digitalis, henbane, conium, etc., and the influence this would have upon the success of commercial production. In this respect the standards of the pharmacopœia must be reckoned with. These standards must be the guide of the prospective drug-grower, for, in many instances, they, in themselves, point out the many difficulties to be overcome if the proposition is to be a profitable one. For instance, the present pharmacopœial requirement for digitalis, includes only the leaves from flowering plants. This plant is almost strictly a biennial, meaning that land must be occupied two successive years by the plant before a harvest is realized. It is also a plant that cannot be seeded by open-field methods, but must be started in the green-house and transplanted. The question immediately arises as to the advisability of recommending this plant for cultivation. With belladonna and stramonium, only leaves are official, while it has been found that the stems of both of these plants contain at certain stages appreciable quantities of alkaloids. If the whole above-ground portion of these plants could be used, it would greatly facilitate the operations of harvesting and curing and at the same time materially increase the yield of crude material. Also, only the species *Datura stramonium* is now official, while it is known that the species *Datura tatula*, which is more common in this locality, contains as much and in some instances even more alkaloids. While some may claim that the alkaloids of these two plants are not identical, still

their close botanical relationship and the fact that we have evidence that European stramonium leaves are many times probably a mixture of these two forms, strengthens the assertion that there is little difference in their therapeutic value.

And so we might continue to take up the various problems of drug cultivation, together with their probable solutions, but space will not permit. In conclusion, therefore, it should be clearly understood that these problems are not simple ones and those undertaking their solution should bear in mind that the cultivation of medicinal plants involves more than merely allowing crops of weeds to grow in spite of themselves, in cutting them down when most convenient, pulling them out by the roots or otherwise, and quickly transferring them to the manufacturer who will be waiting with open hands to receive them at fancy prices. It has seemed advisable, therefore, to recommend to those interested in drug-growing, that they begin on a small scale with a few of the most promising forms, and that they be so situated and equipped that they can carry these through an experimental stage, developing their method of propagation, seeding, harvesting, curing, etc., before attempting any operations upon a commercial scale.

BOTANICAL DEPARTMENT, ELI LILLY & COMPANY, INDIANAPOLIS, IND.

## CAN THE PHARMACOPŒIA AND THE NATIONAL FORMULARY BE MADE POPULAR WITH PHYSICIANS?

---

BERNARD FANTUS, M. D.

Professor of Pharmacology and Therapeutics, College of Medicine of the  
University of Illinois.

---

Time and again has the idea been expressed that physicians as a class do not take enough interest in the Pharmacopœia and the National Formulary. As the truth of this proposition is quite generally admitted, it is probably unnecessary to adduce proofs in support of the assertion. All will agree that it is desirable to make these formularies popular with physicians. The question is: Can it be done?

In an article entitled: "Why physicians do not read the Pharmacopœia," Dr. Chambers (1) summarizes the reasons as follows: First, the physician fully trusts the application of its information to the pharmacist without question; and, secondly, the information the physician seeks for practical application by himself is not contained in the book. So little, indeed, of practical value to the physician is to be found in the book, that we might fairly raise the question: Why *should* physicians read the Pharmacopœia? An additional reason for the indifference of the physician toward the Pharmacopœia is the impression forced upon him that the Pharmacopœia is non-progressive; for nearly every mail brings to the doctor cleverly worded advertisements for proprietary medicines, all of which, no matter how varied their nature, agree in one respect, namely in claiming directly or indirectly, that they represent a decided advance or innovation in respect to the Pharmacopœia.

Now what can be done to make the Pharmacopœia more popular with those for whose guidance chiefly the work is published? Should we attempt this by intro-

ducing information on pharmacodynamics and on therapeutics? Assuredly not, for the Pharmacopœia is a book of standards. Or should we introduce into it the latest and the untried; sacrificing its dignified conservatism? Of course not. Though it is a fact that the Pharmacopœia contains only well established and much used drugs and preparations, it is unfortunately also true that doctors do not look upon this book as a guide for the determination of the value of medicaments. It is well known that the Pharmacopœia contains articles of admittedly doubtful utility; and also that, for various reasons, it cannot contain all the medicaments of value. To limit the Pharmacopœia to drugs of undoubted therapeutic value, has been strenuously advocated of late; and, as a principle, the idea appears perfectly sound. Its application would, however, eliminate from the book many drugs that are much used, thereby lessening the value of the Pharmacopœia to the pharmacist; it would offend many of the rank and file of the medical profession, wedded as some of them are to the use of some of these drugs of doubted activity; it would probably not enhance the popularity of the Pharmacopœia, at least not for quite a time to come.

Hence it may seem an almost hopeless task to make the Pharmacopœia popular with physicians. This statement is made without questioning, in the least, the utility, aye the necessity of the Pharmacopœia; that is admitted by all physicians. The Pharmacopœia is as necessary as is our code of laws. Yet our legal statutes do not constitute popular reading, even though they are made for the people.

Nevertheless, it seems, that everything possible ought to be done to acquaint physicians with the forthcoming revision of our formularies. Perhaps one way in which this society might be of help in this direction would be by the publication of a "Commentary upon the U. S. P. and N. F. for Physicians," a booklet that would briefly set forth the facts connected with the new formularies that are of interest and importance to physicians. Of course, nearly all medical publications will give lists of the changes, the additions and the deletions that have occurred; so that a mere dry statement of the facts would not be called for. The book issued by this society might go further. It might state the reasons for the changes, so that physicians might understand why they are asked to inconvenience themselves by departing from accustomed ways of prescribing. Such commentary might perhaps also give brief historical notes in connection with important drugs and preparations; for historical knowledge is eminently calculated to inspire respect or at least an understanding for things as they exist at present. Posology, the study of doses, is a very vital matter for medical men; and the maximum doses of various pharmacopœias, minimum fatal doses wherever available, and possibly children's dosage as given by various authorities might profitably be included in such a book. A brief statement of legal enactments in connection with drugs might also be of interest. There are, no doubt, many other items of information, as, e. g., the form in which various medicaments are best and most commonly prescribed, that might be included, so as to make the book truly worth while for the physician. On the other hand, pharmacists should not presume to offer to the physician information on pharmacodynamics or on therapeutics, as these subjects are decidedly out of the sphere of the pharmacist's study.

That something can be done to popularize the preparations of the U. S. P. and N. F. has been shown by a statistical investigation carried on by the author sev-

eral months ago, by means of a *questionnaire* sent to some of the leading pharmacists of this country. An analysis of 10,000 prescriptions (2) showed that 24% of them contained proprietary medicines, which, though still too high a figure, shows a decided improvement over the figure obtained by Motter (3) in 1906, who as the result of an examination of 5000 prescriptions found 47% calling for proprietaries. This reduction in the use of proprietary medicines by about one-half may, it seems, be justly ascribed to the propaganda in this behalf carried on by the American Medical Association, through its Council on Pharmacy and Chemistry, and by the National Association of Retail Druggists. These figures mean that the preparations of the Pharmacopœia can be made more popular by propaganda. The forthcoming revision of the Pharmacopœia and the National Formulary offers an excellent opportunity for renewing them. Might not this society do its share in advancing the good cause?

## ESTIMATION OF CINEOL IN OIL OF EUCALYPTUS.\*

JOSEPH L. TURNER AND RALPH C. HOLMES.

The question of an accurate determination of the quantity of Cineol in Oil of Eucalyptus is still unsettled, notwithstanding the quite considerable amount of research which has been devoted to it, and, judging from its present status, it will not be settled for some time to come. This is to be regretted the more, since it is now established beyond dispute that the value and therapeutic action of eucalyptus oils depend exclusively upon their content of cineol (eucalyptol). Various methods proposed heretofore, without exception, suffer from one shortcoming—gross inaccuracy; either due to the wrong basis of method, or to the instability of those compounds which have been suggested as serviceable for the separation of Cineol.

To the class of methods based on wrong premises belong the "Permanganate Method" proposed by Francis D. Dodge (Journal Industrial and Engineering Chemistry, Vol. IV, August, 1912, p. 529), and the "Resorcinol Method" proposed by Schimmel & Co., (Semi-Annual Report of Schimmel & Co., October, 1907); the latter method is now slated for inclusion in the Ninth Revision of the United States Pharmacopœia, and it will thus become responsible for the admission into the pharmaceutical practice of inferior eucalyptus oils, as we propose to show further below.

The methods based on the separation of unstable addition products of cineol, are:—the Phosphoric Acid method and the Hydrobromic Acid method.

The various methods mentioned will be outlined briefly, as it is not our purpose here to enter into a thorough discussion of these. Exhaustive information, both

\* Presented at the November meeting of the New York Branch of the American Pharmaceutical Association, November 9, 1914.

*pro* and *con*, may be obtained from the literature on the subject, and especially by perusing the Semi-Annual Reports of Schimmel & Co.

1. *Phosphoric Acid Method*:—"Introduce into a beaker a solution prepared by dissolving 10 cc. of Oil of Eucalyptus in 50 cc. of purified petroleum benzin; immerse the beaker in a freezing mixture and add phosphoric acid, drop by drop, with constant stirring, until the white magma of cineol phosphate formed, begins to assume a yellowish or pinkish tint; then transfer the magma to a force filter, wash it with cold purified petroleum benzin, and then dry it by pressure between two porous plates. Transfer the precipitate (cineol phosphate) to a narrow graduated cylinder, and add warm water, which will cause separation of the cineol. The volume, in cubic centimeters, of the separated oil, multiplied by 10, represents the volume *per cent.* of cineol (eucalyptol)."

The addition product of eucalyptol with phosphoric acid, as obtained by this method, is a semi-solid sticky substance which decomposes very readily and renders a quantitative separation very difficult, if not altogether impossible. In consequence of this, the results obtained by this method are invariably too low.

2. *The Hydrobromic Acid Method* is carried out as follows:—"In a highly cooled solution (freezing mixture) of 10 cc. eucalyptus oil in 40 cc. low-boiling petroleum ether, (b. p. about 40°), *absolutely dry* gaseous hydrobromic acid is introduced until a precipitate is no longer formed. The pure white hydrobromide of cineol formed is rapidly collected with a suction pump, and washed with cold petroleum ether. Into the filtered-off liquid, hydrobromic acid is again introduced, any precipitate formed is collected separately, and then added to the bulk. For the purpose of removing the petroleum ether, the cineol hydrobromide is left standing for a quarter of an hour in a vacuum; it is then rinsed with a little alcohol into a cassia flask, and decomposed with water. The cineol separated off is brought into the neck of the flask by the addition of more water, and the quantity of the oil read off the scale. By multiplying with 10, the cineol content of the oil employed is obtained in *per cent.* by volume."

This method has the same drawback as the Phosphoric Acid method, namely, rapid decomposition of the addition product. Moreover, the procedure for obtaining the cineol hydrobromide is a very complicated one, and is not suitable, therefore, for ordinary practical purposes.

3. *The Potassium Permanganate Method* is based upon the fact, that, in the cold, cineol remains practically unattacked by potassium permanganate, whereas, the remaining constituents of the oils in question (eucalyptus oil and cajuput oil) are oxidized into soluble compounds. The process is carried out as follows:—"10 cc. of the oil under examination are placed in a narrow-necked flask, cooled with ice-water and shaken with a gradually added 5 to 6 *p. c.* solution of potassium permanganate, until the latter is present in excess. The mixture is then left standing in ice-water for from 12 to 18 hours with occasional shaking, after which the manganese peroxide which has separated out is brought to solution by means of a careful addition of sulphurous acid (or sodium bisulphite + hydrochloric acid). The unattacked oil (eucalyptol) is brought into the neck of the flask, pipetted into a graduated tube, washed with a little alkali, and estimated volumetrically. Its sp. gr. should be 0.920 to 0.930 (15°); it should be inactive, and dissolve in 3.5 vols. 60 *p. c.* alcohol at 25°."

We have not investigated this method personally, but are rather willing to ac-

cept the criticism as published in Schimmel & Co.'s Semi-Annual Reports, for April, 1913, p. 62, containing results of experiments on known mixtures of cineol with pinene and terpineol. For instance, a mixture containing 25% cineol and 75% pinene, when estimated by this method, showed a cineol content of 95%; a mixture of 50% cineol and 50% terpineol, on the other hand, yielded only 30% cineol. Time does not permit us to enter into a more complete discussion of these results.

4. *Resorcinol Method*, or more correct, *Resorcinol Methods*, since there is an "original" method as described in Schimmel & Co.'s Reports for October, 1907, in Gildemeister & Hoffmann's "Volatile Oils," 1913, p. 601, and as proposed for the inclusion in the Ninth Revision of the U. S. Pharmacopœia, and also a "Modified Resorcinol Method" as given in Schimmel & Co.'s Reports for April, 1908.

The "original" method is based on the fact that cineol forms an addition product with resorcinol, which is soluble in an excess of concentrated resorcinol solution.

The process is carried out as follows:—

"To 10 cc. of oil contained in a 100 cc. cassia flask enough 50 p. c. resorcinol solution is added to fill the flask about four-fifths. For five minutes the mixture is thoroughly shaken, and then that portion of the oil which has not gone into solution is driven into the neck with resorcinol solution. Any oily particles adhering to the walls of the flask are caused to rise to the surface by rotating the flask or gently tapping it. After the resorcinol solution has become perfectly clear, which usually requires several hours, the volume of oil remaining is read off, the cineol content ascertained by subtracting this amount from 10 and the resultant multiplied with 10 in order to obtain the percentage by volume. Oils very rich in cineol are advantageously diluted with an equal volume of turpentine oil since the cineol-resorcinol occasionally crystallizes from concentrated solutions thus rendering futile the entire process."

It soon became apparent, however, that this method gave too high results, for the reason that constituents of eucalyptus, other than cineol, are also soluble in the resorcinol solution, and further investigation of the subject, led to the "Modified Resorcinol Method," which consists in distilling the oil of eucalyptus at such a rate that only one drop distills over in one second, collecting the portion distilling between 170° and 190° C., and subjecting this portion to the estimation by the above described Resorcinol Method.

We have examined a number of oils, both by the "original" and "modified" Resorcinol Methods, and have reserved our criticism of these for the latter part of our paper.

Many a chemist's patience has been sorely tried by the Phosphoric Acid method of separating cineol, as outlined in the U. S. P. VIII; and, therefore, the Resorcinol Method, as proposed originally by Schimmel & Co., and as described in the last edition of Gildemeister & Hoffman's "Volatile Oils," seemed to afford an easy and accurate means of estimating cineol. However, it became evident at the first application of this method, that the new process was not above suspicion, especially when some eucalyptus oils, persistently refusing to form a semi-solid precipitate with phosphoric acid, showed unusually high cineol content when assayed by the Resorcinol Method.

The logical idea then suggested itself of trying arsenic acid instead of phos-

phoric acid, with a view of obtaining a more stable addition product, and the results so obtained exceeded our expectations. Later, a search through the literature revealed the fact that the idea was not original with us, since cineol arsenate became the subject of a patent as early as June 20, 1901 (German Patent No. 132606, U. S. Patent No. 705545), and according to Thoms & Molle (Arch. der Pharmazie, 242 (1904), p. 172), they used arsenic acid in February, 1901, for the purification of cineol as well as for its separation from various fractions of the Oil of Bay Laurel. Nevertheless, we justly claim the credit for being the first to apply arsenic acid to the *quantitative estimation* of cineol.

We found that by adding approximately an equal volume of an 85% solution of arsenic acid to cineol, a white, solid, crystalline substance resulted, which is sufficiently stable to permit handling it in the air, and which is decomposed by hot water into its components, that is, cineol and arsenic acid. A compound obtained by mixing equimolecular quantities of cineol (152.98) and Arsenic Acid (140.9) was tested for its stability when exposed to air at ordinary room temperature with the following result:—

5 hours in open air	Temp. 25° C.—Loss: 2.9%
22 hours in open air	Temp. 25° C.—Loss: 6.0%
29 hours in open air	Temp. 25° C.—Loss: 7.0%
45 hours in open air	Temp. 25° C.—Loss: 8.4%
69 hours in open air	Temp. 25° C.—Loss: 9.6%

The determination of cineol in cineol-bearing oils by means of arsenic acid is carried out as follows:—

Deliver from a pipette 10 cc. of the oil into a glass dish (preferably a round bottom one) of 50 cc. capacity, which is imbedded in finely cracked ice. Add 10 cc. of concentrated arsenic acid (containing about 85% arsenic acid; (see "Note" below) and stir until precipitation is complete. When the mixture ceases to congeal further, allow to stand ten minutes in the ice. *At this point*, if the mixture forms a hard mass, indicating an oil rich in cineol, 5 cc. of purified petroleum ether should be added, and the mass mixed well; transfer immediately to a hardened filter paper\* by means of a pliable horn spatula; spread evenly over the surface of the paper and lay a second hardened filter paper over the top. Outside of the hardened filters, place several thicknesses of absorbent or filter paper, and transfer the whole to an ordinary letter press, bringing to bear all the pressure possible for about one minute. Change the outside absorbent papers and press again, repeating the operation, if necessary, until the cineol arsenate is apparently dry, and separates readily when touched with a spatula. The pressing is *not* complete when a hard mass remains which is broken up with difficulty; the method usually requires two changes of filter paper, pressing each time for about two minutes; if left too long in the press the compound may decompose. Now, transfer completely the compound by means of the horn spatula to a glass funnel inserted into a 100 cc. Cassia flask with neck measuring 10 cc. graduated in 1/10 cc. Wash the precipitate into the flask with a stream of hot water from a wash bottle, assisting the disintegration with a glass rod. Place the flask in boiling water and rotate until the compound is thoroughly broken up; add enough water to cause the cineol to rise into the neck of the flask, cool to room temperature

\* In our work we found most useful Schleicher & Schull's hardened filters No. 575, 18½ cm. diam.

and read off the volume; on multiplying the latter by 10, the percentage of cineol in the oil is obtained.

In judging whether or not petroleum ether should be added, the following rule should be observed; add enough petroleum ether to soften the cineol arsenate, so as to obtain a plastic mass; the quantity necessary never exceeds 5 cc., and decreases with oils containing less than 80% of cineol. The object of adding petroleum ether is merely to soften the hard mass and to aid in the separation of the non-cineol constituents of the oil; a large excess of petroleum ether will decompose the compound.

The above method is applicable directly to all oils containing above 50% of cineol; in oils containing lower proportions of cineol the precipitate is not solid enough to permit convenient handling; and if the cineol content drops below 25%, the separation of cineol arsenate is not quantitative. We have found that the addition of an equal volume of eucalyptol to such oils (i. e., mixing 5 cc. of the oil with 5 cc. of eucalyptol) successfully overcomes this difficulty; it then, only becomes necessary to subtract from the volume of cineol, as observed in the neck of the flask, 5 cc., and to multiply the difference by 10, in order to obtain the percentage of cineol in the oil.

*Note.*—The arsenic acid may be obtained in commerce in crystalline form; and may be dissolved in water in such proportion that the resulting solution has the S. G. of 2.173 at 25°, (corresponding approximately to 85% arsenic acid) or it may be conveniently prepared in the laboratory as follows:—

Place in a porcelain evaporating dish 50 cc. Nitric Acid S. G. 1.142, and add 60 gms. arsenic trioxide in small portions, stirring continuously; after the reaction becomes less violent, heat over Bunsen burner until the oxidation is complete and the excess of nitric acid is evaporated; test for freedom from both arsenic trioxide and nitric acid; filter and evaporate to about 100 gms. The resulting solution contains about 85% of arsenic acid ( $H_3AsO_4$ ).

In order to test the reliability of the method, we have prepared, to begin with, various mixtures of cineol with turpentine oil, and ascertained their cineol content in the manner above described, with the following results:—

1. 50 vol. % Cineol+50 vol. % Turpentine oil; found 49.5%; 50% Cineol
2. 60 vol. % Cineol+40 vol. % Turpentine oil; found 59 %; 60% Cineol
3. 75. vol. % Cineol+25 vol. % Turpentine oil; found 74 %; 75% Cineol

As stated above, we found that the application of the method to mixtures containing less than 50% cineol is not practicable; and, since adding cineol to such mixtures would have amounted simply to testing known mixtures containing a higher percentage of cineol, we have omitted this part of investigation from the line of our work as originally planned.

In order to test the applicability of our method to various oils containing cineol, we have collected from several sources a number of samples of such oils and subjected them to assaying by the arsenic acid method, comparing our results with those obtained by the Resorcinol Method.

The comparison was carried out both on original oils and on fractions distilling over between 170° and 190° C., as outlined in Schimmel & Co.'s Report, April, 1908 ("Modified Resorcinol Method").

For the purpose of determining the purity of cineol separated by the arsenic acid method, several portions of cineol, obtained in the course of assays of *original* oils, were mixed and subjected to physical examination with the following results:—

S. G. at 25° C.—0.9218; Melting Point—1° C.; Optical Rotation +0°13'.

On the other hand, being already familiar with the fact that results obtained by the Resorcinol Method on original oils are not reliable, we examined only that cineol which was obtained by the "modified Resorcinol Method," and which was thus subjected to considerable purification, at first by distilling the oil, and then by distilling with steam the resorcinol solution containing the soluble portion of the above distillate. Cineol collected in this manner from a number of Resorcinol solutions possessed the following properties:—

S. G. at 25° C.—0.9242; Melting Point—3° C.; Optical Rotation +0.7°.

The criterion of a pure cineol, according to the U. S. P., being S. G. at 25° C. —0.921 to 0.923, Melting Point—1° C.; and optically inactive, the purity of cineol obtained by the arsenic acid method, as evidenced by its physical properties, shows conclusively that none of the constituents of oil of eucalyptus other than cineol are precipitated by the arsenic acid, and that the precipitate of cineol arsenate can be freed, with comparative ease, from the non-cineol portion of the oil in question.

Results of assays made by us on eighteen samples of various oils are incorporated in the accompanying table.

Close agreement of results obtained by the arsenic acid method on original oils with those obtained on the distillate, collected between 170° and 190° C., speaks well for their correctness. An additional argument in favor of this contention is the fact that these results, from the very nature of the process, tend to be somewhat high, rather than low; observing, at the same time, that results yielded by the modified Resorcinol Method are invariably higher than those obtained by our method, we must necessarily conclude, that the latter represent more nearly the true cineol content of an oil; remembering in addition the almost quantitative yield of cineol from its mixture with various proportions of oil of turpentine when precipitated by arsenic acid (see previously), we feel justified in stating that our method gives results which represent the true cineol content within the limits of an experimental error, which in this case does not exceed 2%.

We regard the results of our experiments on known mixtures of cineol with oil of turpentine as conclusive, and our method as directly applicable to all varieties of cineol-bearing oils, for the reason that in such oils, cineol is the only constituent precipitated by the arsenic acid.

The purity of cineol, as well as the close concordance of results obtained by our method before and after distillation, show that oxygenated constituents, other than cineol, are not precipitated by arsenic acid, since fractions distilling above 190° C. carry most of such compounds, and their removal would have resulted in a percentage of cineol lower than that obtained in the assay before distillation, if the opposite were the case.

On the contrary, the numerous experiments carried out by Schimmel & Co. in assaying by the Modified Resorcinol Method, mixtures composed of cineol and fractions of eucalyptus oil distilling *below* 170° and *above* 190° C., do not prove the reliability of this method, since such mixtures do not contain the non-cineol constituents distilling *between* 170° and 190° C., some of which unquestionably are soluble in a 50% resorcinol solution; the latter may be seen from the fact that, in the large majority of oils examined by us, the Resorcinol Method (modified) gave higher results than the Arsenic Acid method.

Foot-note.—Insufficient quantity of oil to complete determinations.

An additional error in the Resorcinol Method is contributed by the solubility of oil of eucalyptus in water, which dissolves from 4% to 5% of this oil, whereas, cineol is almost insoluble; it could not be argued, therefore, that lower results obtained by our method could be due to the solubility of cineol in water.

We have adduced sufficient proof to show that the solubility of certain constituents of cineol-bearing oils must necessarily lead to a higher than actual cineol content when estimated even by the modified Resorcinol Method; it, therefore, becomes superfluous to discuss the total lack of reliability of the original Resorcinol Method in the form proposed for the inclusion into the forthcoming edition of the U. S. Pharmacopœia. Some oils, such as *eucalyptus amygdalina*, may, when assayed by this method, be accepted as a U. S. P. oil of eucalyptus, especially if a small quantity of cineol were added to them. Likewise, oils rich in oxygenated constituents may be freed from a large proportion of their cineol content by freezing and then offered in commerce as a U. S. P. product.

Schimmel & Co., in introducing the modified Resorcinol Method, assume that the fraction of oil of eucalyptus distilling between 170° and 190° carries all of the cineol contained in the oil. We admit that such an assumption may be correct in the majority of oils; we have encountered, however, some oils in which the presence of cineol was proven in portions distilling either below 170° or above 190° C. (see table, oils No. 5, No. 17, No. 18); in such oils, therefore, a certain portion of cineol would not be included into the estimation. Thus, while the modified method is, in a way, an improvement on the original method, yet at the same time, it introduces a new source of error.

Among eighteen samples of cineol-bearing oils, we found only one in which concordant results were obtained by the Resorcinol and Arsenic Acid methods (see table, oil No. 18). We regard this single exception as a final and conclusive proof of the unreliableness of the Resorcinol Method in general, and of the superiority of the Arsenic Acid Method.

#### SUMMARY.

1. Arsenic Acid forms with cineol an addition compound which is sufficiently stable for all practical purposes.

2. While the Arsenic Acid method cannot be included among those scientifically exact methods, which give results varying only slightly, even in the hands of a novice, nevertheless, we are convinced that this method is superior to any method yet proposed for the determination of cineol, being directly applicable to all cineol-bearing oils, giving results which are concordant within 2%, and representing, for all practical purposes, the true cineol content of an oil.

3. The Resorcinol Method, as slated for the U. S. P. IX, should not be adopted by the Revision Committee, for it will unquestionably lead to the introduction into commerce, of low grade eucalyptus oils; it would be far better to retain the present unsatisfactory phosphoric acid method, which undoubtedly is responsible for the fact that the majority of eucalyptus oils at present on the market possess a high cineol content, as seen from the analysis of samples obtained by us. We may suggest, however, that the Sub Committee on Volatile Oils investigate the reliability of the Arsenic Acid method with the view of including it in the forthcoming edition of the Pharmacopœia.

## NATIONAL ASSOCIATION OF MANUFACTURERS OF MEDICINAL PRODUCTS.

H. C. LOVIS, M. D.

The fourth annual meeting of this association was held at the Hotel Waldorf-Astoria on February 8 and 9.

The principal features of the meeting were the address of the President, Dr. Henry C. Lovis, the address of the Executive Committee, and the papers read by Dr. Dohme on "Paternalism in Government;" by F. B. Kilmer, on "Cultivation of Medicinal Plants," and by F. W. Bradford, on "Revision of U. S. Patent and Trade-Mark Laws."

The address of the President described the development of the world's commerce during the past year and congratulated the members upon the wisdom of our forefathers in avoiding "entangling foreign alliances," in view of the deplorable condition of Europe at the present time. He analysed the rise in prices caused by the war and said the lesson to be drawn from them, was that we should endeavor to relieve our country of its dependence upon other countries for supplies and he spoke of the necessity for protecting our manufacturers against the competition of foreign manufacturers.

The condition of our country was fundamentally sound and there was every prospect of great and profitable business for every one.

He referred to the new Currency Law as an efficient stabilizing influence to sound business conditions; to the prosperity of our railroads; to the opening of the Panama Canal and to the development of foreign markets, and strongly insisted upon our need of American ships to keep our money at home,—\$270,000,000 of which now goes into the hands of foreign companies. He congratulated the association upon the passage of the Harrison Anti-Narcotic Bill and recommended the continued representation of the Association in the National Drug Trade Conference. He advocated the support of the Price Protection measure, the Variation Clause of the Food and Drugs Act, one-cent letter postage, and extended his hearty thanks to the officers and members and to the drug journals for their coöperation in the work of the Association.

The report of the Executive Committee recommended the rebate of \$100.00 in the annual assessment; advocated the establishment of a system of compiling, registering and publishing lists of trade-names and trade-marks, and of amicable adjustment of differences relating to the same, and protested against increase of freight-rates to the Pacific coast.

The committee also recommended the passage of resolutions commending the Harrison Anti-Narcotic Bill; one-cent letter postage; the revision of the patent and trade-mark laws; and opposed any change of the variation clause of the food and drugs act; and the adoption of the German bi-chloride tablet by the Pharmacopœial Revision Committee.

It advocated changes in the laws of the states to bring them into conformity with the Harrison law and commended the efforts of the Philadelphia Drug Exchange, to remedy the injustice imposed by Section 11 of the Food and Drugs Act.

The retiring officers were re-elected for the ensuing year, and the Secretary, Mr. C. M. Woodruff, was voted an honorarium of \$500.00.

The meeting was addressed by Prof. Henry C. Hynson, Samuel C. Henry, Charles P. Tyrrell and George C. Hall.

The banquet was on Tuesday evening at the Waldorf-Astoria. President Lovis presided and the speakers were Rev. Dr. Cadman, Congressman Chandler and Luther B. Little.

## Contributed and Selected

### THE PHARMACOGNOSY OF THE MEDICINAL RHAMNUS BARKS.

E. N. GATHERCOAL, PH. G.

(Continued from page 207.)

#### RHAMNUS CALIFORNICA BARK.

(The fresh material used for this study was kindly supplied by Dr. Albert Schneider and Mr. Theodore Payne of California.)

The sections from the terminal bud exhibit a total diameter of 2 mm. of which the pith constitutes one-half, the bark 400 microns on either side and the wood circle 100 microns. The structure corresponds very closely with that of similar sections from *Rhamnus purshiana*. The mucilage sacs are especially abundant in the pith, occupying about two-thirds of the total area and apparently containing large rosettes of calcium oxalate, 30 to 60 microns in diameter, embedded in the mucilage. The contents of the pith parenchyma cells are purplish-brown in color.

In sections just below the bud the collenchyma of the outer portion of the middle bark is more distinctive than in the *Rhamnus purshiana*. Few mucilage cells are found in bark or pith, but large rosettes are very abundant and the primary bast is becoming differentiated as an almost continuous band. The phloem parenchyma cells often contain dark brown or purplish contents, as indeed do nearly all the parenchyma cells of the bark except the crystal cells. The cambium is evident and the wood circle is 200 to 300 microns wide.

At 15 mm below the bud the structure is very similar to that of *Rhamnus purshiana*.

In a four-year-old stem the bark exhibits the first evidences of secondary bast, and as yet no stone cells are present in the middle bark. The strongly differentiated character of the collenchyma is very evident.

Sections from the mature bark show a structure strikingly like that of *Rhamnus Purshiana*.

No distinction in the character of the cork layer could be determined in the two barks.

The collenchyma of *Rhamnus californica* bark observed in specimens from several plants, is larger celled than in *Rhamnus Purshiana*, these cells reaching a maximum of 100 microns tangentially by 20 microns radially, but averaging about 45 microns by 12 or 15 microns, the walls much thickened. The masses of stone cells in the middle bark are very similar in the number, size and character of their cells to those in similar sections of *Rhamnus Purshiana*. Rosettes are very abundant and the smaller prismatic crystals plentiful.

In the inner bark the secondary bast is similar to that of *Rhamnus Purshiana*, strands rather fewer celled and the fibers somewhat smaller. In inner bark 1 mm. in width, there are 6 tangential rows of bast. The medullary rays in transverse section, are from 1 to 5 cells wide, but mostly 2 and 3 cells wide. In a section 0.7

mm. long there were 28 rays, 4 of them 1 cell wide, 12 of them 2 cells wide, 10 of them 3 cells wide, 1 of them 4 cells wide and 1 of them 5 cells wide. In tangential view the rays are rather broadly elliptical, mostly 3 or 4 cells wide (60 to 100 microns) and from 10 to 30 cells long (150 to 500 microns). The widest I observed was 5 or possibly 6 cells wide, though Farwell found them 7 cells wide. As to the frequency of the rays in the two barks, they are undoubtedly more frequent in the *Rhamnus Purshiana*. In an average section of *Rhamnus Purshiana* there were 46 rays in 7 mm. as against 28 rays in 6.7 mm. of *Rhamnus californica* bark. The ray cells in transverse section are sometimes slightly elongated radially, again nearly square and again slightly elongated tangentially. In tangential view they are mostly rounded or irregular. Crystals are not present in the rays.

The waviness of the cambium edge, observed in transverse section, due to a shrinking inward at each medullary ray is a striking feature. It is best seen in rather thick sections of the bark, which has been dried and then softened in dilute alcohol, and mounted in water or phloroglucin and hydrochloric acid. But even in thin sections swollen in potassium hydrate solution this feature may yet be observed. The waviness is not seen in sections of the bark attached to the wood nor in very young bark that has been dried and afterwards softened. It was observed, however, in bark 4 years old.

Potassium hydrate solution colors at once the contents of the medullary ray cells a pinkish-red for a short distance inward from the cambium, and also the phloem parenchyma of the latest growth. After a few minutes, especially in sections cut from dried bark, and mounted directly in the potassium hydrate solution, the entire inner bark with the exception of the bast acquires the pinkish color.

#### RHAMNUS CAROLINIANA BARK.

(The material for this study was obtained from the Biltmore Nurseries of Biltmore, N. C., and from living plants in the author's garden in Oak Park.)

In transverse sections from the base of the bud of a width of 2.7 mm., the bark constitutes 540 microns and the wood circle 180 microns either side and the pith has a diameter of 1.17 mm.

The structure of these sections is very similar to sections from the base of the bud of *Rhamnus purshiana*. The epidermis consists of small, nearly cubical brown cells with some one-celled, curved or wavy trichomes.

In the middle bark, the outer portion consists of about 8 rows of small rounded parenchyma cells with living contents including chlorophyll grains. The inner portion consists of parenchyma cells containing vast numbers of rosette aggregates of calcium oxalate and with very many mucilage sacs imbedded in it.

The inner bark is narrow and consists of an outer layer of small-celled phloem and a rather wide typical cambium.

The wood circle is like that of *Rhamnus purshiana*.

The pith contains 14 mucilage sacs, the largest 450 microns across and the total occupying two-thirds of the area of the pith. Many rosette aggregates are present in the parenchyma.

In a three-year-old stem, 30 cm. below the terminal bud, measuring 6.5 mm. across, the bark constituted .65 mm. on either side.

The cork was 8 to 10 rows of cells (100 microns) in width, the cells closely resembling those of *Rhamnus purshiana*.

The middle bark is 450 microns wide, the outer portion of collenchyma, the inner portion of typical parenchyma, with a few small mucilage sacs and some rosettes. Small scattered bundles of unlignified primary bast lay at the inner edge. No stone cells are present.

The inner bark is narrow. No secondary bast has been formed.

Sections of the bark from a stem 15 mm. in diameter and 5 years old were 1 mm. wide, of which the cork layer constituted about 100 microns, the middle bark 400 microns and the inner bark 500 microns. The cork was roughened and flaked and in patches up to 18 rows of cells thick.

In the middle bark, the largest mass of stone cells observed was 300 microns long. The stone cells show pores, stratifications and lumen quite distinctly.

The inner bark contains 1 or 2 rows of small bast bundles, typically like the early *Rhamnus purshiana* bundles. The medullary rays are elliptical in tangential view, the widest observed being 4 cells wide, but mostly 2 and 3 cells wide. They are rather short, the longest observed being 20 cells long. The ray cells are mostly square or slightly elongated radially. The rays are numerous, 30 rays in a transverse section 3.4 mm. long, thus being twice as numerous as in *Rhamnus californica* bark and a half again as numerous as in *Rhamnus purshiana* bark.

No evidence of a waviness along the cambium edge was observed.

With potassa solution, the parenchyma cells of the inner bark acquire a pink-red color.

#### RHAMNUS WIGHTII BARK.—(After Hooper.)

Masses of stone cells are found in the middle bark and rosette aggregates of calcium oxalate crystals are abundant in the parenchyma cells.

The inner layers consist of pale yellow bast fibers running through a mass of cells containing yellow brown color. The bast bundles are surrounded by numerous rhomboidal crystals. The medullary rays and inner cellular layers are filled with starch and a yellow coloring matter acquiring a brilliant red with potash solution.

#### RHAMNUS FRANGULA BARK.

(The fresh material used for this study was collected in the dormant season from cultivated plants in the south parks in Chicago and in the author's garden in Oak Park, Illinois.)

The sections obtained from the terminal bud correspond very closely with those

(Detail of cuts on succeeding page.)

#### RHAMNUS FRANGULA AND RHAMNUS CATHARTICUS

Fig. 23. Transverse section of the bark from a 9-year-old stem of *Rhamnus frangula*. A, outer bark; B, middle bark; C, inner bark. 1, cork, the outermost rows compressed; 2, collenchyma; 3, middle bark parenchyma with numerous rosettes of calcium oxalate crystals; 4, the earliest secondary bast; 5, secondary bast of later growth with accompanying crystal fibers; 6, phloem consisting mostly of parenchyma with some rosettes of calcium oxalate; 7, medullary ray, practically free from crystals; 8, cambium. (X 200, reduced  $\frac{1}{2}$ .)

Fig. 24. From the inner bark of *Rhamnus frangula*, in transverse view. 1, bast fibers; 2, crystal fibers; 3, phloem parenchyma, one cell showing a rosette aggregate, another with living cell contents and a third with pores in the bottom wall. (X 600, reduced  $\frac{1}{2}$ .)

Fig. 25. The inner bark of *Rhamnus frangula* in tangential view. 1, medullary ray; 2, phloem parenchyma; 3, bast fibers; 4, crystal fibers. (X 600, reduced  $\frac{1}{2}$ .)

Fig. 26. Transverse section of the bark *Rhamnus catharticus* from a 4-year-old stem. A, outer bark; B, middle bark; C, inner bark. 1, cork, many rows of narrow cells much elongated tangentially; 2, collenchyma of a few poorly differentiated rows; 3, parenchyma with some calcium oxalate rosettes; 4, unlignified primary bast; 5, lignified secondary bast with crystal fibers; 6, phloem parenchyma; 7, medullary ray; 8, cambium. (X 200, reduced  $\frac{1}{2}$ .)

Fig. 27. Tangential view from the outer and middle barks of *Rhamnus catharticus*. 1, cork; 2, phloem; 3, parenchyma with rosette aggregates; 4, primary bast in interweaving strands. (X 600, reduced  $\frac{1}{2}$ .)

Figs. 28 and 29. Tangential views from the inner bark of *Rhamnus catharticus*. 1, medullary ray; 2, bast fiber; 3, crystal fiber; 4, phloem parenchyma with strongly beaded walls and occasional rosettes of calcium oxalate crystals. (X 600, reduced  $\frac{1}{2}$ .)

Fig. 23

Fig. 26

Fig. 25

Fig. 27

Fig. 28

Fig. 29

from *Rhamnus purshiana* bark, likewise no distinctions could be made in sections from each plant just below the bud, except possibly a somewhat less number of mucilage sacs and of rosette aggregates of calcium oxalate in the *Rhamnus frangula*. It is noteworthy, however, that already, in these sections from the base of the bud, cork has made its appearance, for in some portions of the section three layers of typical cork cells were present beneath the epidermis, in other portions none, though a phellogen can be distinguished throughout the whole circumference. The cork cells are mostly 15 microns tangentially, 8 to 10 microns radially, thin walled, the outer row with the walls red-brown in color.

In sections 2 mm. below the bud, the epidermis, with the abundant brown trichomes; the parenchyma, mucilage sacs, unlignified primary bast and rosette aggregates of the middle bark; the thin phloem layer and the medullary rays of the xylem all correspond with similar tissues in similar sections of *Rhamnus purshiana*. The brown-walled cork is in a continuous layer 3 to 5 cells wide.

At 5 cm. below the bud, the outer bark is 50 to 90 microns wide, the middle bark 200 microns across, the inner bark 160 microns wide, the wood circle 360 microns wide and the pith 1170 microns in diameter: total diameter of the stem 2.75 mm. There are no changes of note except a slight thickening of the cork, phloem and xylem layers. The medullary rays of the wood are lignified.

At 15 cm. below the bud the wood is of two seasons' growth, the width of the xylem circle being nearly 1 mm., the pith 1 mm. in diameter and the bark nearly  $\frac{1}{2}$  mm. thick. There are practically no changes in the bark. In another specimen from a three-year-old stem of a total diameter of 4.5 mm. the cork is irregular, up to 100 microns thick, the middle bark is 200 microns thick and the inner bark 200 microns thick. No secondary bast nor stone cells are present.

In a four-year-old stem the first evidence of secondary bast is found.

In a nine-year-old stem sectioned through a lenticel, the bark measures 1.07 mm. in thickness, of which 240 microns is outer bark, 200 microns middle bark and 630 microns is inner bark. The outer bark consists of exfoliating layers of small dark red cork cells intermixed with colorless cork cells and of a typical lenticel structure. The middle bark of parenchyma contains interweaving strands (one circle only) of non-lignified primary bast. No stone cells are present. The inner bark contains 5 irregular circles of bast bundles with the accompanying crystal fibers. The medullary rays as seen in tangential view are either a single row of cells or a narrow biconvex mass 2 or 3 cells wide. Small rosette and prismatic crystals in the parenchyma are very abundant. A few starch grains 3 or 4 microns in diameter are found in the parenchyma of medullary ray, phloem and middle bark.

Samples of the commercial drug gave sections very similar to the ones just described. The outermost layer of brown cork is seen to consist of several rows (8 to 20) of small rectangular cells, many with purplish contents, arranged one behind another in regular radial rows. The middle bark is of rounded or oval parenchyma cells with rather thin cellulose walls and granular contents and, it is worthy of note, that the parenchyma cells in the dried, cured bark often possess deep brown or purplish brown contents. Many prismatic crystals and rosette aggregates are found in the cells of this layer. The inner bark is traversed radially by the rather numerous, nearly straight medullary rays up to 3 cells wide and

longitudinally by the conspicuous bast bundles with from 2 or 3 to 30 or 40 bast fibers in each. The individual fibers are narrow, thick walled, the cavity but a line and strongly lignified. Adherent to each bundle of bast are the typical crystal fibers.

Powdered *Frangula*, macroscopically, very closely resembles powdered *Cascara*, for in many samples of each powdered drug observed, the resemblance in color, odor and taste was so striking that they could not be differentiated by these means. Microscopically, nearly all the tissues in powdered *Frangula* closely resemble the corresponding tissues in powdered *Cascara*, though there is one very characteristic tissue, the stone cells, in *Rhamnus Purshiana* not present at all in *Frangula*. Therefore, it is not difficult to distinguish between these powders when separate, nor to detect *Cascara* in *Frangula*. It is somewhat more difficult to detect *Frangula* admixed with *Cascara*. However, the purplish contents of many of the cork cells of *Frangula* give to most of the fragments of cork, especially in a mount in chloral hydrate solution, a bright purplish color, while the fragments of cork from *Rhamnus Purshiana* remain of a brown or reddish-brown color.

#### RHAMNUS CATHARTICUS BARK.

(The material used for this study was obtained from cultivated plants from the Missouri Botanical Gardens of St. Louis, from the south parks of Chicago, and from plants in the author's garden in Oak Park, Ill.)

The stem of *Rhamnus catharticus* does not often possess a terminal bud. After the growth for the summer has ceased the terminal bud usually dies and that portion of the stem, 5 to 40 mm. long, projecting beyond the uppermost pair of axillary buds, hardens and becomes more or less pointed and thorny.

In transverse sections from about the middle of the lateral bud the epidermis corresponds to the similar epidermis of *Rhamnus purshiana* except that it is almost devoid of trichomes. A few appressed pairs are noted on the bud scales. The parenchyma of the middle bark consists of rounded cells up to 30 microns in diameter with thin, cellulose walls, cytoplasm, nucleus, chloroplasts and an occasional rosette aggregate of calcium oxalate. No mucilage sacs are present. Evidences of a primary bast are seen. Neither medullary rays nor cambium are present. The pith cells contain many large rosettes of calcium oxalate, but no mucilage sacs are present. Total diameter 1 mm.: cortex 175 microns wide, wood circle 125 microns wide, pith 400 microns in diameter.

In sections from the base of the bud the structure of the stem is very similar to that just described, except that the wood circle is wider, up to 200 microns, the xylem masses contain 10 or 12 tracheal tubes in a radial row and medullary rays are distinct.

The stem just below the uppermost pair of lateral buds has already attained a considerable maturity, as is evidenced by a growth of cork, of secondary bast, phloem and medullary rays and a lignification of the pith. The following is a brief description of sections 1 mm. below the base of the uppermost pair of lateral buds.

Epidermis—cells 15 microns radially, 20 microns tangentially, cuticle 8 to 10 microns thick. Cork—8 to 10 tangential rows of cells have a total width of 30 microns radially, the cells being 15 to 75 microns tangentially, the lumen but a

line and the walls thin and brown. Outer parenchyma—slightly collenchyma-like, the cells 15 microns radially, 15 to 30 microns tangentially. Inner parenchyma—isodiametric, up to 30 microns in diameter the cell contents brownish in color. Primary bast—in masses much elongated tangentially, 2 or 3 cells wide radially, the cells seldom exceeding 15 microns in diameter, somewhat compressed, with very thick cellulose walls. Secondary bast—1 or more rows of small bundles containing 3 or 4 to 15 or 20 cells tangentially and 1 to 3 cells radially, the fibers seldom exceeding 12 microns in diameter, with thick lignified walls. Crystal fibers—abundant; in structure and location the same as in *Rhamnus purshiana*. Medullary rays—distinct, 1, 2 or 3 cells wide. Phloem—parenchyma abundant; sieve and companion cells in small patches, the sieve plates difficult to differentiate. Wood circle—300 microns thick.

A transverse section at the base of the season's growth, measuring 2.3 mm. across, corresponds very closely to the above description, except that the wood ring is 400 microns in thickness.

The bark from a stem four years old measured 0.7 mm. in thickness. The structure of this bark differs but little from that described above, though the following changes may be noted: Cork—somewhat thicker and occasionally roughly split longitudinally. Primary bast—in small bundles rather widely separated by parenchyma. Secondary bast—in 3 irregular tangential rows. The prismatic crystals of the crystal fibers are very prominent. Rosette aggregates 10 microns across are common in the phloem.

Bark that would correspond with commercial bark if the drug was on the market may be described as follows: A specimen 2 mm. thick possessed a dense cork layer from 100 to 300 microns thick, dark yellow-brown in color and much fissured and flaked. The middle bark, 200 microns thick, consisted mostly of chlorophyll-bearing parenchyma, a few of the outer rows somewhat collenchymatous, with a few rosettes, a few widely separated primary bast strands and no stone cells. The inner bark 1620 microns wide at the thickest part, had 18 tangential rows of secondary bast, the character of each bast strand typically that of

(Detail of cuts on succeeding page.)

#### RHAMNUS CHLOROPHORUS, CAROLINIANA, CROCEUS, AND CALIFORNICA.

Fig. 30. Transverse section of mature bark from *Rhamnus chlorophorus*. A—outer bark, B—middle bark, C—inner bark. 1—cork, the cells narrowed radially and elongated tangentially and the outermost rows compressed; 2—collenchyma; 3—parenchyma; 4—unlignified primary bast; 5—lignified secondary bast with accompanying crystal fibers; 6—phloem, consisting mostly of parenchyma and bearing no crystals; 7—medullary ray with numerous rosette aggregates of calcium oxalate; 8—cambium. (X 200, reduced  $\frac{1}{2}$ .)

Fig. 31. Transverse section of the bark from a 5-year-old stem of *Rhamnus caroliniana*. A—outer bark, B—middle bark, C—inner bark. 1—cork, the outermost rows compressed; 2—collenchyma, strongly differentiated and with thickened cellulose walls; 3—parenchyma with rosettes and prisms of calcium oxalate; 4—masses of stone cells; 5—unlignified primary bast; 6—lignified secondary bast with crystal fibers; 7—phloem, consisting mostly of parenchyma and bearing small rosettes; 8—medullary ray without crystals; 9—cambium. (X 200, reduced  $\frac{1}{2}$ .)

Fig. 32. Transverse section of the mature bark of *Rhamnus croceus*. A—outer bark, B—middle bark, C—inner bark. 1—cork, the outermost rows compressed; 2—collenchyma, tangentially elongated cells with thickened cellulose walls; 3—parenchyma with large rosettes of calcium oxalate crystals; 4—unlignified primary bast; 5—lignified secondary bast with crystal fibers, the bundles mostly separated from the surrounding parenchyma; 6—phloem, the cells sometimes compressed and consisting mostly of parenchyma with occasional rosettes of calcium oxalate; 7—medullary ray without crystals; 8—cambium. (X 200, reduced  $\frac{1}{2}$ .)

Fig. 33. Transverse section of the bark from a 10-year-old stem of *Rhamnus californica*. A—outer bark, B—middle bark, C—inner bark. 1—cork, the outermost rows compressed; 2—collenchyma, strongly elongated tangentially with much thickened walls; 3—parenchyma with numerous rosettes and prisms of calcium oxalate; 4—a group of stone cells; 5—unlignified primary bast; 6—lignified secondary bast with crystal fibers; 7—phloem parenchyma; 8—medullary ray. (X 200, reduced  $\frac{1}{2}$ .)

Fig. 34. Transverse section of the inner bark of *Rhamnus californica* stem. 6, 7 and 8—same as in Fig. 33. 9—the cambium, the edge showing the waxiness characteristic of this bark. (X 200, reduced  $\frac{1}{2}$ .)

the bast in *Rhamnus Purshiana*, though the bundles in *Rhamnus catharticus* are smaller, being mostly less than 200 microns (about 12 fibers) tangentially and less than 60 microns (4 fibers) radially, most of them but 2 fibers radially. The bast strands are inclined to unite with one another in each row and even form extensive tangential layers penetrated by the medullary rays. The phloem masses are distinct, though the sieve plates are differentiated with difficulty, most of the phloem cells being parenchyma, somewhat elongated longitudinally and with strongly beaded walls. Many cells with yellow contents are scattered in the phloem parenchyma and practically all the cells of medullary ray and phloem acquire a bright red color with potassa solution. The medullary rays are seldom 3 cells wide, mostly 2 cells or but 1 cell wide. The cells are elongated tangentially (up to 45 microns) rather than radially (up to 20 microns). In the tangential section of the bark, the rays are broadly elliptic because of this tangential elongation of the ray cells and because of the shortness of the rays longitudinally, about 6 to 10 cells.

It is to be noted that the bast strands easily separate from the surrounding parenchyma and in longitudinal section or in the powder the interlacing bundles appear in long masses with numerous fusiform spaces through which have passed medullary rays.

#### RHAMNUS CROCEUS BARK.

A specimen of bark 2.5 mm. thick possessed a rather thin cork layer, about 100 to 200 microns thick, rough and flaked and with cork cells nearly square or somewhat elongated tangentially (15 to 30 microns long). The middle bark (320 microns wide) consisted of an collenchymatous portion and an inner parenchyma layer. Rosettes and prisms of calcium oxalate were very abundant. There were no stone cells, but a few widely-separated strands of non-lignified primary bast.

The inner bark, 2 mm. wide, contained 18 tangential rows of secondary bast bundles, each strand like that of *Rhamnus Purshiana* bark. The bast bundles were from 8 to 30 cells (350 microns) tangentially and from 1 to 5 cells (80 microns) radially. The crystal fibers were very abundant, sometimes 2 rows about a bast bundle. The medullary rays, in tangential view, were elliptical, though not so broad as in *Rhamnus catharticus*, from 6 to 12 cells (100 to 250 microns) longitudinally and from 1 to 3 cells (20 to 80 microns) wide, though mostly 2 cells wide. The cells were nearly isodiametric, sometimes slightly elongated tangentially or radially, and nearly devoid of rosette crystals. In transverse view the rays were rather indistinct, but could be followed. There were 30 rays in 6 mm. of bark.

The phloem consisted mostly of parenchyma cells elongated longitudinally with square ends and non-beaded walls. Often the cells were much compressed radially between the bast bundles. Crystals were rather few except in the outer portion of the inner bark. All the parenchyma cells of the inner bark acquired a bright red color with potassa solution.

As in *Rhamnus catharticus* bark the bast strands easily separate from the surrounding parenchyma. In transverse section many of them fall out, leaving elliptical spaces and in longitudinal section and in the powder the interlacing bundles are in long masses with elliptical spaces through which passed medullary rays.

## RHAMNUS CHLOROPHORUS BARK.

The dried bark from old stems soaked in dilute alcohol and sectioned, exhibited the following structure:—

Outer bark—100 to 300 microns thick, consisting of a brown cork layer supporting externally some thin lichen growths and internally a narrow disrupted phellogen. The cork cells are much elongated tangentially up to 75 microns, narrow radially, 8 to 10 microns, thin-walled, suberized.

Middle bark—200 microns thick, consists mostly of tangentially elongated collenchyma cells, up to 100 microns, but not more than 15 microns radially, with thick cellulose walls and long narrow cavities with brownish, granular contents. An occasional strand of much compressed unligified primary bast is seen. No stone cells are present. Some rosette aggregates of calcium oxalate.

Inner bark—up to 1 mm. thick. Contains very many bundles of strongly lignified secondary bast separated by interlacing bands of phloem and indistinct medullary rays. There were 12 tangential rows of bast bundles in an inner bark 0.9 mm. thick.

The bast bundles are elliptic in transverse view, 2 to 5 cells wide radially and 5 to 20 cells tangentially, the fibers not more than 15 microns thick and each bundle invested by a single row of crystal fibers, typically those described under *Rhamnus Purshiana*. The phloem does not display sieve tubes well, but apparently consists mostly of parenchyma, the cells of which are rounded or oval, somewhat compressed tangentially and elongated longitudinally. Because of the number and close proximity of the bast strands and the indistinctness of the medullary rays, the narrow bands of phloem appear as though interweaving around and between the bast strands. The medullary rays are very indistinct in the transverse view, though they can be traced by a very slight difference in the shape of their cells from the surrounding parenchyma cells and by the presence of calcium oxalate rosettes. These crystals are numerous in the rays, but very scarce in the other tissues of the inner bark. In the tangential section the rays are elliptic in shape, 2, 3 or 4 cells wide at the broadest part, 10 to 30 cells long. They penetrate the bast strands and phloem parenchyma.

## FRESHLY PRECIPITATED RESINS IN AQUEOUS MEDIUM.

SAMUEL T. HENSEL, PH. G.

The object of this paper is to serve the two-fold purpose of suggestion to some future investigator, and to present a practical application of an observed phenomenon.

It is prompted by the reading of a query sent to the editor of one of our leading trade journals, which appears in the current issue of December, just received. The correspondent asks for information concerning the method to be employed in the preparation of a mixture of rose-water, glycerin and tincture of benzoin, a well-known and popular form of toilet cream.

Ten years ago, or more, the writer observed that the various resinous tinctures of the United States Pharmacopœia, such as the tinctures of benzoin, myrrh, asa-fetida, etc., were differently affected by the same volume of water; the permanence of suspension of the freshly-precipitated resin, depending upon the method employed in bringing these two substances together. The two following experiments were performed at that time.

*Experiment No. 1:*—Three ounces of distilled water were introduced into a four-ounce prescription bottle, and one half fluid-dram of tincture of benzoin was then carefully added, drop by drop, shaking the contents of the bottle vigorously after the addition of each drop.

Suspension of the precipitated resin, was apparently complete, until the addition

of the tenth or twelfth drop, when minute masses of agglutinated resin were observed floating throughout the mixture; these increased in size and number until apparently the greater part of the resin-content of the tincture was thrown out of solution.

The results obtained in this experiment prompted the following:

*Experiment No. 2:*—Three fluid ounces of distilled water were introduced into another four-ounce prescription bottle, and in this case, the procedure was the reverse of experiment No. 1, the entire one-half fluid dram of the tincture of benzoin being rapidly delivered upon the surface of the water contained in the bottle and permitted to rest upon the surface for the period of about five seconds, and then the mixture was vigorously shaken, as before.

The result in this case was the complete suspension of the resin, producing a permanent emulsion which showed no sign of change after the period of ten days.

More recently, in making a practical application of the result of these experiments, I find that as much as one and one-half fluid ounces of tincture of benzoin, may be delivered into the volume of twelve fluid ounces of water, in the manner described in experiment No. 2, and, if immediately incorporated with an equal volume of glycerin, a white and permanent emulsion will result.

Naturally, when a new or strange condition is observed, the question arises in the mind of the investigator, "What is the cause," and his hypothesis, then formed, will frequently assume a working phase which will lead him into a rational procedure, which will finally result in the solution of his problem.

I am not in a position at present to give the results of a systematic scientific investigation, but I have nevertheless formulated an opinion which may be of service to some other investigator, and help him to the solution of a problem of perhaps greater importance.

It is a well known fact that when alcohol is mixed with water, there is an immediate evolution of heat, which in the terms of physical chemistry, is the "Heat of solution," and is of positive sign (exothermic).

It is also known that water is porous, as has been demonstrated both by physicist and chemist, in recent years.

Now, in the case of experiment No. 1, the nuclei or minute sub-division of resin, as quickly as they are formed, are subjected to the influence of the heat of solution referred to; their surfaces becoming areas of adhesion, and, as their number increase with each successive drop, the subsequent agitation to which they are subjected has the effect of bringing the particles closer together. The element of time now intervenes, and, as they have increasingly shorter distances to travel,—their surfaces being still thermally affected,—they adhere, to form the masses observed in the experiment.

In the case of experiment No. 2, owing to the sudden development of the heat of solution, the inter-spaces of the water are thermally affected to the extent that numerous and infinitely small channels or tubes are created at the surface, into which the resin is temporarily deposited, which again, when vigorously shaken, are broken up into infinitely small particles, whose comparatively limited area are suddenly chilled, and thus rendered incapable of adhesion. Hence, a permanent suspension of the resin.

## THE DEBT WHICH MEDICINE OWES TO SECRET PREPARATIONS.

---

 OTTO RAUBENHEIMER, PHAR. D.
 

---

A great many preparations are in daily use as household remedies, and even as official preparations in the U. S. P. and N. F., which originated as secret medicines. The history and the evolution of these remedies is very interesting, and the writer, as teacher of History of Pharmacy in one of our Colleges, takes special interest in this subject, and takes pleasure in presenting the origin of some of these remedies.

The reason that some of the proprietary remedies are called "Patent Medicines" is that they were originally patented, and I herewith present a list of some of the remedies still used to-day together with the date when they were patented:

Haarlem Oil.....	1672	John Hooper's Female Pills.....	1743
Godfrey's Cordial.....	1720	Dr. James' Powder.....	1747
Bateman's Pectoral Drops.....	1726	Roche's Embrocation.....	1803
British Oil.....	1742	St. John Long's Liniment.....	1820

All of these old remedies are still extensively used to-day, in spite of the fact that some of them have been patented almost two hundred and fifty years ago. The "Female Pills" originated by John Hooper, apothecary and man-midwife as he was called, continue to have a very large sale.

Physicians and pharmacists have lent a helping hand in originating preparations which have greatly enriched our *Materia Medica*, for instance: Paregoric was originated by Dr. Le Mort, Professor of Chemistry at the University of Leyden, and the predecessor of the immortal Boorhaave, the founder of the celebrated Vienna Medical College. Wine of Opium originated by the celebrated English physician, Sydenham, Comp. Powder of Rhubarb originated by Dr. James Gregory, Professor of Medicine at Edinburgh. Calamine Ointment, originated by Dr. Daniel Turner, a celebrated surgeon at London. Powder of Ipecac and Opium, by Thomas Dover, doctor and pirate. In connection with this, permit me to point out that even in those early times some of the doctors were pirates! Solution of Potassium Arsenite, by the apothecary, Thomas Fowler. In connection with Fowler's solution, I beg to state that he originally kept its Arsenic content secret and named it *Mineral Solution*.

Perhaps the most important of this class is *Rochelle Salt*, which was accidentally discovered by the French apothecary, Pierre Seignette in 1672, and the composition of which was kept secret for almost sixty years, until at last in 1731, two French pharmacists made an analysis.

*Sodium Bicarbonate* was introduced into medicine by the Berlin apothecary, A. W. Bullrich, as his "Universal Salz" in 1840. Let me point out that Bullrich "threw the bull" for a number of years and at the same time succeeded in getting "rich" from it. Nevertheless, pharmacy and medicine owe a great debt to Bullrich for introducing this chemical into therapy.

Many of the secret remedies became celebrated panaceas and obtained such fame, and did such an amount of good that the formulas of same were bought by the monarchs in those days at a very fancy price. This is an entirely different

procedure to what the present Board of Health of our great city of New York pretends to do!

The following are some of the examples:

Louis XIV, King of France, bought the following: Helvetius' Ipecac Remedy in 1686 at 1000 Louis d'or; Glauber's Kermes Mineral in 1720 at a fancy price; Talbor's Cinchona Remedy in 1780 at 2000 Guineas.

Louis XV bought the formula for La Mothe Tincture, giving him a pension of 4000 Livres a year.

Louis XVI purchased Mme. Nouffer's Tapeworm Remedy, at 18,000 Livres;

King Charles II of England bought Dr. Goddard's Drops for 6000 pounds Sterling, and Empress Catharine II of Russia invested in Bestuscheff's Tincture, 3000 Rubles.

It will no doubt interest the readers of the Journal A. Ph. A. to learn of a striking example of the effects, the bad effects, of the publication of a formula. The specific is that of *Warburg's Tincture*.

Originated in 1840 by Dr. Carl Warburg, an Austrian physician, it soon proved to be a specific in Malaria and Ague. In spite of being a secret remedy, the Austrian Imperial Health Board in 1848 ordered this tincture to be kept in stock in *all* the pharmacies of the Empire, and even established at Vienna, a central depot at which the preparation was manufactured under the supervision of the inventor.

The fame of Warburg's Tincture spread as far as India, and it was considered as one of the necessities of all British soldiers going to that country. In consequence of this, the preparation obtained a tremendous sale. At last Dr. Warburg was persuaded, in fact pressed to disclose his secret formula. Warburg did so. What was the consequence? Warburg, the originator of the celebrated Anti-periodic Tincture, died in poverty.

The author does not claim that this subject is exhausted and hopes to be able in the near future to find the time to make a complete compilation of the origin, the history and the evolution of the U. S. P. and N. F. preparations.

## THE RELATION BETWEEN MEDICINE AND PHARMACY.\*

WILFRED M. BARTON, M. D.,

Associate Professor of Medicine in the Medical Department of Georgetown University.

In the first place, I shall take it that we are met here to night, physicians and pharmacists, not merely for self glorification, but for the purpose of seriously discussing the true existing relations between our two professions, Medicine and Pharmacy; to find out whether we are drifting apart, developing a closer union, or merely maintaining a *statu quo* which we have inherited from our immediate

\* Read at a joint meeting of the Therapeutical and Pharmaceutical Societies of Washington, D. C., June, 1911.

predecessors. In any event we would like to know exactly what is the trend of affairs concerning our relations, the principal factors upon which this relation depends and, of course, we would like to find a way to improve these relations whatever they may be.

Primarily, I may say, what is no doubt evident to any one who thinks about it, that such a social re-union as this one to-night cannot but be productive of good results, because social intercourse between different, nay even differing interests, is the surest method of enhancing their mutual adjustment. We are, of course, not arbitrating anything, for it has not appeared that we have any differences to adjust; but the mere getting together of men engaged in related pursuits, is a sure way of enlarging their sympathies, and of widening their field of vision. What was before of only academic interest in the mind becomes vitalized by humanitarian and sentimental forces. We see not only a related science with all its technical accoutrements, but a brother human being working away and devoting his life to it. So, I would suggest, on this account, that such meetings as this be made more frequent and more general. The state pharmaceutical and medical societies should work out a plan of closer affiliation. When the American Medical Association meets annually in a certain place, there also and at the same time should the American Pharmaceutical Association meet. Could this be done some very interesting events would take place, science would be advanced, disputes would be adjusted, professional ethics enlarged, quackery and charlatanism would receive blows from the effects of which they would sooner succumb. There is, however, one thing which serves at least periodically to bring physicians and pharmacists in this country closer together, and that is, the *Pharmacopœia*. The decennial revision of this great book, which has gone through eight editions, with a ninth one soon to appear, provides the only formal opportunity, at present indulged in, for closer affiliation and interchange of views between the two professions. The Committee on Revision, composed as it is of distinguished representatives from both, whose work extends over a period of years, tends to enlarge, to dignify, and to perpetuate, the bond of sympathy which exists between them.

It is always best to be methodical and if I were submitting any formal thesis upon the relations of Medicine to Pharmacy I should like to begin with a review of the historical aspects of this relation.

The *pharmacopœia* forms the closest link between Medicine and Pharmacy. The scientific state of both at any given period, since the middle of the 16th century when the first *pharmacopœia*, that of Valerius Cordus, appeared (1540), may be read in its pages, and is reflected by its contents. The first London *Pharmacopœia* appeared in 1618. It contained 1960 remedies, of which there were 1028 simples, 91 animal products and 271 vegetable products. There were some very strange substances in it, many of which to us now appear vile and disgusting, and it is hard for us to believe that intelligent men ever attributed therapeutic value to these things, such for example as worms, dried viper lozenges, dried fox's lung, powdered precious stones, oils of ants and wolves. The edition of 1650 contained moss from the skull of a victim of violent death, crab's eyes, animal feces, cock's comb, human perspiration, saliva of a fasting man, human placenta, wormian bones from executed criminals, and other items too numerous

to mention, and, certainly revolting, when one considers the proposition of swallowing them.

But even our present Pharmacopœia contains many useless, if not so disgusting, things, and if William Heberden, in 1745, was forced to make an onslaught upon the superstitions which retained animal feces and human placenta in the pharmacopœia in his day, and did not find it an easy proposition to secure their elimination, so also, at the present time, it is no easy matter to secure the deletion of many utterly worthless substances from the modern book. I often wonder whether future generations will not look down upon our far-famed ninth revision quite as ludicrously in some respects as we look back upon the English pharmacopœias of 1650. It is unfortunate, it seems to me, that the pharmaceutical factions who are concerned in revising our Codex, are usually opposed to the idea of deletion and use their influence toward the retention of substances in the book which to the modern physician who is acquainted with the progress of pharmacological and experimental therapeutic research seem entirely superfluous, and scientifically degrading. Those who are interested in this aspect of things we are discussing should read a paper by Doctor O. T. Osborne on "The Absurdities and the Commercialism of the Proposed 9th Decennial Revision of the U. S. Pharmacopœia." Though he does not say so categorically, yet by implication, the blame is put largely upon the Pharmaceutical representation in the executive committee on revision, eleven out of the sixteen of which are pharmacists. Out of one hundred and fifty-eight drugs and preparations, proposed to be deleted from the 9th revision by the sub-committee on scope, seventy-nine were voted back by the pharmaceutical influences prevailing in the executive committee.

One of the great functions of the pharmacopœia is to keep constantly in view the close relations between Medicine and Pharmacy, which without it might by some be totally forgotten or ignored.

I had not intended to say so much about history and the pharmacopœia, but there is one more historical reference which will serve to clarify in a way, the reasons for the existence of a special feud between Medicine and Pharmacy which has been going on for about four hundred years. This is the dispute over the so-called "prescribing by druggists." According to history, the grocers were the original drug merchants in England. In 1606, during the reign of James I, the apothecaries were incorporated, and succeeded in obtaining from the grocers this coveted monopoly. This aroused the ire of physicians, because, no sooner were the druggists invested with the power to compound and to sell all medicines, than they discovered that money could be made in easy fashion by selling direct to the people on their own responsibility. Thus began "drug dispensing" and with it a war which has continued, more or less openly, to the present day. Physicians and druggists continued to wrangle on this point in England for half a century, when, in 1665, the Great Plague broke out in London. The apothecaries stayed at their posts, while the doctors, including the great Sydenham himself, fled for their lives.

It seems that even at that time, however, the druggists were much criticized for their extortion, and the huge prices they charged for much worthless stuff may have been the origin of the erroneous idea, still prevailing among the laity,

that the druggist makes anywhere from 500 to 1000% on his wares. On certain drug bills of the above-mentioned period in England, are listed 4s. for a glass of wine of iron, 3s. 6d. for a "purge for his worship," 3s. for a son's purge, 4s. for a fumigating powder. It is known that as much as 30s. was paid for one pill, and 6£ for a pill and a decoction. The pharmacists made more out of their cases than the physicians. But as a matter of fact we all know that extortion is not a monopoly of druggists and that some doctors have been known to indulge in a little of it, by way of exercise and showing what they can do.

There is no doubt that Pharmacy is receiving less and less attention in the medical curriculum at the present time. Does this mean that pharmacy is being gradually considered less and less important, to the educated medical man, or does it mean rather that pharmacy is developing so fast that it can no longer be properly covered, even synoptically, in a medical course? In this connection, we may profitably repeat what Cushny has written in his classical work on Pharmacology. He says "another subject which now occupies a much less prominent position in medical study than formerly is Pharmacy, or the art of preparing drugs for therapeutic use. Some general knowledge of the methods used, is no doubt indispensable to the educated physician, but the details may be left to the pharmacist. Pharmacy will probably occupy a still more subordinate position in medical education, as the tendency to include only one or two drugs in a prescription becomes more wide-spread. As long as a dozen or more components went to make one mixture, it was of importance to know their solubility and their interaction, but with the decay of the complex prescription the study of pharmacy by medical students has certainly become less imperative."

This appears to be a true representation of the facts, and it may have the effect of separating the physician and the pharmacist more and more, if some counter-acting influences are not called into play. It seems to me that all Colleges of Pharmacy should be closely affiliated with medical schools, just as the Dental school is closely associated. Dentistry bears the same relation to surgery that pharmacy does to medicine, and therefore the latter two should never be allowed to drift apart. The medical student is not expected to learn any dentistry, and according to Cushny and most modern pharmacologists, he should not be required to learn much pharmacy, but in order that all these cognate and correlated branches in our great medical science and art may thrive best, individually and collectively, and that the members of these sister professions may have a more adequate knowledge of their interdependence and correlation, they should all be taught in our universities as far as possible under the medical college roof. Here the great ideals which form the moral and ethical foundation of medicine can be inculcated, in the minds of all who are engaged in it, or any of its branches. Every hospital should have its expert pharmacist. Questions are continually arising which only a skilled chemist pharmacist can decide. I saw a good example of this fact in reading an article in a French journal recently by Crouzon on the use of ethero-camphorated oil. It seems that on the continent of Europe the old camphorated oil is much used, by hypodermic injection, in the treatment of senile pneumonia, collapse adynamia from diverse causes, shock, peritonitis, etc. Large doses are employed, 20 to 50cc. more or less frequently repeated. These doses produce ugly lumps in the muscular tissues and even ab-

cesses occur. Cruzon desired to know whether these disadvantages were inevitably inherent in the treatment itself, or whether they could be obviated by altering in some way the solution of the oil. This question he put to Viron, the expert pharmacist-chemist of the Saltpetriere Hospital, where both of them had worked. Viron suggested an ethero-oily solvent for the camphor in the following formula:

Camphor .....	1 gm.
Anesthetic Ether.....	1 cc.
Alcohol-washed sterilized olive oil.....	10 cc.

This solution, which must be prepared in a special way to prevent evaporation of ether, was found to be an agreeable substitute for the old solution and no lumps were formed. This, of course, is only a trivial example, but it illustrates the fact that there are certain problems in hospital work which can only be solved by the pharmacist, who is in this respect the true co-worker of the physician.

On the continent of Europe the colleges of pharmacy are regarded, and properly so, as integral parts of the University, and kept in closer affiliation with the medical schools than is attempted in the United States. There is no lack in number of pharmacy schools in this country, however. Although in 1840 there were only three, now there are about fifty. The student of pharmacy is often a college-bred man and the standard of pharmaceutical education is being gradually raised as in the medical schools.

It should be kept continually in mind, that pharmacy is a branch of medicine, a true specialty, and its teaching should always be conducted in colleges closely affiliated with medical schools. It will be seen thus, that our contention is, that the relation between Medicine and Pharmacy is very close and must remain so. The science of medicine is founded upon anatomy, physiology and chemistry, while pharmacy is founded upon chemistry and physics. Progress in both depends, therefore, entirely upon progression in these fundamental sciences. Of course, from the standpoint of commercialism, there will be some disputes and antagonism between Medicine and Pharmacy, but from the standpoint of true science there can be but the closest union.

It is to be hoped that the standards of education in pharmacy will continue to be raised higher and higher commensurate with the developments in chemistry, pharmacy and medicine.

If this is done the pharmacist will become a still more indispensable associate of the physician especially in the direction of analytical and pharmaceutical chemistry and perhaps also pharmacology. Such meetings as the one we are holding to-night will do good, affording as they do an opportunity of emphasizing what we should not allow to be forgotten, the close relation between the sciences of medicine and pharmacy.

WHAT INSTRUCTION OUGHT MEDICAL COLLEGES TO GIVE IN  
PHARMACOLOGY AND THERAPEUTICS?

## B. THE VIEWPOINT OF THE PHARMACIST.\*

DR. BERNARD FANTUS, PROFESSOR OF PHARMACOLOGY AND THERAPEUTICS, COLLEGE  
OF MEDICINE, UNIVERSITY OF ILLINOIS, CHICAGO.

The honor having been conferred upon me to participate in this symposium by presenting the viewpoint of the pharmacist, I proceeded to obtain this information by sending out *questionnaires* to leading pharmacists all over this country, with the request that these blanks be distributed among pharmacists known to be competent to make the desired examination of one hundred prescriptions each. In this manner, I believe, we have obtained reliable information from a considerable number of high-grade pharmacists representing the various sections of this country and all varieties of prescription practice. As might have been foreseen, I obtained quite a variety of reports, which, however, when averaged up in groups of ten, gave strikingly similar results.

Before presenting the report, it might be well to ask ourselves the question, What does the pharmacist know about the kind of instruction that ought to be given in pharmacology? The pharmacist merely sees one of the results of our instruction, and, I am willing to admit, not the most important one; for, of course, prescription writing is not the end and aim of our course. Still, I believe it will be granted that prescription-writing is a good index of the thoroughness of the training given, since it not merely requires an acquaintance with the rules for writing a prescription, as well as with pharmacodynamics and with therapeutics, but also a knowledge of pharmacy and of chemistry. Prescription-writing is the keystone to the whole pharmacotherapeutic arch. It is because prescription-writing presupposes a sound knowledge in these various directions, that medical students, in general, consider it a difficult accomplishment; and, I am afraid, there are even some instructors in pharmacology, who feel themselves on thin ice when confronted with the necessity of writing prescriptions or of criticizing those written by their students. No one who is not thoroughly grounded in pharmacology and in materia medica can feel himself at home in prescription-writing. On the other hand, of course, the best pharmacist is incompetent to prescribe for any case of illness because he lacks the necessary knowledge of pathology, of pharmacodynamics, and of therapeutics. However, I believe it will be admitted that a good pharmacist is competent to express an opinion upon the thoroughness with which pharmacy and materia medica are taught in our medical schools. It was with this idea in mind that I sent out, from the pharmacologic department of the University of Illinois, a question-blank, which is given herewith, together with the average percentages yielded by an examination of 10,000 prescriptions by about 100 pharmacists in various sections of this country.

\* Presented at the Second Annual Session of the Federation of State Medical Boards of the United States.

## REPORT ON THE EXAMINATION OF 10,000 CONSECUTIVE PRESCRIPTIONS.

a.	Written in English.....	36
b.	Use of poor Latin.....	18
c.	Almost illegible.....	4
d.	Use of metric system.....	a small percentage
e.	Number of ingredients.....	
	1. Less than three.....	46
	2. More than five.....	11
f.	Proprietarys .....	24
g.	Specified preparations.....	11
h.	Incompatibilities .....	2
i.	Over-doses and errors.....	1
j.	Has the quality of prescription-writing improved or deteriorated within the last ten years?.....	Improvement reported by 55 <i>per cent.</i> . In what respects?.....More U. S. P. and N. F. preparations used. Deterioration reported by 20 <i>per cent.</i> .....
k.	Other remarks.....	"Doctors have an insufficient knowledge of pharmacy and prescription-writing" reported by quite a number.....

The first point shown by this investigation is that over one-third of all prescriptions are written in English; and that almost one-fifth are written in poor Latin. In view of the fact that, no doubt, all medical students are taught to write prescriptions in Latin, it is evidently a rather poor result that less than one-half of the prescriptions written are in correct form. We note from the report that four *per cent.* of the prescriptions are "almost illegible." Of course, there is no excuse for any of them being written so poorly; but, in view of the popular idea regarding the bad chirography of physicians in prescription-writing, and the jokes leveled at the medical profession on account of this, the showing seems to me remarkably good. I am wondering, however, whether four *per cent.* of the checks on banks, written by physicians, would be reported upon as almost illegible.

The metric system is not yet used to any extent in this country. This is unfortunate. The existence of the two systems of weights and measures side by side is surely an abomination. The use of one or the other must be discontinued; and the sooner this is done the better. Now which one shall it be? Science says the metric system is the only one fit to survive; it is chiefly the force of inertia that maintains the other. The medical students in the majority of our schools are embarrassed by being taught prescription-writing in the metric system in their courses in pharmacology, and by finding their clinical teachers in the practice of medicine and in the specialties still using the old system. Would it not be possible for our revered old medical teachers to adopt the new system, even at the expense of some exertion and vexation on their part, in order to spare the host of those entering the profession the difficulty and annoyance of learning both systems, and possibly mastering neither? I believe resolutions are in order among all the faculties of our medical schools, that henceforth only one system of weights and measures shall be used by all the members of the faculty and that this system shall be the metric system. I am wondering whether this great and powerful national body could do something to save our students the necessity of learning the use of two systems of weights and measures.

Poly-pharmacy is defined as the prescribing of too many medicines, especially

in one prescription. Surely more than five is too many. Our report shows that poly-pharmacy is still practiced to the extent of eleven *per cent.* On the other hand, we ought to congratulate ourselves upon the fact that almost one-half of all prescriptions written are comparatively simple in composition, containing less than three ingredients.

We now come to perhaps the most significant portion of the report, namely, the extent to which proprietary medicines are prescribed. While I am not narrow enough to believe that proprietary medicines should never be prescribed, surely twenty-four *per cent.*, the figure shown in the report, is too high to represent a desirable condition. It is somewhat of a disappointment after all that has been said and written against the use of proprietary medicines, to discover that one prescription out of every four still calls for proprietaries. I find that pharmacists, in general, base their reply to the question whether prescription writing has improved or deteriorated, upon their experience in the use of proprietaries. Bearing in mind that most of these reports come from pharmacists, who have been prominent in the so-called "U. S. P. and N. F. Propaganda," and who, probably, have concentrated their propaganda upon the physicians whose prescriptions they receive, the figure in the report is probably too low to represent the condition existing in general. Proprietary medicines, I take it, owe their existence to a combination of factors, none of which is of credit to either medicine or pharmacy. No one will dispute the conclusion that, if pharmacology, using the term in the widest sense, were properly taught, the use of proprietary medicines would reach a very much lower percentage. It is unfortunate, by the way, that no better agreement exists on the meaning of the term pharmacology. The proper definition is the one accepted by the Chairman of this meeting, namely, that it includes the study of *all* that is known about drugs; and not merely the study of the action of drugs upon living forms, as it is defined by some. For this portion of pharmacology the term pharmacodynamics should be used. It is instruction in pharmacology in the narrow sense, instead of in the wider sense, that is responsible for the helplessness on the part of the graduates of some of our best schools, when it comes to prescription-writing.

The use of specified preparations denotes a lack of confidence in the pharmacist on the part of the prescribing physician. I am glad to note that it does not exceed eleven *per cent.*

That incompatibilities do not exceed two *per cent.* is perhaps somewhat gratifying. Though over-doses and errors do not exceed one *per cent.*, that number even is too great, considering the seriousness of the possible issue. It shows the advantage of the services of the pharmacist in safeguarding us and our patients against errors.

On the question whether prescription-writing has improved or deteriorated, my correspondents are divided. About fifty-five *per cent.* report improvement, mostly in respect to the prescribing of fewer proprietary medicines. Twenty *per cent.* report deterioration, and the balance of my correspondents do not commit themselves on this point. Quite a number, however, note, under "other remarks" that doctors have an insufficient knowledge of pharmacy and prescription writing. That this is quite a general opinion on the part of pharmacists may be judged from several papers that have been written on this subject within the

last year. I may mention R. H. Needham's paper on "Do Physicians Understand the Fundamentals of Prescription Writing?" presented before the Nashville meeting of the American Pharmaceutical Association in 1913, in which he arrived at a negative conclusion. I would also like to call your attention to a paper by L. E. Sayre, on "Materia Medica in Medical Colleges," published February, 1914, in the *Journal of the American Pharmaceutical Association*, in which he points out that this teaching is deficient.

After all, however, pharmacists do not see our worst failures in the teaching of prescription-writing. I am convinced that a certain proportion of our graduates, on entering practice and finding themselves incompetent to write prescriptions, solve their problem by not writing prescriptions at all, dispensing their own remedies, with all the evil results of such practice.

Summing up our findings, it becomes evident that there is need for considerable improvement in prescription-writing. This could be secured if it were realized that prescription-writing cannot be taught by lecturing or by demonstrations; that the students must be drilled in prescribing. I believe that the best results can be obtained, if a course on pharmacy and prescription-writing be given before the work in pharmacology is taken up. The students should be made familiar, in this course, with the various classes of pharmaceutic preparations and their prescribing. Then, when the student enters his course in pharmacology he is ready to write prescriptions from the very beginning; and he ought to be required to write prescriptions for each of the important drugs as they are studied, paying special attention to methods of pleasant and efficient administration. When the student finally advances to the study of therapeutics he should be required to write prescriptions from the standpoint of the effect. Finally, if the clinical instructors would do their duty and require the students to write prescriptions for the remedies needed by the patients treated in the hospital and in the dispensary, our students would leave our medical colleges well trained in prescribing.

There are two ways in which state medical examining boards could bring about improvement in prescription-writing. First, by restricting their examinations to the "List of Useful Drugs," published by the American Medical Association, or, if this list does not suit them, to any other list they may choose, and by publishing this list so that teachers in this branch may be able to concentrate their students' energies upon the really useful and important drugs. With the limited time at our command, we can only do one of two things, either give our students a superficial and therefore useless knowledge of a large number of drugs, or, a thorough acquaintance with a relatively small number. Surely the latter would be much the more profitable course; this we would pursue, if the state boards would help us by giving us a list of drugs to which they would confine the examinations. Secondly, by requiring candidates to write actual prescriptions in the examinations. This would serve as a wonderful stimulus to teachers and students alike to perfect themselves in the art.

## THE MONASTIC DISPENSARIES OF THE MIDDLE AGES.

---

LEO R. A. SUPPAN, M. D.

---

According to ancient tradition the systematic practice of medicine and pharmacy reached a high stage of development in Egypt, whence it passed to Greece and from there to Rome. With the extinction of the old Roman empire in the sixth century, came a subversion of the ancient social order in which the physicians shared. The medical practitioners representing the Graeco-Roman school became extinct. But many of their teachings continued to linger among the lower classes, to be ultimately transformed into an unreasoning and grotesque folk-medicine, while the real medical science, such as it was, became the heritage, in Western Europe, of the Monks, who, for nearly four centuries exercised it as their exclusive monopoly.

It was the Benedictines, particularly, who kept alive in the earlier centuries of the middle ages the body of medical and pharmaceutical studies and practice. When St. Benedict of Nursia established his monastery at Monte Cassino in 529, one of his rules was that the monks should devote such time as was not taken up by their religious duties to the collection, study and copying of ancient manuscripts. There is still in existence a letter from the learned Cassiodorus, statesman, writer and monk of the sixth century, addressed to his brethren, in which he recommends them to study diligently the works of Hippocrates, Galen, Dioscorides, Caelius, Arelanus and other Greek and Roman writers on medicine and *materia medica*; and he exhorts them to become acquainted with all useful plants, to familiarize themselves with the compounding of drugs and to inquire into everything that may be of benefit to the sick and afflicted who take refuge in the monasteries. Naturally, all the monks were not of equal learning; there were some who understood Greek, and these made translations into Latin, compiled lexicons and wrote commentaries; Cassiodorus recommends those who are not familiar with the Greek language, to read the works written in that tongue in translation. Those brothers who had no great aptitude for learning were employed in other useful occupations, many of them finding a place in the *scriptoria*, or writing-apartments, where they busied themselves with the copying and illumination of manuscripts, many of which have come down to us, and are, to-day, highly prized objects in the great libraries and museums of Europe. It is to the rapid and extensive multiplication of the Benedictine monasteries, subsequent to the founding of the parent house at Monte Cassino, that we owe our possession of many of the most precious works which were the fruit of Greek and Roman genius; for every monastery, large and small, was a busy work-shop, where the transcriber was at work in his quiet occupation.

The monasteries in their first inception were places to which the pious might retire from the vanities of the world and devote themselves to religious contemplation and the prescribed ceremonies of the Christian church; but they soon added another important function, that of extending hospitality to travelers, both of high and low degree. Every one had its guest house, where refuge with accompanying entertainment was furnished. No charge was made, but the guests were

expected to present some token of appreciation according to their means, upon taking leave. Rooms which were set apart for the care of sick monks also received the poor of the neighborhood, who were attended by the physicians in charge of the conventual infirmaries and dispensaries. Moreover, in the absence of medical schools outside the convent walls, the monastic physicians were called to attend exalted personages at their own residences, often many miles away, upon which professional expeditions they were usually accompanied by assistants who were pupils and who prepared the required medicines under the direct supervision of the doctors. In some cases the physician, when called to a distant patient, carried with him the remedies already prepared. An instance of this kind is related in the *Chronicon Monasterii Cassinensis*, as follows: In the eleventh century, there lived in Monte Cassino, a monk named Alfano, who was distinguished for his scientific mind, and his attainments in the healing art. On one occasion the Abbot, Desiderius, paid a visit to the pope, and being ill, he took Alfano with him in the capacity both of friend and medical attendant. Alfano took with him a number of medicaments, which he had prepared beforehand, an indication that there existed in the monastery, a laboratory of some kind, in which they were made. One of the inmates of Monte Cassino, at that time, was Constantinus Africanus, whose name is indissolubly linked with the famous medical school of Salerno, the first secular institution of its kind in western Europe.

Berendes, in his work, entitled, "Das Apothekenwesen," states that Dr. Albers, the keeper of the Archives at Monte Cassino, expressed to him the opinion that Constantinus was the first to arrange the monastic dispensaries according to a definite plan.

In a monograph entitled, "Wilhelm der Selige, Abt von Hirschau" (William was elected Abbot in 1071), Kerker confirms the surmise that the early monasteries contained a pharmaceutical laboratory and dispensing department of some kind. He shows that in the Benedictine house of Hirschau, situated in the Black Forest, there existed an infirmary or hospital over which presided an *infirmarius* or *armarius*, who was always a priest, and who had at his disposal as many assistants as he required to discharge his duties properly. In the infirmary the sick were bedded on rush mats, kept scrupulously clean. In the middle of the monastery was a covered space with an opening in the center, where blood letting was performed and the sick had their diseased limbs washed and anointed. It was also used as a sort of laboratory for preparing medicines. Every day the *infirmarius* made requisition for the various articles which he required for the sick in his care. But he kept on hand in his *armarium*, which we may translate "medicine chest," certain herbs, spices and other drugs; cinnamon, pepper and ginger are specifically named, which were to be held ready for cases of emergency. Another of his duties was to make the nightly round of the hospital and to see that the drinking-cups of the patients were filled, so that they should not suffer thirst. It is evident from this account that the office of chief infirmarian was an important one, and combined the functions of head physician and head pharmacist.

The title *apotecarius* (apothecary) appears to have been used at a very early date as equivalent to *armarius*, i. e., Keeper of the medicine chest. In his work, "La Pharmacie en Poitou," M. Pierre Rambaud, states that he found the name "apotecarius" in a number of Poiteven title deeds dating from the end of the tenth

century; at the bottom of a deed, drawn in 967, occurs the signature of a certain Salomon, a monk, who appends to his name the word "apotecarius." In 976, the signature of the same Salomon is again found, and this time he calls himself *subdecanus*, or vice dean. In a document of the year 985 occurs the signature of a "Rotbertus, apotecarius," which follows immediately after that of the Count of Poitou, the Abbot, the treasurer and the dean, and precedes thirty other signatures. M. Rambaud cites other cases, all showing that these physician-pharmacists held high stations in the monastic houses, and were men of learning and great administrative ability.

As there were no lay medical schools in the early times of which we are writing, the medical education of the monks who intended to devote themselves to the practice of it, must have been imparted within the monasteries themselves. It was undoubtedly wholly of an empirical nature. The pupil, one may suppose, accompanied his master to the bedside of the patient where he listened to a description of the symptoms and heard the diagnosis, all of which he committed to his tablets for later study; he probably also assisted in the preparation and application of bandages and, under the watchful eye of the master, compounded the necessary medicines. In this way he became acquainted with therapeutics and stored his memory with a vast number of recipes. But he also acquired an excellent first-hand knowledge of the character, properties, uses, and perhaps, cultivation of a number of medicinal drugs, for the monasteries possessed, as we shall see later, medicinal gardens, in which the plants which furnished the bulk of the medicines used in the infirmaries were cultivated. The pupil gained his theoretical knowledge from the works of the Greek and Roman physicians, which he was required to read diligently and, unquestionably, he had to learn by heart the prayer which invariably accompanied the administration of a medicine. Pathology, of course, was a non-existent science in those times.

Every monastery possessed its own formulary or collection of recipes for medicaments of various sorts, and it is astonishing how vast a number of these have come down to later ages. They were copied more or less literally from the ancient writers and were accompanied by prayers, or rubrics where prayers were to be said, while the medicine was supposed to be taking effect. I conjecture, that many of these recipes were embodied in the popular "household medicine books," which were so popular in the seventeenth and eighteenth centuries, and some of which survive at the present day in out-of-the-way corners of Europe.

Toward the end of the twelfth century the monastic medical schools began to lose considerable of their importance, in consequence of the establishment of the medical faculties in the great universities of Paris and Montpellier, to which students streamed from all over Europe. The faculty in medicine at Paris, was probably established before 1160, and at Montpellier instruction in medicine was begun in 1181.

A curious document has come down to us from the ninth century which gives an idea of the arrangement of the medical department in the mediæval monasteries, and which may be fittingly described here.

In the northeastern part of Switzerland there lies only a few miles from the Lake of Constance, the town of St. Gallen, or St. Gall, the chief town of the canton of the same name. It is a thriving place with some forty thousand in-

habitants, and is important for its textile industry. The tourist who is possessed of an historical imagination, and who visits Switzerland more with the purpose of evoking the romantic past, rather than to study modern social and commercial conditions, finds it worth while to stop here for a few days and examine what remains of the old abbey, a monastery founded in 720 by St. Othmar, on the rules laid down by St. Benedict.

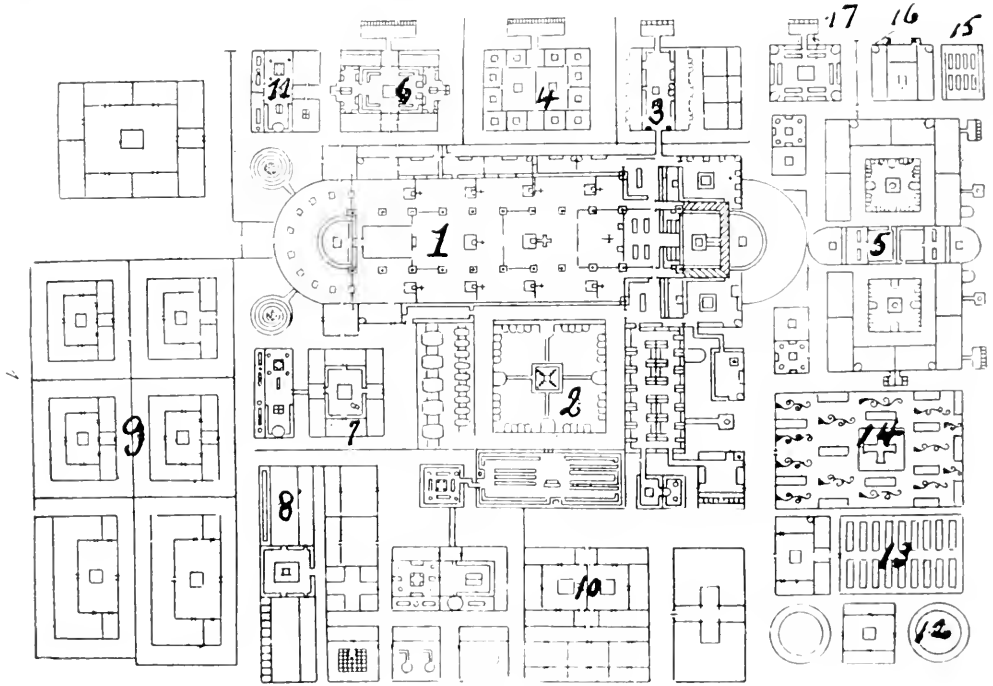

FIG. 1.

General plan of the Monastery of St. Gall in Switzerland, from a copy drawn from the original and published in Brockhaus' Bieder-Atlas.

1. The Monastery church.
2. Cloisters for the monks.
3. Abbot's residence.
4. School for children of the laity.
5. Chapel for the novices.
6. House for the reception of guests of the higher classes.
7. House for the reception of poor pilgrims.
8. Buildings where corn was ground and provisions stored.
9. Stables for domestic animals and living apartments of lay servants.
10. Living apartments for laborers of various kinds.
11. Monastic kitchen, bakery, and brewery.
12. Poultry yard.
13. Kitchen garden.
15. Medicinal garden.
16. Dispensary and pharmaceutical laboratory.
17. Bleeding-house.

In the year 613, or thereabout, a pious recluse named Gallus or St. Gall, a follower of St. Columba, left Ireland on the destruction of the famous Irish abbey of Bangor by the Danes, and established his hermit's cell in a dense forest, which reached from the Lake of Constance to the Santis Mountains. Here he devoted himself to missionary work for the conversion of the half barbarous tribe of the Alemanni, in which he was so successful, that in the course of but a few years, huts and other little buildings sprang up on the site of his labors. These rude settlements formed the nucleus of the great monastery and the town bearing the Saint's name, which grew up and flourished under its walls. The abbey became

very wealthy through the gifts of pious well-wishers and, down to the end of the eleventh century, was the site where literature and the sciences, such as they were in the middle ages, were assiduously cultivated and flourished under the liberal patronage of learned abbots and other benefactors of the convent.

To the student of pharmaceutical and medical history, the abbey of St. Gall is of particular interest, from the circumstance that in the year 830 the abbot Gozbert conceived the idea of reconstructing the monastery buildings and entrusted the devising of a suitable plan to Eginhard, it is said, the architect of Charles the Great. This plan not only gives us a clear idea of the arrangement of monastic settlements as they were deemed suitable in the earlier period of the middle ages, but it also shows us the provisions made for the care of the sick, and the source

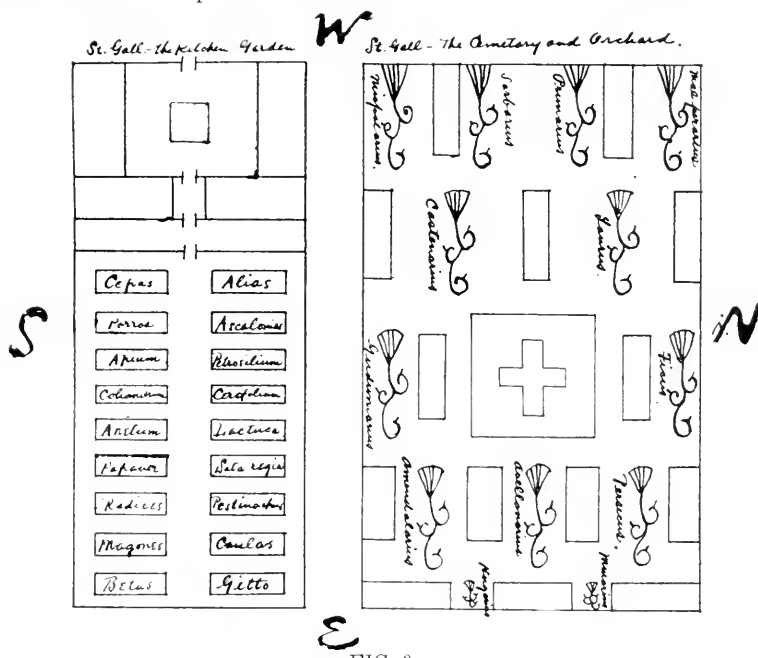

FIG. 2.

The kitchen garden and cemetery at St. Gall, after a sketch by J. Berendes, published in the *Pharmazeutische Post*. The kitchen garden is to the left in the plan and the cemetery with orchard to the right. The meaning of the terms used in this plan is explained in the text.

and preparation of medicines for the relief of their affliction. There is some doubt as to whether the abbey was really reconstructed according to this plan, for, in the Napoleonic era, the foundation became much enlarged and many of the buildings then existing were modified, some being turned over to the government for the accommodation of public offices and others transformed into dwelling houses. The original plan is still in existence and consists of a sheet of parchment, sewed together of four skins, the whole about three and one-half feet long and two and one-half feet wide, the lines being drawn in red ink. It was published in *fac-simile* by Ferdinand Keller at Zürich in 1844, with explanatory notes, and by Professor Willis, in England in 1848.

The plan shows a complex of buildings about four hundred and thirty feet in

The identity of the plants indicated in the plan of the kitchen-garden are in some instances open to conjecture. A. Tschirch, in his *Handbuch der Pharmacognosie* gives the following modern equivalents for them:

Cepas— <i>Allium cepa</i> .	Alias— <i>Allium sativum</i> .
Porros— <i>Allium porrum</i> .	Ascalonias— <i>Allium ascalonicum</i> .
Apium— <i>Apium graveolens</i> .	Petrosilium— <i>Petroselinum sativum</i> .
Coliandrum— <i>Coriandrum sativum</i> .	Cerefolium— <i>Scandix cerefolium</i> .
Anetum— <i>Anethum graveolens</i> .	Lactuca— <i>Lactuca sativa</i> .
Papaver— <i>Papaver somniferum</i> .	Lata regia— <i>Satureia hortensis</i> .
Radices— <i>Raphanus sativus</i> .	Pestinachus— <i>Pastinaca sativa</i> .
Magones— <i>Daucus carota</i> .	Caulas— <i>Brassica oleracea</i> .
Betas— <i>Beta vulgaris</i> .	Gitto— <i>Nigella sativa</i> .

To the north of the kitchen-garden, the right of the plan in figure 2, is an enclosure which served both as a cemetery and orchard. In the middle is a huge cross upon which the architect designed the following inscription to be placed:

Inter ligna soli haec sanctissima crux est,

In qua perpetuae poma salutis olent.

(Among the trees of the earth the cross, on which the fruits of perpetual salvation shed their perfume, is the most sacred.)

Hanc circum jaceant defuncta cadavera fratrum

Qui radiante iterum regna poli accipiant.

(Around this [i. e., this cross] shall lie the bodies of the brothers, by whose glory they will gain the realm of heaven.)

The arabesques in this plan represent thirteen species of nut and fruit trees. The names of these with their equivalents are:

Mal perarius—pear tree.	Ficus—fig.
Prunarius—plum.	Gudunarius—quince.
Sorbarius—checkerberry tree ( <i>sorbus domestica</i> .)	Persicus—peach.
Mispolarius—medlar.	Avellanarius—hazel nut.
Laurus—laurel.	Amendalarius—almond.
Castenarius—chestnut.	Murarius—mulberry.
	Nugarius—walnut.

It is probable that the planting of these trees in the cemetery served a two-fold purpose:—they were decorative and at the same time useful.

North of the cemetery is a group of buildings arranged in quadrangular form about a double chapel. The southern half of this group contained a school for the education of the novices, that is, those who were preparing themselves for the monastic life, and a part of the chapel is also set aside for them. The plan (Fig 3) shows the dormitories, refectories, study rooms, (*pisalis*), and bath-house and kitchen.

On the other side of the chapel is a quadrangle inside of which is a large square building marked *Fratrum infirmarium*, or infirmary for the monks. (The infirmary, it may be remarked *en passant*, was not only a hospital in the modern sense of the word, but also served as a refuge for monks whose age or other infirmities incapacitated them from taking part in the devotional exercises and other occupations of the monastery.) In the block around the infirmary are a refectory, a living room, study room, dormitory (*domus magistrorum*) and a chamber marked *Domus Valide Infirmorum*, or house of those dangerously ill.

But the row of rectangles to the north of the large block of buildings just described is what interests us most. (Numbers 15, 16 and 17 in figure 1.) There are three of them, two being grouped together in the extreme north-east corner

maladies were of such a nature as to require the immediate attention of the physician at any moment, since it is connected directly with the physicians' quarters. The room marked "Armarium pigmentorum" is the apothecary shop or dispensary. It was here that drugs were stored and compounded on the order of the chief physician by his assistants. Unfortunately we have no information as to the arrangement of this dispensary, but it is probable that according to modern ideas, the apparatus used was extremely crude, being confined to the pounding-mortar and infusion pots.

Adjacent to the Doctors' house is the medicinal garden, divided into sixteen plots. Here were grown the medicinal plants which constituted the vegetable materia medica of the monastery.

The names of the plants are indicated in the plan, and nearly all these have been identified with plants known to us. This medico-botanical garden deserves a paper for itself, and so only a brief notice can be given here, to the plants cultivated therein. The following table gives their names with the modern equivalents:

Lilium—*Lilium candidum*.

Rosas—*Rosa rubiginosa*, sweet briar.

Fasiolo—*Dolichos melanophthalmos*, says Berendes.

The commentators are at variance as to the nature of this plant. The Greeks called a certain kind of bean which was cultivated in their gardens *Phaseolus*. I have not been able to find *Dolichos-Melanophthalmos* in the books at my disposal. It was probably the common kidney-bean which, according to Dioscorides, was esteemed as a diuretic in ancient times.

Sata regia—*Satureia hortensis* summer savory.

Costo—*Tanacetum balsamita*.

Fena greca—*Foenugreek*.

Rosmarino—*Rosemary*.

Menta—Probably *Mentha Crispa*, aquatica and *piperita*.

Salvia—*Salvia officinalis*, sage.

Ruta—*Ruta graveolens*, rue.

Gladiola—*Iris florentina* and *germanica*.

Pulegium—*Mentha pulegium*, pennyroyal.

Sisimbria—*Mentha crispa*.

Cumino—*Cuminum cyminum* cummin.

Lubestico—*Lecristicum*, lovage.

Feniculum—*Fennel*.

The plan of St. Gall represents an ideal Benedictine monastery as it was conceived in the mind of the architect, but it is not certain that it was ever realized in its entirety, and so the medicinal garden just described may not be the one that actually existed. But we have an interesting document of the same period in which are described the medicinal plants that grew within this monastery. This is a little book entitled, "Herbularius," or the "Little Garden," and was written by a monk named Walafriid Strabus or Strabo. Strabus was born in 806 or 807, and received his education in the monastic school at Fulda, under the learned abbot Hrabanus Maurus. He was not only keenly interested in the phenomena of nature, but also possessed considerable poetic talent, and in his fifteenth year distinguished himself by some eulogistic verses addressed to Ebbo, Bishop of Rheims. At the age of twenty-eight he entered St. Gall, where his sincere piety and distinguished talents led to his election as dean of the monastery. In 842 he became abbot of Reichenau on the Untersee. He died July 16, 849. More than twenty works are ascribed to him, all written in Latin, of which the one of the greatest importance to the antiquary is a little book entitled, "Hortulus Monasterii Sancti Gallensis, Abbati Grimaldo Inscriptus" ("The Little Garden of the Monastery of

St. Gall, dedicated to Abbot Grimaldus.") The history of this work is somewhat peculiar. It was first given an extended publicity in a poem entitled "De Viribus Herbarum," and bearing the name of Macer Floridus as author, dating from the tenth century. It then fell into utter oblivion for a time, to be rediscovered in the sixteenth century. It was published in Vienna in 1510 under the editorship of J. Watter, a professor at the University there. This edition, which is now very rare, is regarded as the best.

In 1512, Watter's edition was reprinted at Nuerenberg in a more ornate form. We are told that the type used was Gothic and that the title page was decorated with the picture of a garden,—probably an idealization based upon Strabus' description. A certain Johannes Atrocianus or Acronius, professor of mathematics at the University of Basel, gave out an edition which was published in that town in 1527. There is also a Frankfurt edition which bears no date. Of modern editions, may be mentioned that of L. Choulant, which appeared in Leipzig in 1832, and of Reuss, Wuerzburg, 1834. In 1908, Professor J. Berendes published Reuss's text, with a translation in German, in the *Pharmazcutische Post*. The "Hortulus" is a poem consisting of four hundred and forty-four hexameter lines in which are described twenty-three plants cultivated for medicinal purposes in his time. The plants are described and their uses indicated. Not only this, but instructions are given for preparing the soil, sowing the seed and setting out young plants. The descriptions show a keen observation on the part of the author, and their conciseness reminds us that of prevailing in modern pharmacopœias.

The mediæval materia medica offers an interesting subject for study. It is not always easy to trace the plants which were grown in the convent gardens for the monks often applied fanciful names to them, based upon some real or imagined connection with the events recorded in sacred history. Thus we find, "Oculus Christi" for *Myosotis Scorpioides*; "Rosa Sanctae Mariæ" for *Paeonia officinalis*; "Lancea Christi" for *Ophioglossum vulgatum*; "Radix Sancti Spiritus" for angelica root,—many of which are still given as synonyms for popular medicinal plants in European herbals of to-day.

Certain religious orders gained renown for certain special plants to the cultivation of which they devoted much care. The Carthusian gardens at Freiburg in the Breisgau, produced angelica of a fine quality. Licorice root from the Benedictine herb garden at Wurtzburg was highly prized. At a later period, when the process of distillation had come to be understood, the manufacture of essences and cordials engaged the attention of the monks, the well-known "Benedictine" and "Chartreuse" liqueurs which are still produced in our own day furnishing noted examples. Compound medicines were also prepared and later sold to the public who prized them highly. The best known is perhaps the *Eau des Carmes* or *Eau de Melisse des Carmes*, which was first compounded in the pharmacy of the Barefoot Carmelites in Paris in 1611. This preparation became a valuable monopoly of the monks in the course of the century, for they kept its formula secret and maintained its sale by judicious advertising of a sort. Of course, the apothecaries and manufacturers of secret nostrums were anxious to secure the formula, and innumerable experiments were made to ascertain its nature. Many "just as good" recipes were published, but none of them produced a preparation with the satisfying qualities of the original. Louis the Fourteenth, Fifteenth and Sixteenth

granted patents to the Carmelites on this preparation, each for limited periods. In 1780, however, when a new application for a patent was presented, the Paris School of Pharmacy opposed it; but a compromise was effected according to which the monks were to retain their monopoly in consideration of their paying a sum of about two hundred dollars yearly to the College. When the French Revolutionary government suppressed the monasteries in 1791, and confiscated their property, forty-five Carmelites of the monastery of Vaugirard established a company to continue the manufacture of the "*Eau des Carmes*" as a private commercial enterprise. It was provided that as the forty-five partners successively died, the property should pass into the hands of those who survived. The longest to live was Brother Paradise, who became sole proprietor and died in 1831. To the last the *Eau* was prepared on the premises where the forty-five projectors had started it.

The composition of this cordial was never divulged, but the chemist Baumé worked out a formula for a preparation said to resemble it very closely, which was adopted into the *Codex*. It called for balm (*Melissa officinalis*) freshly gathered and freed from the stems, two pounds; fresh lemon peel, four ounces; coriander seed, eight ounces; nutmeg, cloves, cinnamon, all crushed, of each two ounces; angelica root, dried, one ounce; alcohol, ten pints. The cordial was employed as a stomachic and was evidently an extremely pleasant one to take.

The convent gardens existed until late in the eighteenth century, one at Munich being mentioned in 1750. This fascinating subject tempts one into a wide digression; but it is deserving of a paper to itself and must be left to a future occasion.

After a time the monastic hospitals became decadent, for rank commercialism crept in. Certain monk-physicians became famous and were called from their monasteries to attend princes and other persons of high degree. The recompense they received was generous, and they were attracted to the lives of the laity, whose tastes and habits they adopted. They neglected the poor and devoted themselves to the wealthy for the sake of rich fees. In many cases they abandoned their monasteries altogether. Their example was followed by their subordinates of the cloister who adopted a life of vagabondage, and swarmed over the country selling "cure-alls" at extravagant prices and even dabbling in the teaching of their pretended medical secrets to anybody who would pay for them—and there were many who did. Berendes relates an amusing anecdote of a monk, real or pretended, who appeared at Erfurt in 1227 and advertised himself as a specialist in diseases of the eye. His "cure" consisted in delivering a blessing upon lumps of clay, which he then kneaded into a dough and smeared over the eyelids. He was accompanied by an assistant who wrote certain verses, supposed to be wonder-working, upon slips of parchment, which he sold as a panacea at a handsome profit. This precious pair was soon unmasked as a couple of swindlers and chased out of town. The scandal became so great, that in 1131 the council of Rheims forbade the regular clergy to practice medicine. The edict was reaffirmed by the Lateran council of 1139, and that of Tours in 1163. These prohibitions were launched against the monks in order to put a stop to a habit which had become quite common on the part of some of their number, of their leaving the cloisters, whereby they disgraced their order; but it did not apply to the orders of canons and the secular priests who continued to practice medicine and pharmacy for many years after without interference.

Another circumstance, which later aided in discrediting the monastery pharmacies in the eyes of the secular authorities was the competition into which they entered with the lay apothecaries. The precise date at which these latter first appeared is a matter of uncertainty, but it was probably about the twelfth century, although at that time they must have been under the absolute control of the physicians, who were also laymen. It is certain that in 1140 Roger, King of Sicily and Naples, issued an edict, designed to check the quackery of the itinerant monks, in which it was ordered that anybody who designed to practice medicine should subject himself to a "Judgment" (*judicio*) as to his qualifications. This was probably done on the representations of the physicians. The law promulgated by the Emperor Frederick the Second in 1241 adjusted more definitely the relations between physicians and apothecaries and made the calling of the latter a distinct branch of medicine, *not*, however, as is sometimes stated, an independent profession. The doctors of medicine were prohibited from owning a shop for the dispensing of medicaments, but they had full power to exercise supervision over the shops, to inspect them at fixed times and to examine candidates as to their qualifications. These provisions eventually led to friction between doctors and apothecaries, which has been bequeathed to the respective practitioners of our own times. I need refer only to a proposal made by certain physicians within the past few years, to issue certificates to such pharmacists as might be deemed worthy of the distinction in the eyes of the physicians in question, which certificate should be equivalent to the statement that only those druggists possessing it were qualified to dispense prescriptions.

The quarrel between the apothecaries and religious houses which maintained dispensaries became acute when, soon after their founding in 1534, the Jesuits established pharmacies in their houses, at first for the free distribution of medicines to the worthy poor, in connection with their hospitals. There are many documents in existence, chiefly in the form of letters from the Superiors to the members who acted as nurses, exhorting them to keep the hospitals well supplied with the necessary medicaments, but for use within the hospitals only. These orders were not strictly obeyed, for we read that after a while medicines were furnished gratis to the poor outside the walls and indeed, to anybody that asked for them.

This became a drain upon the finances of the houses, and it was found necessary to make a nominal charge for the articles dispensed. The medicines were sold at a low cost and were moreover, of excellent quality—two circumstances which created a large demand. The regular apothecaries, of course, objected bitterly to this state of affairs, and the Superiors, recognizing the justice of their demands, issued order after order, forbidding all commercial transactions in Jesuit houses as against the spirit and letter of the law according to which religious establishments were to act. But even the authority thus exercised was of little avail, for in a fragment of a manuscript letter dating from the beginning of the eighteenth century, we find it decreed by the Superior that all simples intended for filling prescriptions for *composita*, i. e., mixtures, must be purchased from an apothecary in the town and only in the quantities prescribed by the physicians—from which we are led to infer that patients sought the advice of the lay doctors, and took their prescriptions to the monasteries to be filled. Thus a means was

found for avoiding trespass upon the privilege of the apothecaries, and at the same time, preserving the existence of the monastery pharmacies. The latter, however, were doomed to destruction. The apothecaries appealed to the civil authorities to free them from this unfair competition. In 1776 the Elector Max Joseph of Bavaria issued a mandate prohibiting the dispensing of medicines in religious houses within certain limits. He states that complaint was made that the apothecaries were unable to maintain their shops in a state fit for the public good on account of the practice followed in monasteries and convents of selling medicines to the public without discrimination. The medicaments, he says, were prepared and dispensed by monks and nuns who were ignorant of their nature and unqualified to practice the pharmaceutical art; and he, therefore, ordered that the religious houses should close their shops in towns and within a circuit of two hour's distance where apothecaries carried on their business. Failure to observe this mandate was punished with a fine of one hundred ducats. This drastic edict brought forth a petition from the College of Jesuits at Ingolstadt, where a famous public dispensary had been maintained for many years. They claimed exemption from the ruling on the following grounds:

1. Their pharmacy had been in existence for one hundred years and Doctor Naderhirn, Court and Town Physician of Eichstaedt, had for more than forty years obtained his drugs therefrom, a testimonial to their excellence.

2. The pharmacy was presided over by thoroughly competent persons.

3. The Ingolstadt pharmacy was by no means responsible for the decay of the lay apothecaries; the claim that these suffer from the competition of the religious houses is in fact unsubstantial, for there are two in the town of Ingolstadt, who possess more than one shop and are well to do.

4. Whether or not the carrying on of an open shop by a religious order is in opposition to the rules governing such order is a question which the petitioners do not desire to discuss. They call attention to the fact that the practice is sanctioned in Rome and other countries, and they conclude by asking the Elector to confirm their privileges. What answer was given to this petition we do not know. With the dissolution of the order by Pope Clement the Fourteenth in 1773, the Ingolstadt pharmacy became secularized and passed into private hands. In France the circumstances were similar. As everybody knows the Jesuits were the first to recognize the medicinal value of cinchona bark. It was through them, that it was imported into Europe. Encouraged by their successful trade in this drug, they extended their operations and became importers of exotic drugs in general on a large scale. These they sold at retail through their various establishments, a practice which found imitation in other religious communities. The apothecaries prosecuted them and edicts were issued against the Jesuit drug shops, one of 1707 enjoining all convents from keeping medicaments, except for use in their own hospitals. But it was not until the advent of the French Revolution that the practice was finally stopped, when all conventual establishments were sequestered by the Government.

So the monastic pharmacies arose, flourished, and declined as an independent institution. In those which continued to exist the needs arising with a new order of things, were fully recognized and the practitioners submitted cheerfully to the requirements imposed upon all who would devote themselves to the pharmaceu-

tical art. They pursued the prescribed course of studies, took the state examinations and received their diplomas which put them on an equal footing with their lay colleagues; and the adjustment was a happy one, as is proved by the excellence maintained in the conventual dispensaries in our day, both in Europe and in America.

---

### A LAYMAN'S POINT OF VIEW.\*

---

GOVERNOR W. S. HAMMOND, OF MINNESOTA.

---

It gives me great pleasure to come here this morning at the very beginning of your deliberations to bid you welcome, to greet you, and to express the hope that the work that you do here may be of benefit to the Pharmacists of the State, to the Pharmacists of the United States and to all the people with whom in your various capacities you come in contact. The pharmacist is a great deal more than the apothecary of old or the druggist of even more recent days. There was a time when the apothecary shop, the drug store, was a sort of gather-as-you-please place to gossip over the events of the day and incidentally and between times to compound various medicinal preparations. The work of the apothecary was a particular and technical kind of work and there was so little of it that the compensation was necessarily quite large. But there has come a great change in recent years. The pharmacist is the scientific man as was the apothecary of old. He is the technical compounder, the registered druggist, but he is more of a business man than his predecessors were, and because of that fact the people, those who trade with the pharmacist, have been the gainers. The whole calling itself seems to have taken on another form. I imagine there is not so much compounding to-day as there was a few years ago. Great pharmaceutical establishments do a great deal of the work that the old-time apothecary did. Now, under these changing conditions, it is very, very advisable, it seems to me, that there be frequent meetings for communication of ideas and thoughts relating to the business among the pharmacists of the state. The average pharmacist has become somewhat of a business man; he has always been to some extent a business man, but I am inclined to think that to-day he is more of a business man than professional man, while sometime ago, he was more of the professional man than the business man. Now, is there any danger growing out of this? Is there anything that you ought to think about in connection with this change, if I am correctly advised and my conclusions are warranted by the facts? It would be unfortunate if this old time-honored profession should become merely business. So much of the sentiment, so much of the romance would be taken away that we might feel somewhat sad at the change, but more than mere sentiment, more than mere romance—it would be another development of the dollar idea. I admire the successful business man. We cannot but be astonished at the great efforts of the captains of industry. We like the strong, pushing, virile business men who start with little or nothing, and build up gigantic enterprises, but they are business men. We

\* Address delivered before the Thirty-First Annual Convention of the Minnesota State Pharmaceutical Association, February 9, 1915, St. Paul, Minn.

would not want our lawyers, our doctors, our apothecaries, our clergymen, to be distinguished principally as mere business men. We like to have them remain in the realm of professionalism, and be as great and as useful in professional work as others are in the business field. Now, I trust that with these great houses compounding so many of the things that the apothecaries themselves compounded not many years ago, that we will not have a change in this line of work, and that the apothecary may remain the professional instead of the business man, realizing, of course, the necessity of good judgment and of business skill in the conduct of any business enterprise. There are very important matters connected with pharmacy that are wholly unrelated to the mere question of bookkeeping and income and outgo. We are all interested, and you are particularly interested, in the legislation tending to restrict the use of noxious drugs. Here is a line of endeavor that of course should be absolutely divorced from the business end of the work. Here is a question that appeals to you as professional men and as men who desire to adapt their profession to the best interests of their brothers and sisters, and any attempt, I fear, to connect this kind of legislation with the business end of the pharmacist's occupation and profession would tend to detract from the high professional standard that the apothecary has always had, and that the modern pharmacist should endeavor to maintain. I am not a pharmacist, but a mere observer. I have spoken simply as a layman in a general way. My purpose in coming here was not to deliver a lecture. I could not hope to impart advice to men and women like yourselves who have studied the subject for years, but I may in a way represent the layman who looks upon the pharmacist as the majority of laymen do—who wishes him well and desires to see the time-honored and highly-respected profession maintain all that is good in it, and push on to high and better results. I welcome this body here this morning. I repeat my greeting. I trust that you will accomplish much for yourselves and much for the benefit of your profession throughout the state and country. I thank you.

---

### THE HARRISON ACT.

---

F. H. FREERICKS.

---

All comprehensive narcotic legislation is of comparatively recent origin. The first state in the Union to pass a law governing the sale of cocaine was New York, only twenty-three years ago. This was followed within the next five or six years by similar laws in all of the states. It is with considerable pride that we note all of these laws, as enacted in the various states, to have their origin with, or to have been enacted because of the strong support which they have received from pharmacists.

However, after their enactment, it soon became apparent that the narcotic evil had grown to such proportions that these laws in the different states were insufficient to control it. This was due in part to the inadequacy of the state laws, and in greater part to the fact that state officials were either unwilling, unable, or indifferent with reference to the enforcement of them.

It was about seven or eight years ago, that the matter of a general federal law

governing the distribution of narcotics was advanced for the first time. A few years later Dr. Hamilton Wright, who was at that time connected with the Federal Department of State and a representative of our government at the Hague Opium Conferences, became aware of the enormous amount of narcotics then being used in this country. It is reported that he resolved to secure, in some manner, federal legislation which would control the narcotic evil as it existed in this country, and I want to say to you that the federal law which is before you to-night comes to us primarily through the activity of Dr. Hamilton Wright. He was chiefly instrumental in its introduction in Congress. It then first attracted the greater attention of Pharmaceutical Societies, most of which went on record as favoring such a law. Congressman Foster, of Vermont, introduced the original bill, the underlying purpose of which was the control of narcotics, but however little was done toward securing its enactment, for several years. Then Dr. Wright with persistent effort, using his influence with men of standing and power, induced Congressman Harrison, now Governor of the Philippines, to introduce his bill first known as the Foster Bill, but now known as the "Harrison Act." Both Foster and Harrison had little to do with the drafting of the bill.

It was three years ago, that it became generally known that stronger effort was being made to enact a law of this kind. The American Pharmaceutical Association, then in session at Denver, decided to call a conference of the various National Drug Societies throughout the country for the purpose of coming to some decision in the matter. At the conference so called together there were gathered representatives from the various National Pharmaceutical Societies, including manufacturing chemists, and the National Wholesale Druggists' Association. They considered the bill in all its phases, and soon found that it contained an enormous number of impossibilities, not that it was the intent to cause unnecessary trouble, but because the man who had drafted it lacked the necessary practical experience to know how to make it meet the practical needs. Dr. Wright was persistent to have his draft adopted, and the bill was to be brought before the House on the next day. The National Drug Trade Conference proceeded immediately to formulate its objections and presented them at a meeting of Congressman Harrison's Committee arranged for that purpose. There were present at this meeting representatives of the American Medical Association, the Veterinarian Society, Dental Association, and representatives of various other National bodies connected with medicine and pharmacy. After the objections were presented, it became apparent to the Committee in charge, that the Bill, as it was, could not be, and should not be, enacted into a law. It was the decision of Chairman Harrison of the House Committee that Dr. Hamilton Wright and the Drug Trade Conference should together draft a National Narcotic Law, and that he would then see to its enactment. On the same evening and extending through the following days, the conference of the National Drug Trades met with Dr. Hamilton Wright, without coming to an agreement, and this resulted in many subsequent meetings. It should be mentioned that the National Drug Trade Conference at its organization decided that delegates representing all the National Societies interested in this law should be invited to attend its future meetings. I wish to say that in all the sessions that took place for two years thereafter, there were invariably present, representatives of the American Medical Association, who took part in the discus-

sion. I am free to say that, in my judgment, the representatives of the American Medical Association either directly or indirectly have been more largely instrumental in having this law passed as it is to-day than any one set of men constituting the Conference. The representatives of the American Medical Association most prominent in the discussion were Dr. Woodward, of Washington, and Mr. M. I. Wilbert.

Now, I do not mean to go beyond what I have said in speaking of the law and how it was secured, other than to say that Federal Narcotic legislation is, I believe, an essential thing, to supplement State Laws, in view of the fact that the narcotic evil has grown by leaps and bounds until to-day there is not a week passes but that at least 100 arrests for the violation of state laws, as they now stand, are made. It must be plain that, where there are regularly on the average 100 arrests weekly for the violation of a given law, there are many, many more times that many violations.

I have been presented to you as a member of the National Drug Trade Conference. I refer to that fact, because in what I am likely to say, I do not want to be misunderstood. I did have the honor of representing the National Association of Retail Druggists in the Drug Trade Conference, but I wish to say that the form of bill which has now become a law found the more or less willing approval of 14 members of said Conference,—two subsequently dissenting,—and did not find and has not yet found the approval of one member of that Conference, and that member is myself. I tell you this so that I may not be misunderstood. I am not prepared to defend in every respect the form of the law as it now stands, nor am I prepared to defend all the regulations that have been drafted under the law. But it seems to me that the question is, not whether we like the law or whether we like the regulations which have been drafted under the law, but *that we have the law, and we want to know what it is and how it applies to us*. While I am not prepared to defend every provision of the law, yet its aim I am prepared at all times to defend.

The law we are discussing this evening is known and will be known as an Act of Congress approved the 17th day of December, 1914. It will also be known as the Federal Narcotic Revenue Act. Its regulatory provisions are an incident to the taxing powers. The law contains twelve sections, the three last of which concern the government and its officials. To my mind, it seems, first of all, that the ninth section is the most important. It provides that any person who violates the Act is subject to a fine of not more than \$2000.00, or to imprisonment of not more than five years, or both. This alone seems sufficiently important to awaken all of us to the necessity of complying with the provisions of the law.

In Section 1, the law provides that "Every person, partnership, association, company or corporation who produces, imports, manufactures, compounds, deals in, distributes, sells or gives away opium or coca leaves, or any compound, manufacture, salt, derivative or preparation thereof, and not specifically exempt, must, on or before the first day of March, 1915, register with the Collector of Internal Revenue of the district" and pay the special tax imposed for the period, March 1, 1915, to June 30, 1915, amounting to thirty-four cents. That means that every person who is in possession of these drugs with a view of supplying others, no matter in what form or under what circumstances, must be registered under this act. I

should here say that Section 6, by inference, provides that there should be included in the list of drugs specially named under Section 1, alpha and beta eucaine, or any synthetic substitute for cocaine. The field of synthetic substitutes for cocaine and eucaine, including novocaine and alypin, should be constantly in mind.

From now on, for the sake of brevity, I shall use the term "Doctor" to refer in a general way, not to doctors alone, but to dentists and veterinary surgeons, unless for some reason, it becomes necessary to specifically refer to one of them. I understand that the local Collector of Internal Revenue has distributed the Blanks for Registration among the doctors, but unless you have had such application, it is necessary for you to either go or write to the Collector of Internal Revenue for your District, and have him send you an application to register under the Federal Narcotic Act, and to have the necessary revenue stamp. I would suggest that you write for a requisition form upon which you will have to secure the so-called official order forms, which are also furnished by the Internal Revenue Collector. After receiving your application form, go to the Internal Revenue Office, or to a notary, to be sworn, then send it in together with the specified tax. If you see fit to make requisition for order forms, send an additional ten cents. The order forms are done up in tablets of ten forms each. Your remittance will need to be made in U. S. Money Order, cash, or certified check. Forty-four cents covers the tax until July 1, 1915, and ten duplicate order forms. After that date an assessment of \$1.00 is made for the ensuing year, and ten cents for each ten order forms in duplicate.

Doctors must register but once, and that from their office. Druggists, however, are required to register from each separate place of business that they may conduct, and, under a ruling of the Commissioner, which I have, they are required not only to register for the purpose of dispensing on physician's prescriptions, but they are also required to register for the manufacture and sale of narcotics. In other words, a druggist must register under two separate provisions. Certain classes have been provided for, one for Doctors, Dentists, and Veterinarians. In another class belong the manufacturer and the wholesaler, and in still another class, the pharmacist who would sell only on prescriptions. The Druggist under above-mentioned ruling, which may be changed, will need to secure registration both for selling and manufacturing, and again for the purpose of selling at retail on prescriptions, so that each retail druggist, if he has but one store, will have to register twice. The doctor, druggist or dentist who may have an office and a separate residence should register from the office only, but if his office is not separate from his residence, it is, of course, necessary to register from his residence.

The law in Section 1 provides that employees who act within the scope of their employment, and are employees of registered doctors or druggists, do not need to be registered. That is important, because under Section 8 of the law, it is made unlawful for any person other than those who are registered to be in possession of any of the drugs, except in cases of certain exemptions, which will be later referred to.

Under Section 1, the law does not apply to County, State, or Municipal Hospitals, or Penal Institutions, and it does not apply to the Doctor who is engaged

therein, when so engaged. In other words, such county and municipal hospitals are not required to register under the act, and they may purchase the drugs and no record need be kept of the supply to such institutions. The Doctor who visits such *public institutions* is not required to make record of any of the drugs he may order therein, but in private hospitals, the Doctor is required to give to the person dispensing the drug, some authority for doing so. The best way to order narcotics in private hospitals would be to write prescriptions, and for the druggist at such hospitals to fill only under prescription. That applies to private institutions, and in private hospitals, it is always necessary, for the Doctor to make a written order *not to be kept by him*, but to provide a record to be kept by the person who supplies the drug in the house.

With reference to veterinarians, many, I believe, conduct hospitals of their own, and whenever this is the case, they are, under the regulations of the department, required to make a record of all the drugs they would dispense and use in their hospitals.

Under Section 8, possession of the drugs by unregistered persons becomes absolutely unlawful, except in cases of specified exemption, and when these drugs are found in the possession of any unregistered person, it is for that person to prove that he is in lawful possession of them. Possession is lawful when in the hands of a person acting within the scope of his employment. Possession for a registered person is lawful when found in the hands of nurses to whom they have been given by the Doctor, when they are used under the supervision of the Doctor, and only in such cases is possession of narcotics by nurses lawful unless they are registered. They must come from the doctor to the nurse for use in administering to the patient of that doctor, and in no other way.

Possession is lawful for those who have it because of a doctor's prescription, or to whom as a patient it has been given by the doctor.

There is one very important exemption with reference to preparations that contain some of these drugs in minimum quantities, and I would make clear that this includes preparations on physician's prescriptions. This exemption is with reference to preparations that contain, in the fluid or avoirdupois ounce, not more than 2 grains of opium, nor more than a  $\frac{1}{4}$  grain of morphine or its salts, nor more than  $\frac{1}{8}$  grain of heroin, nor more than 1 grain of codein. In other words, an ounce may contain not more than two grains of opium, not more than a quarter of a grain of morphine, or  $\frac{1}{8}$  grain of heroin, and not more than a grain of codein. If it *does* not contain more than these quantities, then the act does not apply in any shape or form. Preparations for external use that are in good faith intended for external use may contain any quantity of opium, or any quantity of the derivatives of opium. Neither the doctor nor the druggist is required to make a record of such distribution. It is a question as to whether suppositories should be regarded as being for external use. I do not believe that the pharmacist would be allowed to sell suppositories unless upon a doctor's prescription. No preparation intended for either external or internal use may contain any cocaine, alpha or beta eucaine, nor any substitute for them, unless it be on doctor's prescription or record.

There is an exception with reference to decocainized coca leaves, or, in other words, the leaves or its preparations from which all cocaine has been removed.

Section 2,—the most important section of the law, in so far as it concerns us all, provides that the sale and distribution of the narcotic drugs may now be made only on an official order form excepting certain exemptions. There can be no sale by the manufacturer or by the jobber to either the doctor or the druggist, unless it be on this official order form, which has been specially drafted by the internal revenue department, and is supplied by the collector of internal revenue. It will contain your registry number and bear your name, and you will retain this number throughout the period of registration and also when you re-register. Each order form, when filled out, must carry the date of the order, also your signature, registry number and address. It must be made in duplicate, and the original is sent to the manufacturer, to the jobber, or to the pharmacist, and must be preserved by them for two years. It must be filed by the person or firm filling that order in its regular numerical order. For instance, all orders from a person registered as No. 95 must be filed together, no matter when they come. The doctor or druggist who places the order, is required to keep his duplicate when order is filled, for two years in a place readily accessible for government officials who are charged with the enforcement of the act.

All sale and distribution of narcotics, as stated, must be upon official order forms, excepting in instances governed by sub-section (a) and (b) of Section 2. The drugs that the doctor, dentist, or veterinarian supplies to his patients upon whom he *personally attends*, need not be recorded on the official order form. Under a regulation which the commissioner has promulgated it is ruled by him that personal attendance *means personal visits*, and the doctor is required to make and keep a record of all the drugs that he would dispense, to his patient, at the office, but he need keep and make *no record when he visits the patient at his home*. In other words, the doctor is not required to make or keep a record when called to attend a patient at the patient's home. He may there dispense all the drugs necessary without being required to make or keep a record. But when the doctor dispenses in his office, he must make a record of that he dispenses. He may select any kind of record-book that suits his fancy, but it must be kept specifically for that purpose, and he must enter therein the name, and address of the patient, and the date, and quantity of the drug dispensed to that patient. This applies also to the administration of hypodermic injections of narcotics in the office, but not at the bedside of the patient. This must be done regardless of the quantity that may be administered. This applies to dentists as well. Every time a dentist uses cocaine or a synthetic substitute in a dental operation, he will have to make a record of it in his office. I have already stated that when the doctor prescribes these drugs in private hospitals, he must provide the means of recording to the person who gives the drugs. The most ready way is to write a prescription to be filed by the pharmacist, or it can be noted on the chart containing the patient's hospital record. Private hospitals are required to show what they have done with narcotics bought on official order forms, and there will be no way to do this unless the doctor gives them some written order.

Now, I have stated that any kind of book that suits you, can be used as a record book, but it must be used exclusively for recording the distribution and the dispensing of these drugs. I would suggest that it be used also to keep therein your

duplicate copy of orders that you may give, and also an inventory to which I will refer later.

After the first day of March, no pharmacist will be permitted to fill your prescriptions for these drugs unless you are registered under this act. The prescription which you write must contain your registry number, your name and address, the name and address of the patient, and finally, of course, the quantities ordered, and the doctor's full signature. Pharmacists may not fill prescriptions wherein these requirements have not been fulfilled, except, of course, with reference to compounds that may be ordered on prescription which contains not more than the minimum quantities allowed.

The question has been raised as to whether a doctor might not, after having written a prescription meeting all the requirements of the law, order such prescription refilled in writing. This is a matter that has not been ruled upon. However, I should think that, if the prescription-blank upon which the doctor would order a re-filling of the first prescription, complies with all the original requirements, then he should be authorized to write "Re-fill prescription, No. —," and the pharmacist should be authorized to refill it. The pharmacist, when he receives a doctor's prescription for any of these drugs must keep it upon a separate file. He may number his prescriptions in their regular order, but those containing these drugs beyond the exempted quantities, must be kept on separate files by the pharmacist. If the pharmacist does not choose to keep them on separate file, he is required to keep a record-book in which he must enter, in each instance, the name, address of the person for whom the prescription is intended, and the name of the doctor. He must use one of two ways. The most practical way, in my judgment, would be to keep two files, to number the prescription in its regular consecutive order, and to keep those containing narcotics on separate file, referring thereto by memorandum on the principal or regular file. Let me say to my friends, the druggists who are here, that if I were still in the drug business, I would find out from my neighboring doctors and dentists what their registry numbers are, as soon as possible, and then have prescription blanks made for them to contain these numbers and addresses. I make that suggestion purely from a practical point of view. Under Section 3 of the Harrison Act, every person who has registered and who buys these drugs and has them in his possession, may be called upon to make a sworn statement as to what drugs he has purchased during three months prior to the time of such demand for a statement. During three months prior to the demand for a statement, you may be asked by the collector to give an account of all such drugs you have purchased, the quantities of the same, from whom and when purchased. You may be called upon at any time by the collector of internal revenue to make a sworn statement to the foregoing effect.

These requirements are made in order to ascertain the violators or those who are likely to be violators. In other words, if the collector of internal revenue finds from the sale of official order forms that any person seems to be using an out-of-proportion number of them, you can look for him to make the demand in that connection. After the first day of March, any person who supplies the consumer with narcotics, must make an inventory of all the drugs in his possession. It must be completed and sworn to by the person, on or before the fifth day of

March, and then must be filed by that person, so that when the inspector calls upon him within two years, he may be able to produce it. My suggestion would be to file this inventory with the record-book, or with the duplicate copies of your official order forms. The inventory must include everything,—the drugs themselves, the preparations that contain the drugs in more than the quantity exempted,—and then be filed by you for inspection of the authorities at any time within the next two years.

With reference to the registry number of the physician's prescription, there is no specific form or requirement. It is only necessary that the prescription shows your registry number, name and address. My suggestion would be that the following words be used:—"Registry No. —, under Drug Revenue Act of Congress, approved December 17, 1914." This may be just at the upper left-hand corner of the prescription. This, it seems to me, would prove in every way satisfactory.

The law also concerns itself, in Section 4, with the drugs that may be carried from one state to another. It is altogether unlawful for any one to carry or to ship narcotic drugs from one state to another, if he be not registered. There are also exceptions to this provision. An employee of a registered person acting within the scope of his employment, may carry them from one state to another, and a Common Carrier may do so. Persons who purchase the drugs upon a written prescription from a doctor, may carry them from one state to another. Persons to whom a doctor has dispensed such drugs, and has made a record of the dispensing, may carry them from one state to another, but in no other case may persons carry these drugs from one state to another.

This brings me about to the end of the Act. I have sought to prepare briefly for you and in just a few words, the important things that apply to the doctor and to the druggist. *First* of all, the doctor and druggist must register. He must secure an application blank, fill it out, swear to it and send it to the collector of internal revenue, and all this must be done before the first day of March. The blanks can be secured and filled out in the office of the Internal Revenue Collector. He must send with his first application for registry thirty-four cents cash, money order, or certified check, and an additional ten cents for ten duplicate copies of the Official order form. *Second*, the doctor should secure a record-book, which he will use exclusively for recording such of the drugs as he may dispense at his office. My suggestion would be that he paste in this book the inventory that he is required to make on March 1st, make affidavit to same, and keep. I would suggest furthermore, that he paste therein all the duplicate copies of orders that he may give when purchasing the drugs. The druggist must on March 1st make and swear to his inventory and sell only on official order form, on doctor's complete prescriptions.

I have tried to set before you the important features of this law. I would add that, to me, it seems that the burden of this Act upon the doctor, the druggist, the dentist and the veterinarian, is more imaginary than real. I would also say that, when enforced, it will not cause the trouble that may be apparent when you first study it. When new, it takes a little time to set machinery in proper motion, but when in proper motion, it is neither difficult nor burdensome. I have said that I am not prepared to defend this law in its every feature, nor the regulations that

have already been made, and I am sure there will be added some changes in these regulations. You must bear in mind that the Commissioner of Internal Revenue, more than likely, never heard of these drugs until a month or so ago. We must be reasonable with him. The law has been enacted because of the need of humanity and because of the need of this country. I ask of you to give it your kindly and whole-hearted support, even though it may seem at first to infringe upon your rights and privileges. Let us consider it an essential thing for the good of this country. Let us accept it in the proper spirit, to the honor and credit of the professions.

---

### SOME THOUGHTS ON AN EFFECTIVE PHARMACY LAW.\*

---

ROBERT L. MORELAND.

---

The object of a pharmacy law is to regulate the practice of pharmacy by protecting the public from ignorant and incompetent persons attempting to practice the art. An act usually begins by creating a Board to enforce its provisions; orders examinations to be held and fixes fees; states the qualifications required of the applicants; provides sometimes for registration of pharmacists from other states; defines drugs and poisons; provides penalties for violations, etc.

Only those who have been charged with the enforcement of such a law as is usually enacted, can realize how difficult it is to carry out its provisions,—advantage is taken of every technicality to defeat its purpose and by none more than by pharmacists themselves. On one occasion, in recent years, the Minnesota Board of Pharmacy failed to get a conviction against an unregistered druggist who sold tincture of iodine. At the trial it was deliberately sworn to by a witness that the only use he knew of for tincture of iodine was the purely technical one of *cleaning cuspidors* and that was what the Iodine was to be used for. On another occasion, after an expenditure of several hundred dollars, the board failed to convict a general store-keeper for selling Strychnine, the defense being that the employee who sold the poison was *forbidden to sell it*, although strychnine was regularly stocked and kept for sale.

Most of our pharmacy laws are very defective. A pharmacy law to be effective, should be carefully worded and should specifically state what may be done and what is forbidden, with the fewest possible exceptions and the least superfluous verbiage. It should clearly define the duties of the Board charged with its enforcement and should make the penalties for violations clear and concise and should prescribe the most effective method of legal procedure that can be defined for its enforcement. Then as to what such a law should embody. If the same principles were applied to pharmacy that are embodied in the laws regulating the practice of medicine, dentistry or veterinary medicine, it would do away with one of the greatest troubles in regulating the practice of pharmacy, viz., that none but an individual or individuals duly licensed should be allowed to own or conduct a pharmacy. I mean that unlicensed individuals, co-partners and stock companies

---

\* Read before Thirty-first Annual Convention, Minnesota State Pharmaceutical Association, St. Paul, February 10, 1915.

have no moral right to engage in pharmacy by merely hiring one or more registered persons to conduct it for them. How long do you suppose a stock company of farmers, mechanics or pharmacists, would be allowed to practice law or open an office or offices as physicians or dentists? Why should not pharmacy be regulated along precisely the same or similar lines as the professions of law, medicine and dentistry?

It may be said in reply that there is a commercial side to pharmacy. So there is, but if the commercial side be the greater or more important, it should be divorced from the scientific or professional side, and those who wish to conduct a drug store and sell all the side lines that are now connected with the drug business, should be allowed to do so, and sell drugs, but they should not be allowed to compound any medicinal preparations or prescriptions. The qualifications for such a person should be not less than three years' practical experience and they should be required to pass a very simple examination covering the identification, nomenclature and physical properties of the various drugs and simple preparations commonly sold in a drug store. The man who can weigh out and wrap up a quantity of powdered rhubarb or gentian from a labeled bottle, the quality of which he is unable to determine, or pump from a can, glycerine, the specific gravity and purity of which he is ignorant and has no means of testing, is in no sense a pharmacist but a mere vendor of drugs.

The public has a right to expect that any person who is a licentiate of pharmacy should be competent to compound prescriptions and medicinal preparations carefully and accurately, and to manufacture pharmaceuticals conforming to official standards. This can only be obtained by raising the standard of requirements for pharmacists. For registration as a pharmacist, the applicant should have the necessary training and experience to enable him to compound prescriptions carefully and accurately, and to make all the U. S. P. and N. F. preparations that can be properly prepared on a small scale. He should be able to test and assay his chemicals and such drugs as are capable of assay, and to apply the necessary tests for the identity and purity of official substances and to conduct volumetric and gravimetric analysis.

A minimum of five years' experience should be required of every candidate before he is eligible for examination as a pharmacist, two years of which might be spent in school of pharmacy and he should have been registered as an assistant for at least two years. For an assistant pharmacist a minimum of three years' experience should be required, two of which might be spent in a school of pharmacy, and the candidate should be registered as an assistant for at least two years before he should be eligible to take the examination for pharmacist. There should also be an apprenticeship system, apprentices to be registered on passing an examination such as is now given by the Minnesota State Board of Pharmacy or else present a high school diploma, when they would be registered as an apprentice, and all experience should count from date of such registration.

The law should contain a provision that the keeping open to the public by an unregistered person of any store, shop or place for the sale of drugs, medicines or poisons, should be considered as *prima facie* evidence of a violation of the law. In this state drug stores are conducted by unregistered owners, often in the same towns with registered proprietors, the former of whom never employ registered

help and refuse to sell to strangers. They go on unmolested because the board cannot get evidence on which to begin a prosecution. This feature was embodied in the draft of the amendment to our pharmacy law passed in the last session of our legislature, but I believe it was opposed by some of the members of this association and probably for that reason was omitted from the bill.

The name of the pharmacist conducting the store should be conspicuously displayed on its front and should be on all labels. Physicians, unless they are registered pharmacists, should not be allowed to compound medicines. A physician without any pharmaceutical training, who attempts to compound a prescription, is as much a fakir as a pharmacist, who pretends to diagnose disease and prescribe therefor. Owing, however, to the enormous political power wielded by the American Medical Association and similar bodies it seems to be impossible to keep physicians strictly to their own profession.

Private hospitals, which are alarmingly on the increase and for which there is no need unless to increase the bank account of their owners and provide a safe place to get their experience, should be under the supervision of the Board of Pharmacy, the same as drug stores, and should have a pharmacist in charge. The same regulation should apply to every public hospital and their stock of drugs should be subject to the same inspection and should be kept up to the same standard as the drugs in pharmacies.

The Board of Pharmacy should be supported as at present by renewal fees. This method of supporting a State Board of Pharmacy is much better than that of receiving state aid, as, in every state, politicians try to influence examining bodies, but more particularly every state-supported body. In some states such boards are entirely political which is much to be deplored.

The difficulties encountered in framing pharmacy laws in the past, have been principally on account of the general opposition that seems to be made by legislatures to everything pertaining to pharmacy, and the want of coöperation among pharmacists. The differences of opinion and petty quarrels in their own ranks, have prevented them from presenting the proper arguments in behalf of their requirements and from maintaining a united front against the vicious legislation which is frequently attempted to be forced upon them. In this respect they are much less a power in the various states than those in many other lines of business, which is not as it should be.

I think, however, and most sincerely hope, that we have turned the corner, and that the pharmacy of the next generation will be a distinct improvement on that of the last and that physicians will expect more of and coöperate more with pharmacists and that there will be fewer nostrums manufactured and prescribed and we will get back to the days of prescribing and dispensing U. S. P. and N. F. preparations, instead of the various fanciful mixtures at exorbitant prices and the humbugs with which the market has been flooded for the past twenty-five years.

If such conditions come about, it will be necessary to have better trained pharmacists than we have to-day and pharmacy laws will have to be made more effective or become dead letters, which would mean a retrograde step of half a century in the practice of pharmacy. If ever there was a time in the history of pharmacy when the public needs protection from unscrupulous, ignorant and incom-

petent persons, it is in this age. The old simples of our fore-fathers have given away to complex preparations, active and poisonous principles, heretofore unknown and now in daily use. The pharmacist of to-day must be a pharmacist, chemist, and analyst combined.

I am aware that these few thoughts will call forth a good deal of criticism. They are deliberately written for that purpose and hostile, as well as favorable criticism, will be welcome, as it is only by criticism of proposed or accepted methods that we can ever hope to arrive at even a partially successful conclusion.

---

## BACTERIAL and VEGETABLE TOXINS.

---

J. STANLEY WHITE, PH. C.

---

In these days when the value of such products as antidiphtheria serum and antitetanus serum are recognized on all sides as being unique in their respective spheres, it is interesting to recall that it was as the result of the study of a product obtained from a purely vegetable source that these biological products assumed a practical form. The substance referred to is ricin, the tox-albuminoid principle found in castor-oil seeds, and a comparison of this and allied substances, both of vegetable and animal origin, with similar products elaborated by bacteria may not be without interest.

It is only comparatively recently that the existence of poisonous proteids or tox-albumins has been recognized. The idea that a proteid can produce dangerous or even fatal symptoms or act in any way except as a food dates only from 1884, but, according to Cushny, most of the animal poisons are now believed to be of proteid nature, and the toxins formed by micro-organisms of disease are almost certainly of the same class.

The most important toxins or toxalbumins of the vegetable kingdom are ricin, abrin, and crotin. The two latter are obtained respectively from the seeds of *Abrus precatorius* (jequirity) and *Croton Tiglium*, but they closely resemble ricin, and it will only be necessary here to refer at any length to this last-named substance.

Ricin is an intensely poisonous phytoalbuminose, which may be obtained from castor-oil seeds after the removal of the oil. It occurs only in the endosperm and embryo, where it is present to the extent of 2.8 to 3 *per cent.*, and may be obtained from fresh decorticated and strongly expressed seed by percolation with a 10 *per cent.* saline solution in which it is soluble. The percolate is filtered and saturated at 20° to 22° C. with magnesium sulphate, and the resulting white precipitate separated from the crystallized salts by dialysis. This preparation is not pure ricin, and probably contains a large proportion of albumins. As thus obtained, ricin is a white, odorless, strongly toxic, ash-yielding powder, insoluble in alcohol, ether, and chloroform.

The chemical nature of ricin appears to be analogous to that usually ascribed at the present time to the bacterial toxins and ferments, and the name toxalbumin, originally suggested by Kohert and Stillmark, who first investigated the substance.

is abandoned. Ricin differs in a marked manner from the bacterial toxins and snake venoms by its relative stability towards the natural fluids and ferments of the alimentary tract. For this reason it appears to be absorbed by the intact alimentary tract, and thus may act as a poison when administered by the mouth. The action of ricin is, however, much less powerful in the stomach than when injected hypodermically. The toxicity of the substance is enormous, and it may certainly be regarded as among the most powerful vegetable poisons when injected directly into the blood.

According to Ehrlich, 1-2000th grain per 2 lbs. body weight is fatal; 1 gm. (15.43 grains) subcutaneously is sufficient to kill one and a-half million guinea-pigs, while the lethal dose for man is supposed to be 0.30 gm. by the mouth or 0.003 gm. subcutaneously. It should, of course, be remembered that these figures do not refer to pure ricin, but to ricin contaminated with more or less albumin. Smaller doses, injected hypodermically, soon produce immunity, antiricin being formed.

As previously stated, the observation of Ehrlich of this protective reaction laid the foundation of serum therapeutics. Before discussing the production of antiricin it may be as well to briefly consider the toxins elaborated by bacteria. When pathogenic bacteria grow and multiply in the body, symptoms of poisoning (toxæmia) are manifested; consequently it was inferred that bacteria either produced poisons during their growth or contained poisons. Subsequent experiments proved that the poisonous effects of a few bacteria which passed out into the surrounding media, and the poisonous effects of the other class, seemed to be due to the actual constituents of the bacterial cells. The former are termed exotoxins or extra-cellular toxins, and the latter endotoxins or intra-cellular toxins. Some bacteria, on the other hand, notably the tubercle bacillus, elaborate both exotoxins and endotoxins. These toxins are substances of a very complex composition, probably allied to the proteins. In some instances they appear to be of the nature of enzymes or ferments, and they are direct products of the bacterial cells.

Among the few bacteria producing extra-cellular toxins or exotoxins the bacillus of diphtheria and the bacillus of tetanus are the most important. They are extremely poisonous; in fact, it has been computed that the toxin elaborated by a virulent culture of the bacillus tetanus is the most potent poison known to science to-day. These exotoxins being excreted by the bacteria, are found in solution in the liquid culture media containing the growing micro-organisms. Serum from an animal immunized by injecting into its body small and increasing doses of these soluble toxins, administered at regular intervals and given over a long period of time, is rich in antitoxin. This antitoxin, when properly prepared and standardized, constitutes the antitoxin of commerce. Diphtheria and tetanus antitoxins are prepared in this manner.

In the case of the bacteria which do not secrete a soluble toxin, the killed bacteria themselves are used for immunization. They constitute what are known as the antimicrobial serums, a familiar example of which is antistreptococcus serum, and should be distinguished from antidiphtheria and antitetanus serums, which are strictly antitoxic in nature.

Antiricin may be produced in exactly the same way as an antitoxin; in fact, an-

iricin might be described as a vegetable antitoxin. Rabbits have been immunized by gradually increasing doses of ricin until they have obtained an immunity of 5,000, or, in other words, have developed so much antiricin in their blood serum that they are not affected by 5,000 times as much ricin as would have killed them had no preliminary treatment been instituted.

The immunity acquired for both ricin and bacterial toxins is entirely different from the tolerance acquired for morphine and other drugs. According to Cushny, the latter is due to the cells of the body becoming accustomed to being constantly bathed in a fluid containing the alkaloid. The same tolerance is acquired by various marine animals, which would be killed if suddenly changed to fresh water, but which are gradually acclimatized if the change is made more gradually by adding increasing proportions of fresh water to the sea water of the aquarium. In the case of ricin and bacterial toxins the immunity is due to formation in the body of a substance which antagonizes the original poison and constitutes what is known as an antitoxin. This antagonistic substance circulates in the blood, and can be withdrawn from the immune animal and injected into a second, which then acquires a certain degree of immunity, although less than that of the first. Just as diphtheria antitoxin and tetanus antitoxin are antagonistic only to their respective toxins, so also antiricin is antagonistic only to ricin and does not protect an animal from any other form of toxin.

Various animal poisons, such as snake venom, spider toxin, and eel serum, have been found to act in a similar manner although, apart from bacterial toxins, snake venom is the only one used for therapeutic purposes. By means of this an antitoxin has been produced which has marked prophylactic properties against snake bites, and is used extensively in countries where poisonous snakes abound. In addition to the vegetable toxins—ricin, abrin, and crotin—toxins have also been obtained from poisonous mushrooms.

While antiricin has no practical therapeutic value, yet it was as the result of the study of this remarkably interesting substance that Ehrlich arrived at a practical method of standardizing the bacterial antitoxins, thus establishing a definite antitoxin unit value for these products.

It is not within the province of this article to discuss the physiological methods employed in standardization or the ingenious side-chain theory which Ehrlich evolved to explain the probable action of the antitoxins in producing immunity. Suffice to say that the discovery of ricin paved the way for some of the most wonderful products used in medicine to-day. It is only necessary to consider the tremendous number of lives which have been saved by the timely use of anti-diphtheria serum, and particularly antitetanus serum in the present campaign, to fully appreciate its importance.

*Pharmaceutical Journal of Great Britain, Feb. 6, 1915.*

"Education is a companion which no misfortune can depress; no crime destroy; no friend alienate; no despotism enslave; at home, a friend; abroad, an introduction; in solitude, a solace; and in society, an ornament—without it, what is man?"

THOMAS F. MAIN.

## PRELIMINARY ANNOUNCEMENT.

### Committee on Transportation of American Pharmaceutical Association.

Your Committee takes pleasure in announcing the following very favorable excursion rates for members who propose to attend the next annual convention to be held in San Francisco, August 9 to 15 inclusive. The rates are so low as to afford an admirable opportunity of seeing at a minimum expense our great Western territory, the grandeur of the Rocky Mountains and the beauties of the Pacific Slope, as well as visiting the Panama-Pacific Exposition, in one of the magnificent buildings of which the meeting of the Association will be held.

The railroad fares quoted are for round trip tickets, good for three months, with stop-over privileges west of Chicago.

Direct routes may be described as all running directly into California without passing through Oregon or Washington. Via Portland includes Northern Pacific R. R. (for Yellowstone National Park), Great Northern R. R. (for Glacier National

Park), Canadian Pacific (for Banff, Lake Louise, Field Glacier, etc.) Tourist sleepers are not available generally east of Chicago, but are attached to through Chicago trains leaving Boston, via Boston & Maine and Wabash route on Mondays, Wednesdays and Fridays. New York passengers via West Shore and Wabash can board these cars at Rotterdam Junction. A special tourist or Pullman sleeper can be reserved for parties of 24 and upwards.

The sleeping car rates named are for continuous service; for stop-overs enroute, an extra charge is made which is partially compensated by using the cars for sleeping purposes and thus saving hotel bills.

With the above settled rates for transportation, members are now in a position to make up parties from their respective cities and arrange for suitable stop-overs at points of interest en-route, suggestions as to which will appear in a later announcement.

THOMAS F. MAIN, Chairman,  
166 Chambers Street, New York.

February 25, 1915.

## Of General Interest

The Journal of the American Medical Association contains in its issue of February 27, an interesting article upon Hall's Antidote for Arsenic, a description of which was published in the February issue of the Journal.

The article is by Dr. Henry G. Barbour, Assistant Professor of Pharmacology at the Yale University of Medicine.

The results of his investigations are summed up in the concluding paragraph of his article as follows:

"The foregoing results indicate the apparent futility of parenteral treatment of corrosive sublimate poisoning by such a good precipitant of mercury as Hall's solution. As an adjunct to stomach washing it will quite possibly be found equal in value to tannic acid, white of eggs, or milk, etc., which are now employed."

<>

Frank G. Ryan, president of Parke, Davis & Co., is recovering from a painful injury to his right foot which was inflicted as he was getting off a street car in Detroit, Saturday evening, February 13. While trying to avoid stepping into a puddle of water beside the car track, as he left the rear platform of the car, Mr. Ryan slipped and fell, with the weight of his body upon his foot. He was taken to Harper's Hospital in Detroit, where it was said that he had broken the bones in his foot in two places. He is now resting comfortably, but it is feared that it will be some time before he has recovered entirely from the fracture.

### DRUGGISTS' SUPPLY CORPORATION.

The first convention of this body was held on Monday, February 15, continuing through the week.

This organization, composed of forty-seven wholesale drug houses, made a display of the output of manufacturers of druggists' sundries at its show-room at 181 William street, which was of much interest.

The officers of the corporation are:—President, Dr. William Jay Schieffelin; First Vice-President, Charles Gibson; Sec-

ond Vice-President, Clayton French; Treasurer, William P. Ritchey; Secretary, Francis E. Holliday; General Manager, William L. Martin. The Executive Committee consists of Messrs. Gibson, Ritchey, Holliday, Albert Plaut, and Dr. Schieffelin.

At the luncheon on Friday, interesting addresses on the activities and purposes of the syndicate were made by the president, Dr. William Jay Schieffelin, of Schieffelin & Co., New York City; L. R. Kauffman, of the Kauffman-Lattimer Co., Columbus, Ohio; S. A. Foot, of Lehn & Fink, New York; E. T. Faxon, of the Faxon & Gallagher Drug Co., Kansas City, Mo.; W. T. Carver, of Farrand, Williams and Clark, Detroit, Mich.; Francis E. Holliday, general representative of the National Wholesale Druggists' Association and William L. Martin, general manager of the syndicate.

### EARLY CLOSING IN AUSTRALIA.

According to the Australia Journal of Pharmacy, early closing in that Dominion is accomplished by governmental regulation, upon the petition of the majority of the shop-keepers, under a recently passed amendment to the Factories and Shops Act. The first regulation in regard to this matter was issued on the sixth day of January last, and is as follows:

*"The Executive Council Chamber Melbourne.*

"Under the powers conferred by the Factories and Shops Acts, His Excellency the Governor of the State of Victoria, by and with the advice of the Executive Council thereof, upon a petition certified by the acting municipal clerk of the municipal district of the Shire of Mildura, as signed by a majority of all shop-keepers (exclusive of hawkers and peddlers) of the particular class or kind to be affected, doth hereby make the following regulation, that is to say:

"All Chemists' shops (being shops of a class or kind mentioned in the Fourth Schedule to the Factories and Shops Act

1912, No. 2386) in the township of Mildura within the municipal district of the Shire of Mildura, shall be closed in each and every week during the whole of each year on the evenings of Sunday, Monday, Tuesday, Wednesday and Thursday from the hour of eight o'clock, on the evening of Friday from the hour of ten o'clock, and on the afternoon of Saturday from the hour of one o'clock, and allowing such shops to re-open on the evening of Saturday in each and every week from the hour of seven o'clock until the hour of eight o'clock.

"And the Honorable Sir Alexander James Peacock, His Majesty's Minister of Labour for the State of Victoria, shall give the necessary directions herein accordingly."

F. W. MABBOTT,

Clerk of the Executive Council.

#### THE EIGHTH ANNUAL MEETING OF THE AMERICAN DRUGGISTS' FIRE INSURANCE COMPANY.

At the eighth annual meeting of The A. D. F. I. Co., held at Cincinnati, February 9-10, the following directors were elected:

Chas. H. Avery, Chicago, Ill., L. G. Heinritz, Holyoke, Mass., James H. Beal, Urbana, Ill., W. S. Elkins, Jr., Atlanta, Ga., Wm. C. Anderson, Brooklyn, N. Y., G. O. Young, Buckhannon, W. Va., A. O. Zwick, Cincinnati, O., Lewis C. Hopp, Cleveland, O., Simon N. Jones, Louisville, Ky., John D. Muir, Grand Rapids, Mich., Walter Rothwell, Hatboro, Pa., Geo. B. Kauffman, Columbus, O., M. S. Kahn, Baltimore, Md., E. B. Heimstreet, Palmyra, Wis., and Frank H. Freericks, Cincinnati, O.

The Board of Directors elected the following officers:

Chas. H. Avery, President; L. G. Heinritz, Vice-President; Frank H. Freericks, Secretary and General Counsel; Geo. B. Kauffman, Treasurer; Executive Committee: Chas. H. Avery, L. G. Heinritz, Walter Rothwell, A. O. Zwick, J. H. Beal, Geo. B. Kauffman and Frank H. Freericks.

The year 1914 was the most successful one in the history of the Company. During the year it wrote \$14,785,282 of insurance at a premium of \$150,827.66. The gross savings in premiums made and retained by its policyholders during the year on the business written amounted to \$50,275.88. The gross savings in premiums which the Company has made for its policyholders since it commenced business amount to \$213,035.64. During the year the company had

160 fire losses amounting to a total of \$41,120.64. The total expenses for the year, inclusive of adjustment expense, amounted to \$48,649.90. The Re-Insurance Reserve or Unearned Premiums of the Company on the business of the year amount to \$65,568.50.

The Board of Directors declared a 9% dividend, payable on March 1, 1915.

On January 1, 1915, the total assets of the Company were \$385,350.99, of which \$343,564.30 was represented by Government, County and Municipal bonds.

The total liabilities of the Company, not including Re-Insurance Reserve, were \$9,528.75. After deducting the Re-Insurance Reserve of \$65,568.50, and the value of furniture of \$716.40, the net surplus of the company as to its policyholders amounts to \$309,537.34.

The Board of Directors ordered that the Company, which is now doing business in 31 states, should during the year enter four or five additional states. It gave serious consideration to a possible further reduction in premium rate to the policyholders, and ordered a complete survey of the Company's business with a view of taking action at the next Annual Meeting. The Company, which now has entered the ninth year of its career, looks forward to a most substantial increase in its business for the year and feels reasonably certain that in its tenth year the annual business of the Company will be in excess of \$20,000,000, at a premium in excess of \$200,000. A saving to its policyholders in one year of over \$50,000 in their premium outlays proves the splendid service rendered to the drug trade of the country by those who organized and capitalized The American Druggists' Fire Insurance Company.

#### NECROLOGY.

##### THOMAS KNOEBEL.

Thomas Knoebel, of East St. Louis, Ill. was born at Belleville, Ill. on August 30, 1859 and died at his home in East St. Louis on January 3, 1915.

Mr. Knoebel received his early education in the public schools of his native city, graduating from the high school in 1876. He then accepted a position with Adolph Finke, of East St. Louis, and entered the St. Louis College of Pharmacy, from which he was graduated in 1880. In 1881, he

bought the store of his employer and later moved his place of business to 209 Collinsville avenue, East St. Louis, where he remained until his demise.

He became a member of the American Pharmaceutical Association in 1892 and took a deep interest in its work. He was one time president of the Illinois Pharmaceutical Association and an earnest worker in the promotion of state pharmaceutical legislation in Illinois. He was particularly active in matters of public education, being president of the local Board of Education. He took a deep interest in the education of the poor and lowly, and through his efforts a consolidation of the various school districts of his city was effected, so that all classes, poor and rich alike, were given the equal educational advantages. He was prominent in civic life, being selected at one time as a candidate for the mayoralty of his city.

Aside from his public and business life, there was another phase of his character that endeared him to all who knew him—his kindness to the poor; and his advice to those in distress, and his even temperament, were the complement of the life of his inner home, that was a model in its best and truest sense.

On March 29, 1883, he was married to Miss Minnie D. Eslaman, who with his son, Percy T., survives him.

As expressed by his intimate friend, Hon. W. J. Perrin, "He belonged to no particular organization and was of no particular creed, but better than all he had the highest religion—that of humanity. The highest hope—that of ultimate perfection. His creed was optimism and his rule was patience and perseverance. As one who knew him for forty years I render every tribute willingly, but I know of no tribute higher or loftier than to say that he was in every sense faithful to his trust."

J. W. E.

Joseph Alexander Velsor, President of the firm of Peck and Velsor, New York City died on February 15 at his home 105 McDougough St., Brooklyn, of oedema of the lungs, at the age of eighty-two years.

Mr. Velsor was a cousin of the celebrated poet Walt Whitman. Funeral services were

held at his residence, on Wednesday, February 17.

Mr. Velsor was a member of the A. Ph. A. and of the National Wholesale Druggist's Association and held membership in several social clubs of Brooklyn and New York.

He was also a life-member of the Y. M. C. A. of Brooklyn and a Free Mason. He leaves behind him to mourn his loss, a wife and two children, Joseph H. Velsor and Mrs. Frederick Smith.

## Letters to the Editor

Editor The Journal of the American Pharmaceutical Association, Columbus, Ohio.

February, 24, 1915.

Dear Sir: It may be of interest to you to know that the Executive Committee of the National Association of Boards of Pharmacy will meet at Washington, D. C., (Hotel Raleigh), March 16-20.

Now, as Bert Taylor of the Chicago Tribune might say, notice of "Committee Meetings" is "Zero," in news. However, I believe the coming meeting has more than the usual significance. Big things are growing out of the work being carried on by the National Association of Boards of Pharmacy. Especially the work covered by the Advisory Examination Committee of the Association. Not the least of these is the tendency for the Schools and Boards to "get together" on the scope and character of courses of studies and examinations.

A joint session of the Boards and the Conference of Pharmaceutical Faculties has been listed on the programs of the respective conventions, each year. It has usually been a "tailender," wholly informal in character, without any definite object or program, and as is usual in such cases, without much result.

Now it is proposed to change all this. At the Detroit Convention last year, committees were appointed by both the Conference of Pharmaceutical Faculties and the Boards. These committees to work jointly and to arrange a definite and vigorous program in order that Boards and Colleges might derive maximum benefits from the meeting. Representatives of these committees will meet jointly with the Executive Committee of the N. A. B. P. at its Washington meeting to arrange for definite work to be taken up by the joint meeting of the Conference of Pharmaceutical Faculties and Boards, to be held during the coming convention at San Francisco, in August. It is proposed to make this meeting something more than a

"tailender." The real "Meat in the Nut" and object of this proposed work is the bringing about a closer relationship between Colleges of Pharmacy and Boards of Pharmacy. Especially with a view of finding out and correcting if possible, the seeming lack in many instances, of proper balance between what is taught and examined on, in the schools; and the scope covered by Boards of Pharmacy examinations.

The Conference of Pharmaceutical Faculties' Committees will be represented at the Washington Conference by Professors, Julius A. Koch of the Pittsburgh College of Pharmacy; Henry Kraemer of the Philadelphia College of Pharmacy; and Henry P. Hynson of the Department of Pharmacy, University of Maryland.

Those representing the Committees for the National Association of Boards of Pharmacy will be Mr. Wm. S. Flint of Massachusetts; W. P. Porterfield of North Dakota; and H. C. Christensen of Illinois.

The members of the Executive Committee of the N. A. B. P. are as follows: L. C. Burton, Chairman, Stroud, Oklahoma; L. C. Lewis, Tuskegee, Alabama; W. P. Porterfield, Fargo, North Dakota; T. A. Miller, (Pres. N. A. B. P.) Richmond, Virginia, Ex-Officio; H. C. Christensen (Secy. N. A. B. P.) Chicago, Illinois, Ex-Officio.

A number of other Association members and educators are expected to be present.

There is at present, a great deal of interest in this movement for closer association between Boards of Pharmacy members and School Faculties. Both bodies are looking forward to this as the next big advance in Pharmaceutical Education and Examination Methods.

Inasmuch as all of us—outside of the immediate officers, depend upon the Journals of Pharmacy for information marking the progress of our profession, any space you can spare to announce these meetings, the objects sought and progress being made, will, I am sure, be greatly appreciated, not only by the officers and members of the respective Associations but also by the profession in general.

Thanking you in advance, I am,

Very truly yours,

H. C. CHRISTENSEN,  
Secretary N. A. B. P.

<>

Editor The Journal of the American Pharmaceutical Association, Columbus, Ohio.

February 24, 1915.

Dear Sir: As Secretary of the National Association of Boards of Pharmacy, I have recently received a number of communications from Boards of Pharmacy members, and others, in different states with reference to the advisability of introducing "bills," in state legislatures fashioned along the lines of the "Harrison Act."

There seems to be an impression in a number of instances, that in order to have this law effective in a state, the state must have a law to correspond.

I am attaching hereto a copy of a letter which I have used—with some slight variations, in making reply to these communications. You are at liberty to use it as you may see fit—as an open letter from me as Secretary of the N. A. B. P., quote from, or as a basis for an article with reference to this matter, or not at all.

It would however seem, since I am receiving enquiries, that it might be of advantage to publish some information along this line.

I am,

Very truly yours,

H. C. CHRISTENSEN,  
Secretary N. A. B. P.

COPY OF LETTER.

February 15, 1915.

Referring to your letter of recent date relative to the advisability of introducing into your legislature, which is now in session, a bill fashioned along the lines of the recently passed Harrison Narcotic Law," I beg to submit to you certain facts and opinions which will, I believe, on consideration, point out the inadvisability of introducing such a bill.

First: In theory, the Harrison Narcotic Law, if I understand it, aims to restrict and control the distribution of certain "habit forming" drugs, in order that they may not be illegitimately used. The enforcement of this law is placed in the hands of the Internal Revenue Department of the Federal Government, which certainly has all the "machinery" for enforcing the law and certainly has the reputation of enforcing the law without fear, favor or relaxation.

Second: This law differs, markedly in its application, from the "Pure Food and Drugs Act," which extended only to Imports and Interstate shipments. The Harrison Narcotic Law extends to every state, city, village, town, cross-roads store, rural route, etc., within the United States and its possessions. The pure food and drugs act, does not apply to the manufacture and sale of food and drug products within the state, and hence the states were left to enact and enforce laws for the control of their "internal" affairs. The Harrison Law, however reaches within the state and applies to all venders in certain drugs, regardless of state, city, village or county lines.

Third: Now, a state law along the lines of the Harrison law would mean paralleling the work all along. It would mean, inspectors, expenses, taxes, etc., for state work already being done by the Federal Government.

Fourth: It would also mean the keeping of double sets of records by druggists—those for the Federal Government and those for the state, with endless confusion and annoyances.

Fifth: When, again, in the matter of punishing infraction of the law, the violator would be doubly liable—to the state and to the Federal Government, and inasmuch as the Federal Authorities would be the most

likely to prosecute first, I doubt very much if one would—especially in the case of a jury trial, get a second conviction on the part of the state. Your law would therefore, in effect, become a dead letter.

As a pharmacist, I am opposed to legislation of any kind that will harass the members of a profession, already burdened with laws and regulations, when said legislation serves no good purpose either for the pharmacist, or the public he serves.

As a board member, for several years, I am convinced that it is the duty of Boards of Pharmacy, to be as alert in protecting the interests of the pharmacists of their respective states, as they would be in protecting the great mass of people of the state in which they serve. I am opposed to the enactment of laws of any kind that become dead-letters on our statute books, either because they are unnecessary, or because they lack the support of public opinion, which is essential to the enforcement of any law.

A state law could, to be sure, be made more stringent than the Federal law, but that would be of doubtful advantage. I believe the Harrison Narcotic Law, properly enforced will control thoroughly and efficiently the distribution of habit forming drugs, and if that is done, the end sought is attained.

I hope the Boards of Pharmacy and others interested in pharmacy legislation in the different states will realize the seriousness of a duplication of this law and lend every effort to prevent such mistakes being made.

Very truly yours,  
H. C. CHRISTENSEN,  
Secretary N. A. B. P.

<>

Chicago, Feb. 21, 1915.

My Dear Sir: I used to wonder why Dr. Whelpley always remarked "thank you" when I sent in my five. I now know. It is my turn now to thank you for the contents of the February issue. Just what a druggist likes to read.

Very truly yours,  
JOHN STUCHLIK.

3859 W. 26th St., Cor. Springfield Ave.,  
Chicago, Ill.

## College and Society

### ILLINOIS PHARMACEUTICAL ASSOCIATION.

Owing to some questions that arose regarding the hotel facilities, the Centralia Commercial Club has withdrawn the invitation extended to the Illinois Pharmaceutical Association to hold its next convention in

Centralia. The vote of the Executive Committee of the Illinois Pharmaceutical Association is now announced. The selection of Centralia as the place of meeting has been reconsidered and by a large majority the Executive Committee has selected Springfield. The annual convention, therefore, will be held at Springfield, June 15 to 17, 1915.

<>

### UNIVERSITY OF ILLINOIS SCHOOL OF PHARMACY.

The classes of the University of Illinois School of Pharmacy have organized and elected officers as follows:

Senior class—President, H. L. Eberly; Vice-President, S. B. Trippett; Secretary, L. A. Gorham; Treasurer, Ralph Hawthorne; Sergeant-at-Arms, H. A. Nelson.

Junior class—President, Ed. Baldwin; Vice-President, Frank Graham; Secretary, D. B. Real; Treasurer, Tom Copeland; Sergeant-at-Arms, Ernest Denson; Historian, Warde Ines.

The Phi, Chi and Alumni Chapters of the Kappa Psi Fraternity gave a dance at the new Fort Dearborn Hotel, Chicago, February 5, 1915. The affair was very much enjoyed by a large number of fraternity members and their ladies including many of the Alumni.

<>

### THE COLLEGE OF PHARMACY OF THE STATE UNIVERSITY OF IOWA.

Prof. R. A. Kuever addressed the Iowa Association of Ice Cream and Butter Makers on the subject of Vanilla at their recent convention at Des Moines. He delivered a similar address before the Nebraska Association at Omaha, Nebraska.

Dean Teeters, chairman of the Athletic Board represented Iowa University at the annual meeting of the governing board of the Iowa state conference of inter-collegiate athletics which was held in Des Moines, January 29.

Professor Jagadis Chander Bose of the University of Calcutta, India, one of the most distinguished plant-physiologists of the world, accepted the invitation of the

University to give an address on his discoveries before the students and faculty on February 9.

Professor Bose has lectured before the Royal Institute of London, at the Universities of Oxford and Cambridge, of Paris, Berlin, and Vienna.

The English Government has conferred upon Dr. Bose the decoration of the Companionships of the Star of India and the Indian Empire and sent him on a scientific mission to Europe just a few months before the outbreak of war.

### COLLEGE OF JERSEY CITY.

#### ENTERTAINMENT AND BALL OF THE JUNIOR FRATERNITY.

The Junior Class of the Department of Pharmacy of the College of Jersey City, this year is not only large in number, but also great in activity. They have even formed a new fraternity, having the mystic letters P. I. D., which means

"PROSPICE IUVENTUS DILIGENTIA"

"LOOK FORWARD O YOUTH WITH DILIGENCE."

The Annual Entertainment and Ball of the Junior Class was held on Friday evening, February 12th (Lincoln's birthday) at Majestic Hall, 125 E. 125th street, New York City. The entertainment was well arranged and included besides many other attractions a one-act play and also an American Indian Tableau.

The ball included the latest dances and over two hundred couples took part in the march, which was led by the Dean, Dr. Joseph Koppel. The following other members of the faculty were also present: Prof. Otto Raubenheimer, Prof. Jacob Gutman, Prof. Joseph Koffler, Prof. Adolph Schnitter, Prof. Felix von Oefele, Dr. Victor E. Levine, Dr. Enrico Samarelli, and Dr. Alfred B. Guarnier.

The Senior Class as well as the Post-Graduate Class were well represented, and quite a number of students from other colleges were in attendance. Short speeches were delivered by Prof. Joseph Koppel, of the Faculty, Charles M. De Gaetani, President of the Junior Class, Louis Schultz, Vice-President of the Senior Class, and Edward Sher, President of the Post-Graduate Class.

The music was excellent and was furnished by the orchestra of Prof. Vincent Norman Riggio. The officers of the Junior Class and quite especially Charles M. De Gaetani, President, J. Kaplin, Vice-President, Miss J. Schillaci, Secretary, D. Rosenfeld, Treasurer and H. J. Ellen, Sergeant-at-Arms, deserve credit for their active work.

This entertainment and ball given by the Junior Class was a great success, and proves that the College of Pharmacy of Jersey City is not only making headway along educational lines, but also socially. It is expected that another entertainment including a banquet will be given during May, before graduation.

### MINNESOTA STATE PHARMACEUTICAL ASSOCIATION.

The thirty-first annual meeting of this association was held on February 9-10-11, at St. Paul. About seven hundred people attended the convention and the meeting was a very successful and enjoyable one.

President Max E. Menzel presided at the opening session on Tuesday morning and the gathering was welcomed to the city by Commissioner Henry McCall. Professor F. J. Wulling responded to the welcoming address, and the meeting was then addressed by Governor Hammond, whose complete address will be found in another column.

Mr. Donald Robertson made fitting response to the Governor and then President Menzel delivered his address.

He referred to the effects upon the trade of the European War and to the war tax laid by the government to supply the deficiency in the customs revenue; endorsed the Stevens bill; and gave qualified approval to the Harrison Anti-Narcotic legislation.

He referred to the evils of dispensing by physicians, to substitution by druggists, and suggested the adoption of a legal prescription blank to eliminate the reasons urged by physicians for dispensing their own medicines.

He criticized counter-prescribing and suggested remedial measures for raising the standard of pharmacy.

He condemned the extensive advertising in a fraudulent and misleading manner of proprietary medicines and suggested that the

journals of the trade should be critical of the advertising they accept.

He suggested an appropriation by the Association of \$25 for the relief of the Belgian pharmacists.

He praised the work of the Secretary, Dr. E. L. Newcomb, and thanked the other officers of the Association for their support.

The Treasurer's report showed a very satisfactory financial exhibit for the Association.

Secretary E. L. Newcomb made a business-like report of the duties and activities of his office. He reported the membership of the Association as 669.

The Scientific papers presented to the Scientific Section comprised the following: "The Twelve Schnessler Tissue Remedies," by Dr. Wullung; "Some Ash Determinations of Digitalis," by Mr. Haynes and Dr. Newcomb; "Drug Adulteration," by Prof. Gustav Bachman; and Dr. Newcomb presented three papers entitled "Microscopic Characteristics of some Powdered Unofficial Drugs," "Drugs produced in the Medicinal Plant Garden of the M. C. P. during 1914," and "Ash Contents of some Unofficial Drugs."

Mr. F. A. Upsher Smith read a paper upon "Compound Syrup of Hypophosphites," which paper was accompanied by samples made by suggested new formulas.

Mr. E. V. Clark gave a lecture illustrated by stereopticon views on "Hog Cholera Serum."

The following officers were elected for the ensuing year:

President, Richard J. Messing; First Vice-President, John Danek; Second Vice-President, Miss Marie Piesinger; Third Vice-President, Donald Robertson; Secretary, Dr. E. L. Newcomb; Treasurer, L. J. Merwald.

The meeting was addressed by Internal Revenue Collector Lynch and by Secretary Potts of the N. A. R. D. both of whom spoke upon the recent National legislation treating at length upon the Harrison Bill, by C. H. Turner, on "Drug Store Accounts" and by Mr. Hilbert on "The Soda Fountain."

The entertainments were the reception and ball, excursions and theatre-party for the ladies and the annual banquet which was attended by about five hundred people.

## Proceedings of the Local Branches

### BALTIMORE.

The February meeting of the Baltimore Branch of the American Pharmaceutical Association was held Wednesday evening, February the seventeenth, in the Hynson, Westcott and Company assembly room at Charles and Franklin Streets, with President E. W. Hodson in the Chair.

The minutes of the January meeting were read and approved.

As an outcome of their reading, it was ascertained that the Internal Revenue Department considers it advisable for physicians to not have their registry number printed on their prescription blanks but to write it each time, for if numbered blanks fall into the possession of unscrupulous persons they might, by using them, obtain supplies of narcotics until the fraud was discovered.

A copy of a proposed letter to the Press in regard to the Harrison act was submitted by the Secretary and was referred to the executive committee for final action.

An election of three chairmen of standing committees, postponed from the previous meeting, was held and resulted as follows:

Chairman of Committee on Membership, Charles Morgan.  
Chairman of Committee on Professional Relations, John B. Thomas.  
Chairman of Committee on Education and Legislation, Louis Schulze.

The regular program for the evening was: "The Preservation of Galenicals" by Dr. Charles C. Neal, who has given a great deal of attention to this somewhat neglected but important part of the "Day's Work," and "Helpful Hints in Dispensing and Manufacturing" by Charles C. Meyer and Otto Muelhauss, practical dispensing pharmacists, both of whom have given and are giving considerable time and much talent to developing, improving and perfecting new dispensing methods.

Mr. Neal, in reading his paper, considered particularly tinctures, fluid extracts, solid extracts and powdered extracts and during its reading and discussion, the following facts and lessons were learned.

Any deterioration, in about one-third of

the pharmacopœia preparations, is due to carelessness in preservation or storage.

A preliminary sedimentation, rather than precipitation, begins in the majority of tinctures and fluid extracts in from a few hours to several weeks after they have been made. After this usually inert sediment has ceased falling and has been, as it usually is, filtered out, the finished preparation should be practically stable, if kept in proper containers, securely stoppered, and at a uniformly moderate temperature and protected from light and heat.

Preparations high in alcohol, as a rule, keep much better than those of low proof and aqueous or weakly alcoholic ones are much more prone to deterioration.

Containers should also be practically full. A pint of fluid extract or tincture in a gallon bottle is exposed to the action of the seven and a half pints of air in the bottle and oxidation is likely to go on and even evaporation of volatile constituents may occur, resulting in the loss of valuable components and a lowering of alcoholic strength.

Loose stoppers are responsible for the same conditions and the practice of recorking a bottle with a stopper which has been pierced by a cork screw or of loosely corking it with a good cork always causes loss of something or a change of some kind, if the preparation is kept for any length of time.

Evaporation of a fluid extract to a solid extract or to even a hard dry extract has occurred as a result of this carelessness. Just the opposite effect is produced in deliquescent salts and a liquid may result.

Powdered extracts should not be poured out of their containers but should be removed with a spatula. Any of the powder left on the inside of the neck and in contact with the cork, will invariably become a solid extract, especially in damp climates, the cork sticks and is generally broken in attempting to remove it.

Solid extracts should be taken from the center of the jar and any to be replaced should be dropped in the same place and not wiped from the spatula on the side as hardening of that left there, follows.

"No sane man or official will hold a pharmacist for an allowable deterioration in the strength of Spirit of Nitrous Ether, Tincture of Iodine, Fowler's Solution, or similar preparations" was the answer of a state of-

ficial to a query, but it was pointed out that care must be exercised in making everything especially in making Spirit of Nitrous Ether in small quantities and storing it in small amber bottles.

It was also brought out, that, in these and similar cases, the new Pharmacopœia proposed to allow for a slight deficiency or increase in strength.

The general use of tap water by some pharmacists was condemned and its replacement in all preparations by distilled water was advocated.

Solution of magnesium citrate made with recently distilled water or with boiled and cooled stock distilled water has kept for months and need not be freshly prepared. A case was cited, an account of which appears in the 1911 Proceedings, of a bottle of this solution which showed no signs of decomposition, excepting darkening, after fifteen years.

Mr. Meyer suggested a unique way in which to prepare this solution.

Drop the oil of lemon calculated from the required quantity of syrup of citric acid, on the magnesium carbonate—(which must be of U. S. P. quality and not the kind marked for "Technical use only")—place this into all of the distilled water necessary for the finished product, stir well, place the citric acid crystals in a muslin bag and suspend just below the surface of the liquid. Solution will take place rapidly and when completed, add sugar, calculated from the required quantity of syrup of citric acid. Filter, bottle, charge, cap with a crown cork and label. He has kept it for eight months and it may keep longer as he feels that if it keeps that long it should keep practically indefinitely.

Stock solutions of the salts of the halogens or of the alkaloids can be kept for a long time or until used and show no signs of fungus growth if made with boiled and cooled distilled water.

Mr. Meyer brought along a wonderful assortment of apparatus, most of which is in regular use about his pharmacy.

His explanations of the uses to which they were put and his exposition of his subject was instructive, edifying and entertaining.

Among the various and sundry objects in his exhibit were:

A percolator ring with three movable pins which could be adjusted by thumb screws to

take anything from a small funnel to a large percolator.

An absorbent cotton holder made from a slide covered wood box with a hole in the bottom out of which the cotton protruded. This was kept in an elevated position and small tufts could be pulled away and used for filtering, *et cetera*, while the rest of the cotton was kept clean and protected from dust.

A box arranged similarly but with a slit in the bottom out of which the end of a roll of bandage gauze protruded. Any length desired for straining or other purposes could be pulled out and cut off with scissors.

A spring holder for rubber stamps for holding graduates bottom up and allowing them to drain without the top coming in contact with a dusty shelf.

An egg beater for quickly making emulsions.

A small sauer kraut cutter for shaping up small pieces of castile soap, utilizing the shavings for soap liniment.

A small tin machine oil can for filling capsules with oil.

A hand power capping machine for capping magnesium citrate solution bottles with crown caps, costing six dollars.

An irrigating apparatus can with tube attached was used for filling liquids into bottles.

Numbers of other ingenious things were shown and Mr. Meyer was looked upon as a near wizard.

Mr. Muelhause contributed a paper on different prescriptions and brought out that cocaine hydrochloride was incompatible with borax in solutions that contained no glycerin. Spray solutions of some of the proprietary mild alkaline antiseptic liquids which formerly formed precipitates when cocaine hydrochloride was added, do not form them now. This bears out what has long been contended, that the manufacturers of this class of medicines are likely to change their formulas from time to time and the dispensing pharmacist may get different reactions as a result.

The subject of the salting out of small quantities of essential oils in solutions of bromides or other salts in aromatic waters was brought out by a prescription which contained 8 minims of spirit of anise in a two ounce chloroform water solution of strontium bromide and resorcinol.

No method of mixing this was devised which produced a clear solution, except to add alcohol or additional water.

Replacing a part of the aromatic water in such solutions, sometimes by even a small quantity of distilled water and in others by a larger quantity, produced clear solutions.

A prescription calling for ammonium carbonate, syrup of iron iodide and mucilage of acacia caused all sorts of trouble. The best procedure under the circumstances seemed to be to use tragacanth and dissolve the carbonate in half the required quantity of water and mix the syrup with the other half, mix these two solutions and in the mixture dissolve the tragacanth.

In all cases of a precipitate occurring when two soluble substances produce it, the rule to follow is as above and to dilute the solutions of each as much as the formula will permit and then mix them.

In considering the swelling up of mass capsule prescriptions of Antikamnia and citrate caffeine and the prevention of it by using an equivalent amount of caffeine alkaloid, it was brought out that the tablets of Antikamnia and Codeine, which, heretofore, contained 18 grains codeine sulphate to the ounce, now contain only 1.8 grain to the ounce.

WM. J. LOWRY, JR., Secretary.

## CHICAGO.

The Chicago Branch of the American Pharmaceutical Association met February 16th. The topic of the evening being "The Pharmacy Preparatory High School Course."

This course has been arranged by Mr. W. M. Roberts, District Superintendent of schools of Chicago, a committee of the Executive Board of the Chicago Retail Drug-gists Association consisting of Messrs. Louis J. Pelikan, E. P. Seibert and A. C. Caldwell, Dean C. W. Patterson of Northwestern University School of Pharmacy, Dean W. B. Day of the University of Illinois, and three Chicago high school principals.

The pharmacy preparatory course has been officially adopted by the Board of Education upon the recommendation of Ella Flagg Young and is now being offered at the Chicago high schools to young men and women who have completed an elementary course equivalent to that of the

Chicago elementary schools and who desire to enter the profession of pharmacy. The course presents the following unusual features: First, students will be in attendance at school only in the morning, 8:30 to 12:30 P. M. i. e. for four study periods; second, the studies will include, in addition to English, Latin and algebra, others especially preparatory to the college of pharmacy courses, such as botany, chemistry, physics, physiology and simple accounting; third, one credit will be given each year for *one whole year* of properly supervised and tested work as an apprentice in pharmacy. The completion of the work in school will yield twelve credits and the four credits of apprentice work will provide sixteen credits, one credit short of the number required for graduation. One additional study period per day in any one of the four years would furnish this missing credit and qualify for graduation from the high school.

The two schools of pharmacy in Chicago have raised their requirements for admission to fifteen units, the Northwestern University School of Pharmacy now requiring fifteen units and the University of Illinois School of Pharmacy will require the same in 1916.

Students preparing for pharmacy who may be fortunately situated as to be able to attend school for five or six class periods each day may earn in the school the full seventeen credits required for graduation or at least the fifteen required for admission to the schools of pharmacy. It is estimated that about 500 boys now employed in drug stores in Chicago may avail themselves of this course if the druggists will give their apprentices a chance. The plan has already been favorably received by many pharmacists of the city.

One very important feature of the course is the standardization and supervision of the apprentice work. At present an apprenticeship committee has been appointed by the Chicago Retail Druggists Association to which is added a member of the Board of Education which shall supervise the apprentice work. An amendment to the Illinois Pharmacy law requiring graduation from a recognized school or college of pharmacy as a prerequisite to the examinations for registered pharmacy is to be presented to the state legislature now in session and its passage will be urged by the Illinois Pharmaceutical Association, the Illinois Board of

Pharmacy and other influential organizations of pharmacists.

In the discussion of the evening Messrs. Roberts, I. M. Light, W. B. Day, C. W. Patterson, J. H. Wells, Thos. Potts, L. J. Mrazek, L. J. Pelikan, Hugh Craig, Wm. Gray, E. N. Gathercoal and others participated. Mr. Light stated that in his opinion most of the Chicago druggists were in favor of the pre-requisite requirement yet the graduation from high school requirement for entrance to schools of pharmacy was frightening many druggists for fear that there would soon be a scarcity of clerks.

E. N. GATHERCOAL, Secretary.

#### DETROIT.

The third meeting of the Branch was held at the Wayne County Medical Building on February 19th.

Mr. Seltzer, in a report for the Committee on Legislation stated that some amendments to the present Michigan Pharmacy Law had been drawn up by the Committee, aided by Mr. Woodruff, and some of these would be presented to the Legislature at its present sitting. Modifications of the narcotic law were especially desirable, and are to be submitted for action.

Prof. W. H. Allen then called attention to the confusion existing with regard to a reliable antidote to mercuric chloride poisoning, and presented the following resolution as a motion, which was seconded by Mr. Mann, and then adopted by vote:

"In view of the fact that poisoning by mercuric chloride has increased, and the antidotes at present published do not appear to be always reliable, it is desirable that an investigation be made by the American Pharmaceutical Association to decide upon better antidotes and to publish the same so that pharmacists may have such instructions to render "first aids," pending the arrival of a physician."

Mr. Allen also exhibited a sponge, originally weighing 4 ounces, and the "mud" weighing 2½ ounces which he had washed therefrom, and which had undoubtedly been present as a filler, the sponge having been sold by weight. He objected to the reflection on the retail druggist which such conditions bring. The subject was discussed briefly by Messrs. Rohnert, Mann, and others who tended to the view that the selling of sponges is no longer an attractive

issue for pharmacists, many of whom are now discouraging it.

Mr. W. L. Scoville then presented "Three Interesting Incompatibilities" with illustrations, the first being the change of quinine to quinotoxin through the influence of organic acids, and pointing out an important incompatibility between quinine and aspirin. The second incompatibility is the decomposition of organic acids by ferric salts, induced by light, the acids being reduced to water and carbon dioxide and causing an effervescence which may burst a bottle. The third, was a combination of boric and tartaric acids in tablets which proved to be sufficiently active chemically to liberate hydrochloric acid from ammonium chloride.

Mr. C. F. Mann gave an informal talk, full of sound sense, upon the "Relationship between Clerk and Employer," pointing out the needs for mutual confidence, mutual forbearance and reasonable expectations on each side. Mr. Mann called attention to a number of details in carrying out such a policy. Mr. Weaver discussed the subject briefly, stating that he believed that both clerk and employer profited by great expectations on each side rather than by expecting little.

The Chairman announced that the next meeting of the Branch on March 19 would be addressed by Professor Edmonds of the University of Michigan on the subject of "Twilight Sleep."

WILBUR L. SCOVILLE, Secretary.

### NASHVILLE.

On January 20th the Nashville Branch A. Ph. A. met in Bloomstein's Hall with the new President, E. F. Trollinger, in the chair. On account of the illness of Secretary White, Dr. J. O. Burge was appointed Secretary *pro tem*. After the approval of the minutes President Trollinger appointed the following committees for the ensuing year: Legislation—C. C. Young, Chairman, J. B. Sand, W. R. White, S. C. Davis; Membership—M. F. Hutton, E. A. Ruddiman, J. O. Burge, L. S. Pully, D. J. Kuhn, A. J. Martin, J. Y. Walldrum; Publicity—W. R. White, J. O. Burge, J. R. McDaniels; Abstracts—R. I. Eves, F. L. Smith, Max Bloomstein, J. G. Brummitt, A. M. Webb; U. S. P. and N. F.—E. A. Ruddiman, J. M. Rogoff, Ira B. Clark, R. L. Eves, W. R. White, J. O. Burge. Pro-

gram—Dr. J. M. Rogoff, chairman, J. B. Sand, R. L. Thompson. Entertainment—S. C. Davis, A. Nickel, G. H. King, J. R. Mansfield, E. Kemper. A communication from J. W. England, offering suggestions for the coöperation of the local Branches was read and referred to the Program Committee. Dr. Rogoff, the new chairman of the Program Committee, made an interesting talk and made some suggestions on the work of that committee. He said if the retail men would attend the meetings they could be made of great value to them, almost equivalent to a post-graduate course. He suggested that all persons interested in Pharmacy in any way be invited to attend the meetings as associate members. He thought the membership committee should invite all students of Pharmacy, Chemistry and Medicine attending the schools in the city, practising physicians and others in any way interested in Pharmacy. Mr. J. E. Justice, member of the Tennessee Board of Pharmacy, said the Board, which was then in session examining a class of 51 applicants, had delegated him to represent them at this meeting. He said they were much interested in the work of the Branch and would like any suggestions from the Branch for the betterment of Pharmacy. Dr. E. A. Ruddiman then moved that the Board be requested to increase the requirements for registration from a grammar school requirement to the equivalent of one year in a high school to take effect January 1st, 1916. Upon the adoption of the motion, Mr. Justice was requested to bring the motion before the Board at the present session.

---

About one hundred and fifty druggists from the city and its environs attended the meeting of the Branch on February 17.

President Trollinger presided and the meeting was addressed by Dr. Lucius P. Brown, Inspector for the State Board of Health, and Mr. Cecil Fraser, of the U. S. Internal Revenue office, on the subject of the Harrison Bill.

After their addresses the following questions were asked of them, all of which were answered in the negative:

Can a prescription be filled by telephone order? Can a "dope fiend" register and purchase from a wholesaler? Is an eye-water an external remedy? Is a physician limited in the amount he prescribes? Are

state and city laws made void by the National law? Will holders of "permits to sell drugs" in rural districts be permitted to sell narcotics if they register with the Internal Revenue Collector?

Concerning habitual users of such drugs, Doctor Brown stated that there were 2370 persons holding permits to use such drugs in the state and he believed that number was not more than half of those habitually using them.

A committee consisting of C. C. Young, E. A. Ruddiman, D. J. Kuhn, Ira B. Clark, and C. S. Martin was then appointed to confer with Dr. Brown in drafting a new state law to conform with the federal law.

Dr. J. M. Rogoff read a paper entitled "Professional Side Lines" in which he discussed the opportunities of pharmacists for work along lines of physiological analysis, the examination of sputa, urine, etc., and urged them to activity in this direction.

Dr. Burge took advantage of the presence of many druggists to place before them the advantages of membership in A. Ph. A. and invited all to join in its work.

W. R. WHITE, Secretary.

#### PHILADELPHIA.

The regular monthly meeting of the Philadelphia Branch of the American Pharmaceutical Association was held Tuesday evening, February 9th, at the Philadelphia College of Pharmacy.

President E. Fullerton Cook called the meeting to order at 8:30 p. m. The minutes of the last meeting were read and approved.

The President appointed Mr. Joseph W. England, Prof. Henry Kraemer and Mr. Franklin M. Apple as a committee on nominations. The committee was instructed to submit nominations to be balloted upon for the officers of the local Branch at the March meeting.

Mr. Dell W. Youngken was unanimously elected to membership in the Association.

The programme was then taken up and Mr. Richard Cuthbert, Jr., presented an interesting paper on "The Professional Ideals of Pharmacy." In the absence of Dr. F. E. Stewart, his paper on "Professional Pharmacy from the Viewpoint of the Commercial Laboratory," was read by the Secretary.

Prof. Julius W. Sturmer presented "The

Current Review of Pharmaceutical Journals."

The papers submitted were discussed by Messrs. W. G. Nebig, Franklin M. Apple and Prof. Joseph P. Remington.

Not a little of the success of the meeting was due to the interesting display—One display consisted of a large number of preparations made in accordance with the new U. S. P. and N. F.; the other an "Exhibit of Filled Prescriptions," by Walter S. Froelich was of unusual excellence.

A vote of thanks was given to the contributors of the programme after which the meeting adjourned. Respectfully,

J. ED. BREWER, Secretary.

#### ST. LOUIS.

The St. Louis Branch held its regular monthly meeting in the St. Louis College of Pharmacy, February 19. Leo R. Suppan, B. Sc., presented a paper, illustrated with slides, on "The Monastic Dispensaries of the Middle Ages—A Chapter in the History of Pharmacy." Dr. Whelpley, Prof. Francis Hemm, Dr. Gustav Rehfeld, briefly discussed some phases of the Harrison Anti-Narcotic Law.

J. W. MACKELDEN, Actg. Secretary.

### Changes of Address

All changes of address of members should be sent to the General Secretary promptly.

The Association will not be responsible for non-delivery of the Annual Volume or Year Book, or of the JOURNAL unless notice of change of address is received before shipment or mailing.

Both the old and the new address should be given, thus:

HENRY MILTON,  
From 2342 Albion Place, St. Louis, Mo.  
To 278 Dartmouth St., Boston, Mass.

Titles or degrees to be used in publications or in the official records should be given, and names should be *plainly* written, or type-written.

DYER, N. ERNEST,  
From 332 Tremont St., Boston, Mass.  
To 981 A Tremont St., Boston, Mass.

SCHIRBECK, G. H.,  
From 3rd Av. and 16th St., Moline, Ill.  
To 5th Av. and 16th St., Moline, Ill.

STEVENSON, A. E.,  
From 1539 Vermont St., Lawrence, Kans.  
To 1312 Mass. St., Lawrence, Kans.

- STURMER, J. W.,  
From 17th and Cherry St., Philadelphia, Pa.  
To 1715 Cherry St., Philadelphia, Pa.
- WHITTLESEY, H. H.,  
From 240 E. Centre St., Pocatello, Idaho.  
To East Side Pharmacist, Pocatello, Idaho.
- WILLIAMS, L. S.,  
From St. Paul and 24th St., Baltimore, Md.  
To 1300 N. Caroline St., In care Morgan & Willard, Baltimore, Md.
- JOHNSON, R. V.,  
From Hosp., Columbus Barracks, Columbus, Ohio.  
To Ambulance Co. No. 8, U. S. A., Galveston, Texas.
- HERMAN, CHRISTOPHER,  
From Ft. Shafter, Honolulu, Hawaii Islands.  
To Presidio of Monterey, Cal.
- HARPER, J. E.,  
From Clearwater, Neb.  
To Spencer, Neb.
- SIZEMORE, C. R.,  
From 3024 Easton Av., St. Louis, Mo.  
To 3874 Page Blvd., St. Louis, Mo.
- BALMERT, C. A.,  
From care Cirto Chem. Co., Maywood, N. J.  
To care Emerson Drug Co., Lombard St., Baltimore, Md.
- LEFET, R. A.,  
From Box 492 Oakland, Cal.  
To Box 477, Oakland, Cal.
- LOW MARGEREY D.,  
From St. Francis Hosp., San Francisco, Cal.  
To Mrs. Harry Low, Apt. 402-1625 Polk St., San Francisco, Cal.
- WHITTLE, W. A.,  
From 308 W. Lombard St., Baltimore, Md.  
To 802 Gosuch Av., Baltimore, Md.
- HICKS, G. W.,  
From Hosp. Camp McGrath, Prov. Batangas, P. I.  
To Fort Ethan Allen, Vermont.
- KISHON, A. M.,  
From Post Hosp. F. D. A. Russell, Wyo.  
To Residence Unknown.
- O'GORMAN, T. V.,  
From 2009 Vallejo St., San Francisco, Cal.  
To Box 608, San Jose, Cal.
- REMIREZ, FRANCISCO,  
From 498 Jesus del Monte, Havana, Cuba.  
To Residence Unknown.
- REITER, HARRY LEO,  
From Camp Ward Cheny, Cavite, P. I.  
To Fort Levett, Me.
- WEBB, EVANS HALL,  
From 1421 9th St., No. Nashville, Tenn.  
To Residence Unknown.
- TOCCO, ORAZIO,  
From 95 Chrystie St., Brooklyn, N. Y.  
To 81-83 Chrystie St., Brooklyn, N. Y.
- SMITH, C. E.,  
From 640 Bedford Av., Brooklyn, N. Y.  
To 5 Beekman St., New York, N. Y.
- KUTCHBAUGH, J. F.,  
From 1707 Blue Rock St., Cincinnati, O.  
To 1510 Scott St., Covington, Ky.
- WEBSTER, J. H.,  
From 933 Champlain St., Detroit, Mich.  
To 933 E. Lafayette, Detroit, Mich.
- CORREA, J. F., JR.,  
From 47 St. Botolph St., Boston, Mass.  
To 426 Newbury St., Boston, Mass.
- BOLENBAUGH, ALBERT,  
From Dept. of Pharm., Univ. College of Medicine, Richmond, Va.  
To School of Pharm. College of Va. Richmond, Va.
- MCDIARMID, D. P.,  
From 110 Margaret St., Talladega, Ala.  
To 371 East St., Talladega, Ala.

### PRELIMINARY NOTE ON A NEW PHARMACODYNAMIC ASSAY METHOD,

CARASSIUS AURATUS (GOLD FISH) AS TEST ANIMALS FOR THE DIGITALIS SERIES.

PAUL S. PITTINGER, PHAR. D., AND CHAS. E. VANDERKLEED, PHAR. D.

"The purpose of the pharmacodynamic assay just as of the chemical assay is to secure a means of measuring therapeutic activity and to make it possible to furnish *uniform* preparations. A satisfactory method which meets these requirements may or may not involve the production of physiologic reactions similar to those for which the drug is intended to be the means of producing when used therapeutically. That the effect chosen as a means of standardization does not parallel the clinical effect sought is not sufficient to condemn the method. It is only necessary that the effect chosen as an earmark is always indicative of a good quality of the drug or preparation, and criticisms of methods on the ground that they are *toxic* methods or that the animal chosen is biologically much different than man are made only through a lack of conception of the real purpose of the pharmacodynamic test, namely, to secure *uniformity*. The determination of the real value of a drug in the treatment of disease in man is another matter entirely."<sup>1</sup>

<sup>1</sup>Quoted from "Modern Methods of Drug Standardization," by Stewart, Hitchins, Elgin, Vanderkleed and Pittenger, Monthly Cyclopedia and Medical Bulletin, January, February and March, 1913.

Since biologic standardization was first proposed in 1898 the methods of assay employed for the digitalis series have been for the most part, not new but merely quantitative applications of the methods which had been used to elicit the drugs' actions. Of the many methods proposed, with their various modifications, there are only three which have been extensively used for standardization purposes, i. e., Houghton's "12 hr." frog method, Famulener and Lyons' "1 hr." frog method and Reed and Vanderkleed's guinea pig method.

Although the above methods all give more or less satisfactory results and have been revolutionary in that they have enabled the manufacturer to supply the physician with preparations of known and definite activity, there are still some things to be desired, first, a reduction in the cost of the assay; second, a more sensitive method, and third, a method simple enough that any competent pharmacist or physician can carry it out equally as well as the expert.

Just three weeks ago, one of the authors<sup>2</sup> conceived the idea of using fish as test animals by placing them in varying dilutions of the drug and noting the minimum dilution which will cause the death of the animal in a given time.

In experiments on frogs and guinea-pigs we have always been of the opinion that after taking care of the weight and temperature factors, the most important cause of animals' dying or recovering "out of order" is the marked variation in rate of absorption. The great absorptive power of the gills of a fish, together with the fact that they contain a large number of blood vessels through which the blood circulates direct from the heart, made this animal present itself as a possible means of eliminating these variations due to absorption.

Accuracy being the prime requisite for any assay method, it was first necessary, therefore, to determine whether or not the fish would die in direct proportion to the strength of the dilution in which they were placed. Accordingly the following experiment was carried out on gold fish.

*Preparation Employed, Fld. Ext. Digitalis No. 1—Experiment No. 1.*

Dilution	Actual Amt. of F. E. Contained in 300 cc. Water	Temperature	Weight of Fish	Time Required to Cause Death
1—750	0.4 cc.	25° C.	4.3 gm.	2 hours, 1 minute
1—1000	0.3 cc.	"	4.4 gm.	3 hours, 7 minutes
1—1250	0.24 cc.	"	2.5 gm.	4 hours, 59 minutes
1—1500	0.2 cc.	"	4.0 gm.	7 hours, 2 minutes
1—1700	0.192 cc.	24° C.	4.0 gm.	9 hours, 7 minutes
1—1800	0.166 cc.	"	3.4 gm.	24 hours, 3 minutes
1—1900	0.157 cc.	"	3.5 gm.	22 hours, 16 minutes
1—2000	0.15 cc.	"	3.2 gm.	24 hours, 58 minutes

The dilutions were made with "tap water," 300 cc. placed in an 800 cc. beaker and the fish added. No attention was paid to weight or temperature other than recording the same.

The experiment was repeated with tincture of digitalis, with the following result:—

<sup>2</sup> Pittenger.

*Experiment No. 2.*

Dilution	Actual Amt. of Tinct. Contained in 300 cc. Water	Temperature	Weight of Fish	Time Required to Cause Death
1—75	4.0 cc.	27—28° C.	3.2 gm.	2 hours, 17 minutes
1—100	3.0 cc.	" "	4.1 gm.	11 hours, 45 minutes
1—125	2.4 cc.	" "	3.8 gm.	16 hours, 45 minutes
1—150	2.0 cc.	" "	2.9 gm.	20 hours, 15 minutes
1—170	1.92 cc.	" "	3.7 gm.	24 hours, 20 minutes
1—180	1.68 cc.	" "	4.0 gm.	Recovered after 30 hours

It will be noted from the above results that, although in some cases the strength of the dilutions varied only 5%, every fish died in order in accordance with the dilution of the solution in which it was placed.

Next the variation between the strength of the dilutions was still further diminished in order to determine the limit of sensitiveness of these animals.

*Preparation Employed, Fld. Ext. Digitalis No. 1—Experiment No. 3.*

Dilution	Actual Amt. of F. E. Contained in 300 cc. Water	Temperature	Weight of Fish	Time Required to Cause Death
1—1000	0.3 cc.	27° C.	4.4 gm.	2 hours, 23 minutes
1—1025	0.288 cc.	"	2.8 gm.	2 hours, 53 minutes
1—1050	0.285 cc.	"	3.3 gm.	3 hours, 40 minutes
1—1075	0.275 cc.	"	3.8 gm.	3 hours, 18 minutes

*Preparation Employed, Fld. Ext. Digitalis No. 2—Experiment No. 4.*

Dilution	Actual Amt. of F. E. Contained in 300 cc. Water	Temperature	Weight of Fish	Time Required to Cause Death
1—1000	0.3 cc.	26° C.	3.0 gm.	1 hour, 20 minutes
1—1025	0.288 cc.	"	3.8 gm.	1 hour, 25 minutes
1—1050	0.285 cc.	"	3.2 gm.	1 hour, 36 minutes
1—1075	0.275 cc.	"	2.1 gm.	1 hour, 35 minutes

*Preparation Employed, Fld. Ext. Digitalis No. 2—Experiment No. 5.*

Dilution	Actual Amt. of F. E. Contained in 300 cc. Water	Temperature	Weight of Fish	Time Required to Cause Death
1—1500	0.2 cc.	27.5° C.	2.8 gm.	1 hour, 15 minutes
1—1525	0.196 cc.	"	2.8 gm.	1 hour, 36 minutes
1—1550	0.194 cc.	"	3.0 gm.	1 hour, 10 minutes
1—1575	0.193 cc.	"	2.5 gm.	1 hour, 14 minutes
1—1600	0.187 cc.	"	3.4 gm.	1 hour, 38 minutes

Exp. No. 3 shows that with a variation as small as 2.5% in the strength of the dilutions, all but one fish died in order. Exp. No. 4 and 5, Fld. Ext. No. 2 (which was a preparation possessing greater activity than Fld. Ext. No. 1) show greater discrepancies. In this case, 3 of 9 fish died "out of order."

The facts that of Fld. Exts. No. 1 and 2, the weaker preparation gave the better results and that in Exp. No. 1 and 2 where the length of time required to cause

death was greater than in Exp. No. 4 and 5 (due to the use of a weaker preparation), not a single fish died "out of order," indicated that decreasing the strength of the dilutions would increase the sensitiveness of the test. The next experiments were, therefore, made with weaker solutions in order to prove this point.

*Preparation Employed, Fld. Ext. Digitalis No. 2—Experiment No. 6.*

Dilution	Actual Amt. of F. E. Contained in 300 cc. Water	Temperature	Weight of Fish	Time Required to Cause Death
1—1850	0.162 cc.	28° C.	2.4 gm.	1 hour, 10 minutes
1—1900	0.157 cc.	"	3.1 gm.	1 hour, 27 minutes
1—1950	0.154 cc.	"	3.4 gm.	1 hour, 49 minutes
1—2000	0.15 cc.	"	2.9 gm.	1 hour, 57 minutes

*Experiment No. 7.*

Dilution	Actual Amt. of F. E. Contained in 300 cc. Water	Temperature	Weight of Fish	Time Required to Cause Death
1—3500	0.0857 cc.	29° C.	3.1 gm.	2 hours, 58 minutes
1—3550	0.0845 cc.	"	4.0 gm.	3 hours, 55 minutes
1—3600	0.0833 cc.	"	4.2 gm.	3 hours, 48 minutes
1—3700	0.0810 cc.	"	3.8 gm.	4 hours, 30 minutes
1—3800	0.0789 cc.	"	4.6 gm.	6 hours, 6 minutes

These results show very clearly that decreasing the strength of the dilution prolongs the time required to cause death and thereby greatly increases the sensitiveness of the test. It will be noted that a variation of less than 3% in the strength of the dilutions, or, in other words, a difference of only 0.0021 cc. in the actual amount of Fld. Ext. contained in the 300 cc. water in which the fish were placed, caused a difference of one hour and 36 minutes in the length of time required to produce death.

That the weight of the fish is of no importance is clearly demonstrated by the fact that in the foregoing experiments, although some of the fish weighed more than twice as much as others, practically all died in the order of the dilution of the solutions in which they were placed.

In order to determine whether or not *large* variations in the weight of the fish would influence the results, the following experiment was carried out: The size of the large fish used made it necessary to place each animal of the series in 1000 cc. of the dilution instead of 300 cc., as was used in the preceding experiments.

*Preparation Employed, Fld. Ext. Digitalis No. 2—Experiment No. 8.*

Dilution	Temperature	Weight of Fish	Time Required to Cause Death
1—1000	27.5° C.	34.4 gm.	58 minutes
1—1000	"	27.9 gm.	52 minutes
1—1000	"	5.5 gm.	59 minutes
1—1000	"	5.0 gm.	47 minutes
1—1000	"	2.3 gm.	54 minutes
1—1000	"	3.4 gm.	55 minutes

It will be noted that, although the largest fish weighed *more than ten times as much as the smallest*, the length of time required to cause death, when immersed

in solutions of the same strength, varied but 12 minutes. These results would tend to prove conclusively that the weight of the animal can be disregarded when making tests by this method.

It was noticed that, although each series of dilutions gave concordant results within  $2\frac{1}{2}\%$ , there was a variation between the different series, in the length of time required to produce death by solutions of the same strength. This discrepancy suggested a variation due to differences in temperature. The following table shows the results of an experiment to determine the effect of temperature on the resistance of gold fish:—

*Preparation Employed, Fld. Ext. Digitalis No. 2—Experiment No. 9.*

Dilution	Temperature	Weight of Fish	Time Required to Cause Death
1—1000	38 to 39° C.	4.7 gm.	46 minutes
1—1000	26.5 to 27° C.	4.2 gm.	2 hours, 55 minutes
1—1000	12 to 17° C.	3.9 gm.	7 hours, 21 minutes

It is apparent from this single experiment that temperature is of the utmost importance and that in order to obtain concordant results it will be necessary to carry out all assays at exactly the same temperature. This can easily be accomplished, however, by immersing the beakers containing the dilutions in a constant temperature bath. The best temperature to employ still remains to be determined.

Next eight fish were placed in beakers, each containing exactly the same strength solution in order to determine the individual variation in susceptibility.

*Preparation Employed, Fld. Ext. Digitalis No. 2—Experiment No. 10.*

Dilution	Actual Amt. of F. E. Contained in 300 cc. Water	Temperature	Time Required to Cause Death
1—3500	0.0857 cc.	28.5° C.	2 hours, 47 minutes
1—3500	0.0857 cc.	"	3 hours, 12 minutes
1—3500	0.0857 cc.	"	3 hours, 18 minutes
1—3500	0.0857 cc.	"	2 hours, 59 minutes
1—3500	0.0857 cc.	"	2 hours, 43 minutes
1—3500	0.0857 cc.	"	3 hours, 8 minutes
1—3500	0.0857 cc.	"	3 hours, 4 minutes
1—3500	0.0857 cc.	"	2 hours, 51 minutes

The last fish died 35 minutes after the first one. For comparison 8 guinea pigs were injected with exactly the same dose ( $1\frac{1}{2}$  times the usual m. l. d.) per 250 gm. body weight, and it was found that the sixth pig died 1 hr. and 28 minutes after the first. The remaining two pigs were still alive at the end of 12 hours. I was unable to obtain frogs in time to make a comparison with these animals, but it is generally admitted by most workers that the variation in frogs is more marked than in guinea pigs.

In experiment No. 2 with tincture digitalis, the presence of the alcohol which was not removed did not interfere with the results. It was possible, however, that the alcohol might have increased or decreased the length of time required to cause death for the whole series. Fish were, therefore, placed in four 1-1000 dilutions of Fld. Ext. Digitalis; two with 1.5 cc. alcohol added (the amount which would be

contained in 3.0 cc. Tinct Digitalis) and two without alcohol. The results follow:—

*Experiment No. 11.*

Dilution	Time Required to Cause Death
1—1000 without alcohol	2 hours, 35 minutes
1—1000 without alcohol	2 hours, 20 minutes
1—1000 1.5 cc. alcohol added	2 hours, 7 minutes
1—1000 1.5 cc. alcohol added	2 hours, 27 minutes

It would appear from the above results that alcohol to the extent of that contained in the U. S. P. tincture does not affect the results. More extensive experiments, however, are necessary before definite conclusions may be drawn in regard to this point.

The time being limited, it was impossible to carry out all the experiments which suggested themselves in time for this preliminary report. We shall, therefore, continue our investigations in an endeavor to determine the following:—

1. The best time limit and,
2. The most suitable dilution, leading to
3. Tentative standards.
4. Action of other members of the digitalis group.
5. Extent of seasonal variations.
6. Best temperature to employ.
7. More extensive experiments on the effect of alcohol.
8. The possibility of the application of this method to standardizing biologic products, such as antitoxins, sera, etc.

SUMMARY.

The results of the foregoing experiments, together with experience with other methods so far proposed, lead to the following conclusions:—

1. Gold fish are sensitive to variations of 2½% in the strength of the dilutions of digitalis in which they are placed.
2. Variations due to differences in the rate of absorption appear to be practically eliminated by the use of these animals.
3. Decreasing the strength of the dilution, increases the sensitiveness of the test.
4. The weight of the fish may be disregarded when making tests by this method.
5. Variations in the temperature markedly influence the resistance of gold fish to digitalis poisoning.
6. The individual variation in the susceptibility of gold fish is much less than that found in guinea pigs and frogs.
7. The gold fish method is unquestionably the simplest so far proposed and can easily be carried out by those not especially skilled in the pharmacodynamic art.
8. The inexpensiveness of the assay is decidedly in its favor. Gold fish of the proper size can be purchased wholesale for from 45 to 60 cents per dozen.
9. A sufficient number of animals can be procured at all seasons of the year.

## DISCUSSION.

DR. EDWARD KREMERS:—Is the application of this method new in this country?

DR. PITTENGER:—New, so far as I know.

DR. KREMERS:—Gold fish have been used in other work?

DR. PITTENGER:—Yes, I think they have been used in other work, but so far as I am acquainted with the literature this is the first attempt that has been made to use these animals as a means of quantitatively testing the activity and thereby standardizing galenical preparation or antitoxins.

DR. KREMERS:—I think Dr. Stockberger could tell us something about that. Is he here in the room? Dr. R. H. True worked with gold fish along similar lines some years ago before he went to work in the Department of Agriculture.

DR. STOCKBERGER:—Yes, both Dr. Kahlenberg and Dr. True have conducted work with fish and tadpoles along somewhat similar lines, but the application, of course, was in an entirely different direction. The fish were used merely as a reagent, you might say, in testing the toxicity of various chemical solutions. I do not know that this method has been used in testing galenicals prior to Dr. Pittenger's work.

DR. KREMERS:—The principle was different.

DR. STOCKBERGER:—The principle was different, but the use practically was very similar.

MR. A. J. MEIER:—I would like to ask whether any experiments were carried out to determine whether or not the fish would live from twenty-two to twenty-four hours if left in ordinary water without changing at room temperature when such small amounts of water were employed?

DR. PITTENGER:—No. Such experiments were not necessary as Experiment No. 2 shows that one fish was still alive after being kept for thirty hours in only 300 cc. of a 1-150 dilution of tincture of Digitalis. Table No. 1 also shows that some fish lived for twenty-two to twenty-four hours in this amount of solution.

MR. MEIER:—Without any change of water, or getting oxygen in the water?

DR. PITTENGER:—Yes. It would not be advisable, however, to employ so small a quantity of solution if twenty-four hours should eventually prove to be the best time limit. As stated in the paper the best time limit has not yet been determined. The 300 cc. of solution were merely arbitrarily adopted at the beginning of the experiment when I had no idea as to the length of time which would be required for the fish to die when placed in the different strength solutions employed. It merely happened that some of these fish lived for twenty-four hours. If this should eventually be chosen as the time limit the quantity of the dilution would necessarily have to be increased. The fact that one fish recovered after twenty-four hours shows that such factors had no apparent effect in this time and that by using a shorter end point their effect would be practically nil.

DR. KREMERS:—Wasn't the fish which recovered seemingly dead? Is it hard to tell just when a fish dies?

DR. PITTENGER:—No it wasn't. Apparently it was just as much alive as when placed in the solution. It is very easy to note when a fish dies. It generally first turns over on its side and a little later becomes motionless.

DR. KREMERS:—Did you try to see if you could revive those which were seemingly dead by putting them in salt water?

DR. PITTENGER:—No, I did not as that would have interfered with our results. I know however, that gold fish breeders revive their sick fish by that method.

---

EXAMINATION OF CALYCANTHUS FLORIDUS FOR ALKALOIDS.

---

E. R. MILLER AND H. W. BROOKS.

---

One of the widely-known and popular plants indigenous to the Southeastern States, is *Calycanthus floridus*, a shrub from 2 to 8 feet high, growing from Virginia to Florida and Alabama.

Its chief characteristic, which has won for it almost first place among the wild flowers, is not the size and beauty of its blossoms, but rather their delightful fragrance. To this it owes the almost universal name of "Sweet Shrub."

As a medicinal plant it is not of much importance, but is said to be antiperiodic, stimulant and tonic. The bark has an agreeable, spicy, camphoraceous odor which no doubt suggested the names Carolina allspice, Florida allspice, etc.

Inasmuch as alkaloids have been discovered in the seeds of another species of

the genus, namely, *Calycanthus glaucus*,\* we decided to make an examination of the flowers, leaves and roots of the species *C. floridus*.

The roots were dried before extracting, but the flowers and leaves were used in the fresh condition.

About 200 gm. of each of the parts named were extracted by maceration with 95% alcohol which had been distilled over tartaric acid. The filtered alcoholic extract was distilled on a water bath until the greater part of the alcohol had been removed. The residue was then treated with water until no further precipitation resulted. The resinous and oily matter was removed by filtration and the filtrate evaporated to a small volume on a water bath. In the case of the root this aqueous extract was rather milky in appearance, and was cleared up by shaking out with ether. The aqueous liquid was then made slightly alkaline with ammonia and extracted in succession with ether, chloroform, petroleum ether and benzene. After evaporation of the immiscible solvent the residue was treated with a small amount of water acidulated with dilute  $H_2SO_4$ , and tested with general alkaloidal reagents. The following results were obtained:—

SOLUTION FROM ETHER EXTRACT.

	Roots	Flowers	Leaves
Potass mercuric iodide	Slight ppt.	Yellowish White ppt.	Heavy White ppt.
Co. Solution iodine...	Reddish ppt.	Heavy Brown ppt.	Red ppt.
Potass Bismuth iod...	Red ppt.		
Tannic acid.....	No ppt.	No ppt.	No ppt.
Phosphomolybdic acid	No ppt.	No ppt.	Heavy White ppt.
Picric Acid.....	No ppt.	Yellow ppt.	Yellow ppt.

The chloroformic extract of the flowers gave precipitates with phosphomolybdic acid and solution iodine compound. The petroleum ether extract of the flowers gave a ppt. with sol. iod. comp. The benzene extract of the leaves gave a white ppt. with potass. mercuric iod.; a red ppt. with sol. iod. co. and a greenish-yellow with picric acid, and the ether extract from the leaves gave a heavy white ppt. with potass. mercuric iod.; a red ppt. with co. sol. of iodine; a heavy white ppt. with phosphomolybdic acid and a yellow ppt. with picric acid.

The results obtained make it highly probable that the plant contains alkaloids, especially in the leaves, the extract from which produced the most abundant precipitation with the alkaloidal reagents. Considering the nature of the solvents used in preparing the solutions to be tested it is scarcely probable that enough protein matter could have been present to give the abundant precipitation that was obtained in several cases.

The subject will be further investigated as soon as sufficient material can be obtained.

## THE ANALYSIS OF CIGARETTES, CIGARS AND TOBACCO, AND THE USE OF LLOYD'S REAGENT IN THE DETERMINATION OF NICOTINE.

—  
AZOR THURSTON.  
—

### INTRODUCTION.

Some six months ago while in conversation with Hon. S. E. Strode, Commissioner in charge of the Dairy and Food Division of Ohio, the question of adulteration of cigarettes and other tobacco products came up and the statement was made by some one present that large quantities of tincture of opium were being purchased by manufacturers of this line of goods. An investigation was therefore ordered, not only as to opium, but as to medicinal substances in general. It fell to the lot of the writer to make whatever investigation as was deemed necessary.

The most natural thing to do was to look up the literature on the subject and, to my surprise, I was unable to find a published account of the analysis of cigarettes or cigars, although other tobacco products were fairly covered in reference to nicotine and some other constants. I therefore wrote to the Bureau of Chemistry, U. S. Department of Agriculture, where one naturally expects to obtain methods of analysis of practically everything, and again I was doomed to disappointment, the reply indicated that methods had not been developed for making analyses of cigarettes, although the department had made a few examinations of cigarettes with the view of determining whether or not they contained opium or arsenic.

I found in Wiley's *Agricultural Analysis*<sup>1</sup> a statement in reference to opium and cigarettes as follows:—"It is believed, however, that opium is not often found in manufactured tobacco, and it has never been found in this laboratory in cigarettes, although all the standard brands have been examined for it."

I at once took the matter up with Dr. Wiley by correspondence, and received a reply as follows:—

"As far as I know opium, arsenic, etc., have never been found in cigarettes. This is a rumor which is constantly being floated, but is without general foundation. The cigarettes are harmful enough in themselves without seeking this extreme evil in them. None of the results referred to were ever published as far as I know. You can perhaps get more definite information concerning this investigation from Mr. McElroy himself, as he is a practicing chemical patent attorney in this city. The address is K. P. McElroy, 918 F Street. I have no special data on the subject of the cigarette evil, but am unalterably opposed to the use of tobacco in any form, as I consider it an unclean, unhealthy habit which diminishes the vitality and the efficiency of the user, and is, moreover, an imposition on the public who do not use it."

Upon receipt of Dr. Wiley's letter it appeared I would corner the information I most desired, and I immediately wrote to Mr. McElroy for more light upon the subject. He promptly replied as follows:—

"I regret to say that I can give you very little information concerning the analyses of cigarettes at the present day. What analytical work I did was done very many years ago and the results were never published to my knowledge, having been made for the information of a congressional committee.

"About all I remember of the matter at present is that in the twelve or thirteen brands I analyzed I did not, of course, find morphine, arsenic, and other alleged ingredients. Neither did I find Alfalfa, a common rumor to the contrary notwithstanding. I found considerably more nicotine than expected."

<sup>1</sup> Wiley's *Agricultural Analysis*, Vol. 111, 597.

During this correspondence the inspectors had delivered to me a number of samples for analysis, and I decided to begin the investigation along lines that appeared most desirable the details of which follow.

*Preparation of Samples:*—The samples were not dried except as they were kept in the laboratory at a temperature of about 25° C. Any attempt at artificial drying might be at the sacrifice of nicotine and was, therefore, not attempted. The samples were next powdered, so as to pass through a number 20 sieve. If finer so much the better, but it is some difficulty to obtain a powder of this fineness, even after passing the sample through a meat-chopper several times. In case of cigarettes the papers were removed and all particles of the filler carefully dusted off so as to obtain the papers as free from the filler as possible. Separate analyses being made of the papers.

*The Analysis:*—Determinations were made as follows:—Nicotine, ash, water soluble ash, water insoluble ash (by difference), hydrochloric acid insoluble ash, alkalinity of water soluble ash, alkalinity of water insoluble ash, opium and other drugs.

The same determinations were made of the papers, except for nicotine, and further tests were made for nitrates in the papers.

No. 1642 was a bleached tobacco used for the manufacture of cigarettes.

#### METHODS OF ANALYSIS.

*Nicotine*—As the amount of nicotine present determines the strength of the tobacco this estimation is of great importance.

Numerous methods have been proposed for the determination of nicotine, but they all practically are included in three divisions.

The Küssing's method is the official method of the Association of Official Agricultural Chemists and consists in making the sample alkaline and extracting with

ether, evaporating the ether, and distilling the extract in a current of steam. The distillate is titrated with standard acid.

The Keller<sup>3</sup> method—The nicotine is extracted with proper solvents and air passed through the extract, to expel ammonia, and the extract finally titrated with standard acid.

The Bertrand & Javillier<sup>4</sup>, or Silicotungstate method—As in the Kissling or similar methods the nicotine is extracted from the tobacco and the extract distilled in a current of steam and then the nicotine precipitated from the distillate as nicotine silicotungstate, a rose white salt with the following formula:— $2C_{10}H_{11}N_2 \cdot 2H_2O \cdot SiO_2 \cdot 12WO_3 + 5H_2O$ . This salt on being ignited leaves a residue of  $SiO_2$  and  $WO_3$  from which is calculated the weight of nicotine originally present. This method of analysis was used for the determination of nicotine as herewith tabulated except the first extracting was omitted and the nicotine determined in the tobacco by directly distilling in a current of steam and following out Chapin's<sup>5</sup> directions modified to read as follows:—Weigh out exactly 5 grams of the sample and wash, with about 25 cc. of water, into a 500 cc. Kjeldahl flask; add 1 to 1½ grams of paraffin, a few small pieces of pumice and 5 cc. saturated solution of sodium hydroxide. Distil in a rapid current of steam, through a condenser and adapter, into 10 cc. of dilute hydrochloric acid (14) into a 1500 cc. flask. When distillation is well started, apply heat to the distilling flask so as to keep the volume as low as practical. Distil until the distillate measures about 1000 cc., or when treated with a drop of silicotungstic acid and a drop of hydrochloric acid no opalescence is produced. Make the distillate up to exactly 1000 cc., or some other convenient volume, with distilled water. Filter and place 100 cc. of filtrate in a 250 cc. beaker and add 3 cc. dilute hydrochloric acid (14) or more if necessary to make the solution distinctly acid. Add 1 cc. of a 12 per cent. solution of silicotungstic acid for each 0.01 gram nicotine supposed to be present. Stir thoroughly and let stand for eighteen hours. Filter on an ashless filter and wash with dilute hydrochloric acid, 1 cc. concentrated acid to 1000 cc. water, until the filtrate is free of silicotungstic acid. Transfer the wet paper and precipitate to a weighed platinum crucible, using a scrap of moistened filter paper to transfer any precipitate which may have crept up the sides of the funnel; dry, carbonize and break up the precipitate with a platinum wire and finally cover the crucible and apply full heat of a Bunsen burner for fifteen minutes. Cool in a desiccator and weigh. The weight of the residue multiplied by 0.114 afford the nicotine in the aliquot taken for precipitation, and from this amount the percentage may be calculated.

Instead of precipitating with silicotungstic acid Emery<sup>6</sup> proposed to determine the amount of nicotine in the distillate by polarization and others have proposed to precipitate the nicotine with mercuric potassium iodid. It appears to the writer that the silicotungstic method is less liable to errors and it is susceptible of concordant results on duplication.

#### THE USE OF LLOYD'S REAGENT IN THE DETERMINATION OF NICOTINE.

This is merely a preliminary report on the determination of nicotine with Lloyd's Reagent as lack of time has prevented a thorough investigation, although

<sup>3</sup> J. Chem. Soc., 1899, Vol. 76, 11, 193; Proc. A. Ph. V., 1900, Vol. 48, 392.

<sup>4</sup> J. Chem. Soc., 1909, Vol. 96, 11, 450; Chem. Abs., 1909, Vol. 3, 1382 and 2107.

<sup>5</sup> U. S. Dept. Agr. Bureau of Animal Industry Bulletin 123, 1907.

<sup>6</sup> J. Am. Chem. Soc., 1901, Vol. 23, 1113.

sufficient work has been done to predict that a successful method might be worked out.

So far I have been unable to make close duplications and without going into details as to the different experiments made I will give the amount of nicotine found by the use of Lloyd's Reagent and by using silicotungstic acid:—

No.	Silicotungstic Method	Lloyd's Reagent
4524	2.05	1.80
4525	1.93	1.99
4527	1.45	1.99
4530	1.52	1.18
		2.06
4528	1.59	1.65
4535	1.97	1.51
4529	1.98	1.75
		1.99
4532	1.44	1.97

There have been a number of interesting articles<sup>7</sup> published in reference to Lloyd's Reagent which should be read by interested parties.

All methods of extracting the alkaloids of tobacco, includes the four alkaloids,—nicotine, nicotine, nicotine, and nicotine. The three latter existing in such small quantities that they do not make much practical difference and usually the total amount of alkaloids extracted from tobacco is considered nicotine; however, as nicotine and nicotine are volatile in a current of steam and the other two are not, by the distillation method the two non-volatile alkaloids are eliminated.

I find sulphomolybdic acid gives a blue coloration with nicotine, which might be easily mistaken for morphine, as practically the same coloration is produced with this reagent with both alkaloids. A drop of the reagent should be directly applied to the pure nicotine or to the solids containing nicotine—such as tobacco and tobacco extracts. The color is produced more rapidly if the substance is slightly warmed.

*Ash*:—Weigh exactly 2 grams of the sample in a platinum pan and incinerate. Any particles carbon can be removed by adding a few drops of water to the ash and after drying ignite for a few minutes. The average ash obtained from three samples of leaf tobacco was 15.50, from two samples of cigars 21.22, and from twenty-eight samples of cigarettes 18.81 *per cent*.

*Alkalinity of Water-Soluble and Water-Insoluble Ash*:—The water-soluble ash is determined by dissolving, in hot water, the soluble portion from the ash as above determined and titrating with N/10 acid, using methyl orange as indicator. The alkalinity of water-soluble ash is reported as the number of cubic centimeters of decinormal acid required to neutralize the ash from one gram of the sample.

The water-insoluble ash is dissolved in 5 cc. normal hydrochloric acid and the excess of acid estimated by titrating with decinormal alkali. The number of cubic centimeters of decinormal alkali used deducted from 50 will give the alkalinity of the water-insoluble ash. In a few cases it will be necessary to use 10 cc. normal acid as the alkalinity occasionally runs very high.

*Hydrochloric Insoluble Ash*:—Is determined by adding concentrated hydrochloric acid to the solution after determining alkalinity of the water-insoluble ash. Pass the bulk of the solution through an ashless filter and add concentrated hydro-

<sup>7</sup> J. Am. Chem. Soc., 1913, Vol. 35, 837. Am. Druggist, 1913, Vol. 61, 234.  
J. Am. Ph. Association, 1914, Vol. 3, 625-630.

chloric acid to the residue and wash the insoluble portion on the filter with distilled water. Incinerate the filter with residue in a platinum crucible. Cool, and weigh.

*Opium and Other Drugs*.—Macerate a few grams of the sample with alcohol for two or three hours. Filter and evaporate the filtrate to dryness. Extract the residue with dilute sulphuric acid and complete the investigation by shaking out according to Fuller's<sup>8</sup> scheme of analysis for separation and detection of substances in medicinal products.

The current report is that cigarettes contain opium or some form of "dope"; however, the brands I examined were free of added medicinal substances, barring calcium, magnesium and nitrates found in the papers.

Referring, again, to sulphomolybdic acid test for nicotine, I wish to call your attention to the fact that morphine might be easily mistaken for nicotine. For instance, after shaking out the alkaline solution with petroleum ether, for nicotine, and then with a mixture of chloroform and alcohol (2 : 1) for morphine and evaporating the solvent I added a drop of sulphomolybdic acid to the residue and a blue color was at once produced, indicating morphine. As the brand of cigarettes tested was manufactured by a company of high reputation it did not appear probable they would use opium in their goods. Therefore, I extracted the nicotine from a distillate of known purity and applied sulphomolybdic acid to the residue and the blue coloration was at once produced.

If, for any reason, only one test is to be applied to the extract for the detection of morphine, use formaldehyde-sulphuric acid (10 cc. formaldehyde solution to 50 cc. concentrated sulphuric acid). A deep purple color indicates morphine and no coloration is produced with nicotine.

#### CIGARETTE PAPERS.

So far as I know nearly all cigarette papers have chemical fillers added, presumably to improve their burning qualities; however, if the ingredients are harmless there should be no particular objection to their use.

Prominent manufacturers kindly furnished the analysis of two brands of cigarette papers and, as I have not been able to find this subject covered in the published literature I consider them of sufficient interest to reproduce same in this paper.

#### "ANALYSIS OF CIGARETTE PAPERS.

	Austrian	French

Fiber .....	linen	linen
Organic fillers .....	starch	starch
Soluble constituents .....	alkaline	alkaline
Carbonates in filler as CO <sub>2</sub> at least .....	2.00	2.00

#### REMARKS.

<sup>8</sup>The papers were all what would be technically known as 'very moderately' sized as they carry small amount of starch, along with the filler which was composed of varying amounts

<sup>8</sup> Fuller's Qualitative Analysis of Medicinal Substances.

of calcium, aluminum and magnesium oxides and carbonates. There was also present small amounts of iron and silica which would be present from the wash water used in the preparation of the pulp or in many other ways.

"The fiber present in the pulp was found to be composed of linen, very well pulped except for a very few bunches of undigested or unbeaten fiber which it is impossible to overcome. No test for other fibers was obtained. No acids, sulphur compounds or chlorine was found which might have come from the process of manufacture. The paper gave an alkaline reaction due to the filler used which was composed of calcium, aluminum and magnesium carbonates and oxides. The carbonates present were equal to at least 75% of the ash and probably more, but it was impossible to determine this very accurately. No impurities other than those mentioned were found. The moisture found was of varying weight, due to the fact that paper of the variety examined has a tendency to hold moisture proportionate to the humidity of the atmosphere of the date of examination."

I wish to call particular attention to the small amount of ash shown by these analyses compared with the amount actually found by the writer in twenty-eight samples which yielded an average percentage of 14.93.

#### NITRATES IN PAPERS.

It appears that the majority of manufacturers object to paper containing nitrates.

Nitrates may be detected by applying the diphenylamine test as follows:—Take one drop diphenylamine test solution on a glass rod and draw the rod lightly and quickly across the paper. Hold the paper to the light and within five or ten seconds a blue coloration is produced in case nitrates are present. If a large quantity of the nitrate is present the coloration forms immediately. The diphenylamine test solution may be prepared after Withers & Gray's formula,<sup>9</sup> which is as follows:—0.7 gram of diphenylamine is dissolved in 60 cc. concentrated sulphuric acid and 28.8 cc. of distilled water. The mixture is thoroughly cooled and 11.3 cc. concentrated hydrochloric acid are added slowly.

The papers of only four brands out of twenty-eight tested, responded to this test for nitrates.

In closing, I wish to acknowledge the helpful suggestions of Prof. John U. Lloyd while experimenting with Lloyd's Reagent; also to those who kindly and promptly replied to my letters when seeking information on certain points and to the manufacturers in furnishing data in reference to cigarette papers.

---

#### ESTIMATION OF CALOMEL.

---

R. I. GRANTHAM:

---

The iodometric method for the estimation of calomel is the most expeditious and convenient one. This method, however, cannot be applied generally, especially in the analysis of calomel tablets or similar preparations which contain in addition to the mercury salt various other ingredients. In order to find a reliable method for estimating the calomel in such products the following methods were tried by which reliable results were obtained:—

#### METHOD I.

0.3 gm. of calomel or an amount of the powdered tablets equivalent to 0.3 gm. of calomel is transferred to a 6 ounce glass stoppered bottle. Any alkali present

---

<sup>9</sup> J. Am. Chem. Soc. (1911), Vol. 33, 708.

is neutralized with acetic acid and about 5 cc. of chloroform, 20 cc. of N 10 iodine solution and 5 cc. of potassium iodide solution (1:1) are added. The mixture is shaken occasionally for 15 minutes and the excess of iodine is then titrated with N 10 sodium thiosulphate solution. Each cc. of N 10 iodine solution corresponds to 0.0236 gm. or 0.364 grains of calomel.

#### METHOD II.

0.2 gm. of calomel or a corresponding amount of the powdered tablets is transferred to a 4 ounce Erlenmeyer flask, mixed with 0.5 gm. of potassium chlorate and 15 to 20 cc. of 10 *per cent.* hydrochloric acid. The mixture is digested on a steam-bath for 15 minutes and is then filtered into an 8 ounce glass stoppered bottle. The solution is neutralized with caustic alkali and a sufficient quantity of the alkali is then added to obtain an excess equivalent to about 20 cc. of normal caustic alkali. After the addition of 3 cc. of formaldehyde solution (37 *per cent.*), the mixture is shaken well and is then allowed to stand for 15 minutes. It is then made acid with acetic acid and the metallic mercury which is formed estimated iodometrically as given in Method I. Each cc. of the N 10 iodine solution corresponds to 0.0118 gm. or 0.182 grains of calomel.

#### METHOD III.

0.3 gm. of calomel or an equivalent amount of the powdered tablets is treated with potassium chlorate and hydrochloric acid as just given. The mixture is filtered into a large beaker, the filter washed well with water and the filtrate is made alkaline with ammonia water. After the addition of a large excess of acetic acid and one to three grams of sodium or potassium oxalate to the filtrate, the mixture is boiled, stirring constantly in order to prevent bumping. After allowing the mixture to settle, it is filtered. The precipitate is washed three times with hot water by decantation, is transferred to a filter and is washed with hot water until free from chlorides, using for this purpose about 150 cc. of water in all. The filtrate and wash-water are then heated to about 80° and the mercury is precipitated with hydrogen sulphide gas and estimated as mercury sulphide in the usual way.

Although Method I, originated by Hempel, is a very expeditious and reliable one it cannot be applied as already pointed out in every case. It is essential that chloroform and acetic acid be used, as I have found that in the absence of chloroform, when tablets are made with mineral oil as a lubricant, the mercury globules are covered with a thin coating of the oil and the iodine solution is thus prevented from acting on the mercury. If such is the case the results naturally will be low. The acetic acid is used in order to dissolve any alkaline salts present.

Method II is devised as a check of Method I, and although it is somewhat more complicated it may be considered as giving more accurate results for general use. Most of the foreign matter present is oxidized by the chlorine liberated from the potassium chlorate by the hydrochloric acid.

In this process the calomel is converted into mercuric chloride, the latter reduced by the formaldehyde to metallic mercury, which in turn is converted by the iodine solution into mercuric iodide. From the amount of iodine solution used for this purpose, found by titrating back the excess of iodine solution, the amount of calomel can easily be estimated.

The third method is well adapted for examining tablets which contain coloring matter, or pills which contain resins, gums and similar substances. The sodium or potassium oxalate is added to eliminate the hypochlorite which is formed during the reaction and which would cause a precipitation of sulphur when conducting the hydrogen sulphide into the solution obtained. Naturally all insoluble matter should be eliminated by filtration before the mercury is precipitated by the hydrogen sulphide. Calcium phosphate which is frequently applied as a diluent in making tablets of this kind is also precipitated as oxalate.

These methods were applied to mixtures of various composition, and also to various kinds of tablets. The mixtures were the following, the amount of ingredients being expressed in grams. The following results were obtained:—

	Mixture No. 1	Mixture No. 2	Mixture No. 3	Mixture No. 4		
Calomel .....	5 gms.	5 gms.	5 gms.	2.5 gms.		
Sod. Bicarb.....	5 gms.	10 gms.	25 gms.	2.5 gms.		
Starch .....	1 gm.	2 gms.	5 gms.	5 gms.		
Talcum .....	1 gm.	2 gms.	5 gms.	5 gms.		
Glycolene .....	0.5 gm.	1 gm.	2 gms.	2 gms.		
Prec. Calc. Phos. q. s. ad.....	25	50	100	100		
Calomel in Mixtures.....	20%	10%	5%	2.5%		
			Mixture No. 5	Mixture No. 6		
Calomel .....			2.5 gms.	2.5 gms.		
Milk Sugar q. s. ad.....			50 gms.	10 gms.		
Calomel in Mixtures.....			5%	25%		
	1	2	3	4	5	6
Method I.....	99.1%	98.0%	100 %	96 %	99.5%	99.1%
Method II.....	99.8%	100 %	100.9%	96.7%	99.8%	99.2%
Method III.....	98.3%	99.6%	97.2%	95.1%	100.1%	100 %

Three kinds of tablets were examined and the results obtained by the three methods represent the following amount of the theoretical amount present:—

Tablets Method I.....	90 %	94 %	106%
Method II.....	97.3%	100.1%	98%
Method III.....	98.2%	101 %	99%

## SOME FACTORS IN DRUG ABSORPTION IN FROGS.

W. F. BAKER, M. S., M. D.

Among the objections that have been urged against the frog-heart assay method for the digitalis bodies, the principal ones are the factor of absorption and the time-limit. Of these, the factor of absorption is undoubtedly the more important, the time-limit being dependent upon the rate of absorption.

The manner in which various fluids are absorbed from the lymph sac or the absorption prevented, has not been determined. Experiments and experience have demonstrated, however, that the majority of healthy frogs will absorb from the ventral lymph sac, in a period of one hour, a quantity of fluid equal to about 0.015 cc. per gram of body weight.

Focke has demonstrated that enough of the digitalis bodies may be absorbed in five to twenty minutes to produce the characteristic digitalis heart and has taken twenty minutes as the time-limit for his method. Magnus, using another method, has extended the time to one-half hour, Famulener and Lyons to one hour, and

Houghton to twelve hours. Not infrequently, when assaying preparations by the one-hour method and by the twenty-four method, I have found that out of a series of ten apparently healthy frogs, in not more than one or two frogs would the absorption be complete. At another time, using the same preparation or solution and frogs of the same lot, and under apparently the same conditions, absorption would be complete in every instance. If this non-absorption was but rarely observed, the cause might be attributed to that ever-ready idiosyncrasy. Occurring as it does at times in nearly every member of a series, it appears to be more than an individual peculiarity, and becomes a factor of great importance in this assay method.

While poor absorption may be met with during any time of the year, it is especially likely to occur during the Spring and late Fall. Certain preparations are very prone to meet with poor absorption, as German digitalin, digitoxin and preparations containing acetic acid or glycerin.

In a series of experiments with strychnine and ouabain, frogs placed in these solutions quickly (3 to 15 minutes) absorbed enough of the drug through the skin to produce the typical poisoning. The same results were secured after pithing (brain only for strychnine—brain and cord for ouabain). In another series, in which the solutions were injected into the lymph sac after pithing, complete absorption had taken place within 60 minutes in some frogs, while with others there had been but little absorption. In another series of experiments, a flap was made from the skin of the abdomen, and the drug painted on the under surface of the flap, that is, the lining of the lymph sac, and in others painted on the surface of the abdominal muscles, care being taken to prevent the solution touching the skin. Typical poisoning was produced in all cases except with ouabain on the inner surface of the flap, when in only two instances was the ouabain action observed in a series of twelve experiments. In still another series after pithing, the skin was removed from the hind legs and the frog suspended so that these were in solutions of strychnine or ouabain. The typical poisonings were produced. This did not occur with strychnine if a ligature was previously placed around the base of the heart.

From these experiments it would appear that absorption, of these two drugs at least, may take place from the outer or inner surface of the skin or from the surface of the muscles. The mechanism of absorption or prevention of absorption is not under control of the central nervous system.

Frogs kept in the light appear to absorb better than those kept in the dark. Absorption occurs more readily at higher temperatures, although at a temperature of 30° C., for one hour absorption is not always complete.

It was suggested that perhaps the manner in which the frogs were kept might have something to do with the absorption. Several series of experiments were made upon lots of frogs of testing them as soon as they arrived and again after they had been kept for some weeks under uniform conditions. The main points brought out by this work were, that different lots of frogs varied in their susceptibility to ouabain and digitalis when first received, and some lots absorbed more readily than others.

To determine if the amount of moisture present in the frog influenced absorption, frogs were kept in dry cases until they had lost 10, 25 and 50 *per cent.* of

their weights and then solutions were injected into the lymph sacs. It was found that these frogs absorbed even less readily than the controls kept in wet cages.

In another series of experiments it was found that .9 *per cent.* salt solution was more readily absorbed than distilled water, and 25 *per cent.* alcohol more readily than the salt solution. 50, 75 and 95 *per cent.* alcohol is fairly well absorbed, but not so readily as the 25 *per cent.*

Frogs which are plainly diseased (red-leg disease) may absorb quite readily, while others which, to all appearances are quite healthy, may not absorb at all. In two instances of this kind, I obtained roughly 25 *per cent.* more fluid from the ventrol lymph sac than I had injected. I believe, however, that the matter of absorption is largely due to the health of the frogs and the condition under which they are kept, and if proper attention is paid to the handling, cleansing and storing of the frogs, but little difficulty will be experienced with poor absorption. If, when assaying, all frogs are discarded which contain an excess of fluid in the lymph sac one hour after being injected, quite uniform and reliable results are obtained by the one-hour frog-heart method.

## STILLINGIA SYLVATICA.

---

E. R. MILLER, R. I. BROOKS AND C. P. RUTLEDGE.

---

The root of *Stillingia sylvatica* has been a popular remedy in the Southern States for more than a century. It was first introduced to the medical profession by Thomas Young Simons, in an article published in 1828, in the American Medical Recorder.

In 1846, Dr. H. B. Frost<sup>1</sup> published a paper on *Stillingia* in which he considered it "not very far inferior to mercury in its action upon the capillary and secreting vessels in changing their morbid states or conditions."

In 1850, the root of *Stillingia sylvatica* was introduced into the United States Pharmacopœia and has occupied the position of an official remedy ever since.

Concerning the value of the drug there is very great divergence of opinion, but it is still largely used in domestic practice, chiefly as an alterative, and by the medical profession, especially in the form of certain proprietary remedies of which it forms an ingredient. Notwithstanding its long use, however, there is very little known concerning the chemistry of the plant, the pronounced acidity of the drug being attributed to a volatile oil, a fixed oil and a resin called sylvacrol.

*The Volatile Oil:*—The term "oil of stillingia" has been applied to two products of very different character, meaning on the one hand a preparation obtained from the root by steam-distillation and on the other an alcoholic or ethereal extract of the same. To add to this confusion there are contradictory reports concerning the presence of volatile oil in the root. Thus, W. Saunders<sup>2</sup> extracted five pounds

---

1. Am. Jour. Pharm., 20, 306.

2. Proc. A. Ph. A., 1868, 460; Am. Jour. Pharm., 41 (1869) 149.

of the dried root with alcohol and obtained five and a quarter ounces of an extremely thick oil. J. H. Harmanson<sup>3</sup> distilled the root with water and obtained an opalescent distillate, but no volatile oil. On the other hand, W. Bichy<sup>4</sup> distilled 100 gm. of the powdered drug and was able to separate from the distillate 3.25 gm. of a yellowish oil lighter than water. This latter result is widely quoted in text-books and works of reference.

With the object of obtaining a quantity of the volatile oil for a chemical investigation, we collected about 150 pounds of the fresh root and after a few weeks subjected it, in a coarsely comminuted condition, to steam distillation. The distillate was acid to litmus and possessed a rather disagreeable odor, but, much to our surprise, only a few drops of a slightly yellowish oil, lighter than water and of disagreeable odor, could be separated from the distillate. A large part of the distillate was neutralized with sodium bicarbonate and shaken out with ether. After removal of the ether only a small residue was obtained. The distillate which had been neutralized and extracted with ether was evaporated on the water bath to a small volume, slightly acidified with sulphuric acid and distilled with steam, but the amount of acid obtained was too small to be examined further. Just what influence the time of collection, method of drying and age of the drug may have on the yield of volatile oil we are unable to say, but we are inclined to doubt the possibility of obtaining 34% of volatile oil from unadulterated *stillingia* root under any circumstances.

*The Alkaloid*.—Bichy's analysis of the root seemed to show, in addition to the ordinary constituents of plants, the presence of an alkaloid (*stillingine*). E. G. Eberhard<sup>5</sup> made a chemical examination of *stillingia* root in 1891, and concluded that no alkaloid is present. In his examination the drug was extracted in three different ways, one of which was a repetition of Bichy's process, but in the final test for alkaloids he applied, in two cases, only Mayer's reagent and in the other Mayer's reagent and picric acid. Since Mayer's reagent does not form a precipitate with all known alkaloids, and picric acid may fail to give a precipitate with alkaloids in weak solution, Eberhardt's experiments may be considered as not conclusive.

In order to obtain further knowledge on this question we carried out the following experiments:

1. 220 gm. of the fresh root, finely comminuted, were extracted by maceration with hot water acidulated with acetic acid. The liquids obtained by straining and expressing were united, filtered and evaporated by gentle heat to a semi-solid mass. This was extracted with alcohol, filtered, the alcohol evaporated off and the residue concentrated to a small volume. This was mixed with 200 cc. of distilled water, filtered, made alkaline with ammonia, extracted with ether and the ethereal solution shaken with a small amount of distilled water acidulated with  $\text{H}_2\text{SO}_4$ . This solution gave characteristic precipitates with the following alkaloidal reagents:

Wagner's reagent, Dragendorff's reagent, Scheibler's reagent and tannic acid.

3. *Am. Jour. Pharm.*, 54 (1882): 387.

4. *Idem*, 57 (1885): 529-531.

5. *Lilly's Bull.*, No. 17, November, 1891.

2. 150 gm. of fresh root were extracted with hot water acidulated with acetic acid. The total liquid obtained by straining and expressing was concentrated to about 40 cc., made slightly alkaline with KOH and distilled, the distillate being received in a small amount of water acidulated with  $\text{H}_2\text{SO}_4$ . The distillate was evaporated on a water bath to about 5 cc. and then tested with the following results:—

Wagner's reagent gave a reddish yellow ppt.; Dragendorff's reagent gave a yellowish brown ppt.; Scheibler's reagent gave a very abundant white ppt.; Picric acid gave a lustrous yellow crystalline ppt.; Tannic acid gave a yellowish white ppt.; Platinum chloride gave a yellow ppt.

3. 250 gm. of the fresh root were cut into very fine pieces and extracted by maceration with purified 95% alcohol. The alcoholic solution was slightly acidulated with HCl and the alcohol distilled off on a water bath and the residue concentrated by moderate heat to a small volume. This was mixed with 25 cc. of distilled water, filtered, the filtrate made slightly alkaline with KOH and shaken out with ether, the ethereal solution evaporated to small volume and then shaken with 5 cc. of distilled water acidulated with  $\text{H}_2\text{SO}_4$ . This solution gave characteristic precipitates with Wagner's, Dragendorff's, and Scheibler's reagents.

Following the extraction with ether, chloroform was used and an aqueous acid solution prepared in the same way. The above-named reagents gave precipitates with this solution, also, but in smaller amounts.

4. About nine kilos of the fresh root were subjected to pressure, yielding a juice which was free from acidity, but had a slightly sweet taste and a disagreeable nauseating odor. This juice was allowed to evaporate to dryness spontaneously. The residue was extracted with 95% alcohol, filtered, the alcohol evaporated off and the residue reduced to a small volume on a water bath. On the addition of water an oily layer separated. This had a disagreeable odor and was soluble in alcohol, ether and chloroform. The mixture was shaken up with ether, then made alkaline with KOH and again extracted with ether. The two ethereal solutions were concentrated and separately shaken with a small amount of water acidulated with  $\text{H}_2\text{SO}_4$ . With the usual alkaloidal reagents these solutions gave only very slight reactions.

5. About eleven kilos of the fresh root were extracted by the method given in experiment No. 2. From the ethereal solution obtained from this extract, after the addition of two or three drops of HCl, the greater part of the ether was removed by distillation and the remainder allowed to evaporate spontaneously. A brown residue was obtained. This was treated with acidulated water, filtered and tested with alkaloidal reagents. Each of the following gave a decided precipitate:—

Compound solution of iodine, Pot. bismuth iodide, Pot. mercuric iodide, Pot. cadmium iodide, Phospho-tungstic acid, Picric acid, Tannic acid, Phosphomolybdic acid, Mercuric chloride, Platinic chloride.

The remainder of the liquid which gave the above-named tests was made alkaline with NaOH and shaken out with ether. When a drop of concentrated HCl was added to this ethereal solution a yellow precipitate was formed. This was filtered out and found to be soluble in water. The ether solution was allowed to

evaporate spontaneously, the residue mixed with a few cc. of water, filtered, acidulated with HCl and this solution tested with the same reagents. Very heavy precipitates were obtained in all cases.

The total quantity of acidulated aqueous solution was then treated with potassium bismuth iodide. A very heavy deep red precipitate was obtained. This was filtered out, washed with distilled water, mixed with distilled water, acidulated with HCl and  $\text{H}_2\text{S}$  passed through the mixture, the bismuth sulphide filtered off, the filtrate made alkaline with KOH and shaken out with ether and the ether allowed to evaporate spontaneously, leaving a yellow amorphous residue.

Some of this residue, dissolved in water and acidulated gave precipitates with all the reagents named above.

The amount of this residue was not sufficient for further examination.

### CANNABIS SATIVA:

IS THE MEDICINAL VALUE FOUND ONLY IN THE INDIAN GROWN DRUG?

---

H. C. HAMILTON, M. S.

---

Not many students of the subject will to-day answer this question in the affirmative. There is too much evidence to the contrary. Some, however, have not yet been brought to the point of accepting as "Standard," an extract of Cannabis Sativa irrespective of the locality from which the crude drug was obtained if the fact is noted that it is not of Indian origin. For this undoubtedly, tradition is largely responsible. Originally only three or four provinces<sup>1</sup> on the west coast of India were included in the territory from which official, medicinally active hemp could be obtained. Later,<sup>2</sup> however, no limit was placed on the drug specifications except that it be from India; and as no distinguishing feature is present to assure its origin as being Indian, no doubt much material appears on the market from other sources and is accepted as "Indian."

This statement might be accepted as the cause for the uncertain action of the drug noted by many observers. What seems much more likely to be the reason for the inconstant and inconsistent results reported by some observers, is that the variable effects, both clinical and pharmacological, which are obtainable even with active material had not, at that time, been sufficiently recognized. Houghton<sup>3</sup>.

While the dog is generally accepted as the most satisfactory test animal,<sup>1, 4 & 5</sup> not every one is applicable for the purpose. Many of them must be rejected as not being sufficiently susceptible and even the susceptible ones are not uniformly so.

This being true, unless exceptional care is exercised in observing the pharmacological action of the drug extract, misleading reports are certain to follow.

It is not the intention of the writer at this time, to adduce data to prove the activity of American grown Cannabis Sativa, because it is possible to prove almost anything one wants to prove about the activity or inactivity of extracts of

hemp. The intention is rather to point out the possible reasons for such contradictory reports as have been published. These, on the other hand, are the result of incomplete or inaccurate observation, non-susceptibility of the test animal or patient, use of an extract whose activity had been destroyed or the use of extracts from inert or only slightly active drugs. On the other hand, not infrequently a patient or a test animal is highly susceptible and a particular sample of only average quality is reputed to possess exceptional activity. Many statements regarding the activity of hemp extracts are apparently colored by tradition, it being concluded without further comment that only the Indian grown drug contains the narcotic principle. Cushny<sup>6</sup> states that *Cannabis Sativa* is of pharmacological interest only when grown in warm climates including Southern United States. Kobert<sup>7</sup> claims that the official preparations have no action on animals and that their action on humans is inconstant. Fraenkel<sup>1</sup> says: "The action of haschisch differs greatly according to climate, race and individuality." Bibra's book<sup>8</sup> contains very interesting descriptions of experiments with haschisch on humans which proved its strongly differing action on the individual. Sollmann<sup>9</sup> says: "Hemp grown in western countries is generally devoid of *Cannabinol* and is inactive." Wood, (Geo. B.)<sup>10</sup> noted that the European hemp appeared to have none of the exudate typical of the Indian grown drug and of that growing in the vicinity of Philadelphia. If this last statement is true, it is a logical explanation of European opinion that only the drug from India contains appreciable activity. It is probably true only in exceptional cases. Wood (H. C.)<sup>10</sup> found that less than 1 gr. of an alcoholic extract of Kentucky grown hemp was effective on himself. This would apparently indicate exceptional activity since 1 gram of Ext. *Cannabis Indica* will not ordinarily produce so intense an action as that described. Actually, it would seem probable that he is occasionally, or generally, more susceptible than the average person.

The most recent reference of note is that by Eckler & Miller<sup>5</sup> in which several series of experiments were carried out, all leading to the conclusion "that if American *Cannabis* is made official, difficulty will generally be experienced in obtaining highly active lots which will compare favorably with a good Indian drug." One statement in their summary is that "very little dependence can be placed on the estimation of the extractive matter yielded to alcohol." This, in the writer's experience, is too general a statement. The Extract is rarely inactive. When an Extract is entirely soluble in cold 95% ethyl alcohol, the yield is a fair indication of the activity of the drug<sup>11</sup>. There are exceptions to this statement, however, so that it cannot be taken as true in any particular case without being verified by pharmacological assay but it may be taken as roughly indicating the value, other things being equal.

The Powdered Extract *Cannabis Sativa*, from whatever source the drug originated, very readily deteriorates. In fact, one lot came under the writer's observation in which no activity could be detected, while the extract from which it was made was of full standard activity, i. e., 10 mg. per kilo administered to a susceptible dog elicited the in-coördination characteristic of the drug's action.<sup>11</sup> Undoubtedly, a similar deterioration may take place in the drug or in an extract without any recognizable change in its physical properties.

Exception may also be taken to the experiments of Eckler and Miller on account of the quality of the drug used. In no case was the quality of the crude drug, at all comparable to the quality of the Indian Cannabis with which its activity was compared. A sample of crude drug containing a large proportion of seeds, stems, and leaves, this being the description applying to most of the samples they tested, is very different from the average quality of Indian drug imported, and one should not expect equality either in yield or activity. Much better drug should be and is available on the market.

The writer<sup>11</sup> has carried out tests for the activity of samples of drug grown personally from seed collected from Indian drug, and invariably found no activity in either the stems or seed. The leaves, however, when gathered before any brown color due to decay was evident, were found to contain almost as much extractive with almost the same activity as the imported drug which meets U. S. P. requirements, while the flowering tops of the pistillate plant—the part corresponding exactly to the requirements for Indian Cannabis—were found fully equal and in some cases superior to the average good quality imported drug meeting U. S. P. requirements. This and other equally favorable results, were reported in former papers.

There are occasional samples of American drug decidedly less active than standard both as regards yield of extract and its activity. These, however, can be paralleled by samples of Indian drug having no greater activity.

With the exercise of caution in selecting the drug and insistence on certain qualities essential to drug of good quality, American producers can supply material practically of equal value to that imported. It will be necessary, however, for manufacturers of extracts of this drug to recognize the economic difficulties that stand in the way of duplicating the physical qualities of the imported drug. Hand-picking is out of the question and almost of necessity the commercial drug will contain leaves, stems and seeds with some admixture of the male plant.

To obviate the difficulty of so specifying as to exclude undesirable parts, it seems advisable to specify merely as regards yield and activity of extract from the botanically correct drug. Then, no sample of hemp plant that can be economically extracted and that yields an active extract, need be rejected because of physical difference from rigid U. S. P. specifications. If the extract is active and if the yield and the cost of the drug are compensatory we then have an economic condition that should be satisfactory.

Also as Scoville<sup>12</sup> has pointed out, the crude drug is not used as such and really requires no specifications except botanical.

Another question has been raised relative to the comparability of therapeutic and pharmacologic activity. This point was raised by Dr. Rusby and was answered in a paper presented before this section two years ago.<sup>13</sup> Experiments indicated that the dog, under rigidly prescribed conditions, is a satisfactory test animal and that lack of therapeutic results from pharmacologically active samples may safely be ascribed to individual variability. Schroof,<sup>14</sup> moreover, has pointed out that non-susceptibility is not absolute but is merely a question of quantity.

We conclude, therefore, that, first, American hemp contains the active constituent; second, if equal care is exercised in selecting the proper part of the drug for extraction, no material difference in activity will be found between extracts of Indian and American hemp; third, apparent lack of activity and variability in

activity applies equally to both varieties of this drug; fourth, under proper direction there is no valid reason why American hemp cannot be collected to advantage to replace the imported article.

## ESTIMATION OF YELLOW PHOSPHORUS.

H. ENGELHARDT AND O. E. WINTERS.

At the Nashville meeting of the American Pharmaceutical Association we presented a paper on the estimation of Yellow Phosphorus. This paper was offered by us only as a preliminary one. Since then we have made numerous experiments in regard to the estimation of the metalloid and on the strength of these are now compelled in some instances to offer slightly modified methods. Since the paper did not appear in the Journal of the American Pharmaceutical Association up to May, 1914, we requested that the paper be not published prior to the meeting of the Association at Detroit when we would be in a position to give more details of the various methods applied by us in addition to a number of results obtained with pharmaceutic products of various kinds.

For the estimation of phosphorus several methods have been published. The distillation process for estimating phosphorus originated by Mitcherlich and later on modified by Dusart and Blondlot can be applied only when comparatively small quantities of phosphorus are present because the metalloid is not as volatile with steam as is generally accepted. It requires hours to distill as little as 50 mgms. of phosphorus. Neither the oxidation of the phosphorus in the distillate with nitric acid or bromine as carried out in Mitcherlich's method, nor the conversion of the phosphorus into silver phosphide and subsequent oxidation of the latter to phosphoric acid yield satisfactory results.

Various processes depending on the oxidation of phosphorus with nitric acid and simultaneously destroying any organic matter present, by this acid, by concentrated sulphuric acid or other chemicals were therefore recommended by Sayda,<sup>1</sup> Fry,<sup>2</sup> Vanderkleed and Turner,<sup>3</sup> Woerner<sup>4</sup> and others. These processes, however, have the disadvantage in that by them the total and not the elementary phosphorus alone is determined.

Reed<sup>5</sup> determined the phosphorus by allowing a solution of bromine in acetone,

previously standardized against phosphorus, to act on the phosphorus solution, until a faint but persistent yellow color was produced.

Most of the methods for estimating phosphorus depend on the property of phosphorus of forming insoluble phosphides with some of the heavy metals, especially silver and copper, which can easily be oxidized to phosphorous and phosphoric acid respectively.

The methods originated by Tothe,<sup>6</sup> Louise,<sup>7</sup> Stich,<sup>8</sup> Fränkel,<sup>9</sup> and Illes<sup>10</sup> depend on the conversion of a solution of the phosphorus in a convenient solvent (in most cases acetone) into silver phosphide and estimating the latter as such or by oxidation into phosphoric acid.

The property of the copper salts to convert phosphorus into non-poisonous phosphide and finally into phosphoric acid has been known for years, and copper salts therefore have been used with advantage as an antidote in cases of phosphorus poisoning. The first one to use copper salts for estimating phosphorus was Straub<sup>11</sup> whose method was later modified by Katz,<sup>12</sup> who recommends using copper nitrate instead of copper sulphate for converting the phosphorus into phosphide, by Christimanos<sup>13</sup>, Korte<sup>14</sup>, Tauchert<sup>15</sup> and others. All these investigators found that by the action of copper sulphate on phosphorus, phosphoric acid, sulphuric acid, copper phosphide and metallic copper are formed though they were not able to establish a definite equation for this reaction.

Finally Enell's method must be mentioned. This process which is exceptionally suitable for the estimation of phosphorus in phosphoretted oil depends on the oxidation of phosphorus by standardized iodine solution, titrating back the excess of the latter with thiosulphate solution then estimating alkalimetrically the amount of phosphoric acid formed by the oxidation and deducting from this the amount of acid originally present in the oil.

For estimating the phosphorus in commercial yellow phosphorus and in galenical preparations we have applied both Louise's silver method as modified by Fränkel and Straub's copper method with Katz's modification.

*Yellow Phosphorus*.—The phosphorus was carefully deprived of any oxidation products by scraping, then dried in an atmosphere of carbonic acid and weighed. It was then dissolved in chloroform free from air and the solution was made up with chloroform to a certain volume.

10 cc. of the solution corresponding to .03656 gm. of phosphorus was mixed in a bottle with 15 cc. of 10 *per cent.* copper nitrate solution from which the air previously had been expelled by heating. The air in the bottle was replaced by carbonic acid gas and the mixture shaken for about one-quarter hour. Hydrogen peroxide was then added and the mixture shaken again until the black color of the copper phosphide had disappeared. The aqueous solution was separated from the

chloroformic solution, the latter washed out twice with about 15 cc. of water and the combined aqueous solutions and wash-waters after the addition of nitric acid were evaporated to about 5 cc. testing from time to time for unoxidized phosphorous acid. When oxidation was complete the phosphoric acid was estimated in the aqueous liquid as magnesium pyrophosphate. Should any copper salt separate together with the ammonium magnesium phosphate, the latter is re-dissolved and re-precipitated.

In this way we obtained magnesium pyrophosphate corresponding to 101.5 *per cent.* of the phosphorus taken for the estimation. In order to find out whether the phosphorus contained any appreciable amount of oxidation products, the chloroformic solution of the phosphorus was shaken out with various quantities of carbonated water but the amount of magnesium pyrophosphate obtained from the aqueous solution and calculated for phosphorus, showed the phosphorus to have a purity of 99.2 *per cent.* In other words, only traces of oxidation products were present in the phosphorus used for this test.

In another series of experiments 15 cc. of a solution of phosphorus in chloroform containing .1064 gm. of phosphorus were treated in the same way, and the results obtained, calculated for phosphorus, were 100.5, 98.7, 99.8 and 100.0 *per cent.*

When substituting the copper nitrate by silver nitrate and filtering the silver phosphide, we obtained in the first experiments magnesium pyrophosphate corresponding to only 78.6, 77.1, 81.6 and 82.4 *per cent.* of the amount of phosphorus used. This amount was not materially decreased by previously washing the chloroformic solution with water. The results were 78.6, 80.9 and 79 *per cent.* The estimation was carried out by mixing the chloroformic phosphorus solution in a bottle filled with carbonic acid gas with about 10 cc. of a 50 *per cent.* silver nitrate solution, shaking the mixture for about one-half hour, and, after allowing to settle, collecting the silver phosphide in a Gooch crucible. The silver phosphide was then oxidized with 25 *per cent.* nitric acid and in the resulting solution the silver was removed by hydrochloric acid. The mixture was filtered again, the filtrate evaporated to dryness, the residue taken up in water and the phosphoric acid precipitated in the regular way.

The discrepancies in the results obtained by the copper nitrate method and the silver nitrate method were probably due to the fact that on adding to a solution of phosphorus in chloroform, silver nitrate or copper nitrate, some oxidation products of nitrogen are formed in addition to the respective phosphides, which in turn dissolve any metallic phosphide formed or inhibit the formation of the phosphide to some extent.\*

In order to prove this, 15 cc. of the chloroformic phosphorus solution, containing .1064 gm. of phosphorus, were treated in an atmosphere of carbonic acid gas with copper nitrate, the mixture was shaken for one-half hour and after settling, the copper phosphide was collected in a Gooch crucible. It was oxidized with hydrogen peroxide solution with the addition of traces of nitric acid, and the solution was evaporated to dryness on a water-bath after the addition of more

\* According to Bird and Diggs (Journ. Amer. Chem. Soc., 1914, page 1383), nitric acid is formed when converting the phosphorus into phosphides with copper nitrate or silver nitrate. They also found that nitric acid even when very diluted acts on the phosphorus.

nitric acid in order to convert all the lower oxidation products of phosphorus into phosphoric acid. The residue was then taken up with water and the phosphoric acid estimated in the usual way. By this method we obtained .224, .231 gm. of magnesium pyrophosphate. The filtrate from the copper phosphide was oxidized in the regular way by evaporation in the presence of nitric acid, the residue taken up in water and the phosphoric acid determined as magnesium pyrophosphate: .161, and .153 gm. of magnesium pyrophosphate were obtained. The combined magnesium pyrophosphate obtained from the precipitate and the filtrate therefore was .385 and .384 gm. respectively, corresponding to 100.7 and 100.6 *per cent.* of phosphorus. In another experiment 15 cc. of the phosphorus solution were treated with silver nitrate solution, the silver phosphide was collected in a Gooch crucible, oxidized with nitric acid, etc. The following results were obtained: .307, .303, .305, .308 gm. of magnesium pyrophosphate. In the filtrate .065, .064, .069, .064 gm. of magnesium pyrophosphate was found. This gives a total .372, .371, .374, .372 gm. respectively of magnesium pyrophosphate, corresponding to 97.9, 97.6, 98.1, 97.6 *per cent.* of phosphorus.

These experiments show that the phosphorus cannot be estimated by collecting the copper phosphide or silver phosphide on a filter, because in the reaction some substances are formed which dissolve a part of the phosphide already formed or convert the phosphorus into oxidation products which naturally do not form phosphides.

For the estimation of phosphorus in a solution in chloroform or any other suitable solvent, the copper nitrate method therefore is to be preferred, because the mixture of copper phosphide, copper nitrate, water, chloroform, etc., can be treated directly with hydrogen peroxide solution, while in the silver nitrate method the silver phosphide cannot be well oxidized with nitric acid in the presence of chloroform. In the silver method the silver phosphide is preferably collected in a Gooch crucible and in the filtrate the oxidation products are to be estimated separately thus involving two manipulations instead of one as in the copper method. In our previous paper we expressed the opinion that copper phosphide is more stable than silver phosphide. This, however, is not the case as has developed in the course of later experiments.

*Phosphorus Resin:* In our previous paper we reported that for estimating the phosphorus in phosphorus resin we applied the following methods to a sample which was several years old and reputed to have contained originally 10 *per cent* of phosphorus. About 4 gms. of the resin (accurately weighed) were dissolved in 50 cc. of air-free chloroform in a separator, 20 cc. of air-free water were added, the air in the separator replaced by carbonic acid gas and the mixtures shaken for one-quarter hour. An aliquot part of the chloroformic solution was then drawn off and treated with copper nitrate solution as given above. The resin was found to contain 7.33 and 7.45 *per cent* respectively of phosphorus, thus showing that about 25 *per cent* of the latter had been lost either by volatilization or oxidation.

Since then we have made quite a number of experiments in regard to estimating the phosphorus in phosphorus resin, especially for the purpose of finding out whether or not the ammonium magnesium phosphate is free from magnesium

abietate and also to what extent phosphoric acid is formed when treating the copper phosphide with hydrogen peroxide solution only.

The resin used for these experiments was dried over sulphuric acid in an atmosphere of carbonic acid gas for one week. One gramme was dissolved in 50 cc. of air-free chloroform, the solution was shaken out with various small portions of water in order to remove any oxidation products, and was then shaken well for one-half hour with 10 cc. of a 10 *per cent* copper nitrate solution. After the addition of an excess of hydrogen peroxide solution the mixture was shaken again until the copper phosphide had been oxidized, i. e., until the black color of the latter had disappeared. The aqueous solution was then separated in the usual way, mixed with nitric acid and evaporated to dryness. The residue was taken up in water with the addition of hydrochloric acid and the phosphoric acid precipitated with magnesia mixture.

By this process the following results were obtained:—

.224 gm. of  $Mg_2P_2O_7$  = 6.25 *per cent.* of phosphorus  
 .219 gm. of  $Mg_2P_2O_7$  = 6.13 *per cent.* of phosphorus  
 .224 gm. of  $Mg_2P_2O_7$  = 6.25 *per cent.* of phosphorus  
 .225 gm. of  $Mg_2P_2O_7$  = 6.26 *per cent.* of phosphorus

In the next series of experiments the copper phosphide was treated in the same way, the phosphoric acid precipitated with ammonium molybdate solution, the ammonium phospho-molybdate dissolved in ammonia water and the phosphoric acid again precipitated with magnesia mixture. We then obtained:—

0.225 gm. of  $Mg_2P_2O_7$  = 6.26 *per cent.* of phosphorus  
 0.220 gm. of  $Mg_2P_2O_7$  = 6.15 *per cent.* of phosphorus

In still another series of experiments, the phosphoric acid obtained by oxidizing the copper phosphide and further oxidizing the resulting solution with nitric acid was precipitated with magnesia mixture, the ammonium magnesium phosphate was dissolved in hydrochloric acid, and this solution was shaken out with ether to remove any abietic acid. The phosphoric acid was then precipitated with magnesia mixture. This yielded:—

.227 gm. of  $Mg_2P_2O_7$  = 6.34 *per cent.* of phosphorus  
 .224 gm. of  $Mg_2P_2O_7$  = 6.25 *per cent.* of phosphorus

These results clearly show that in precipitating the aqueous solution with magnesia mixture no magnesium abietate is carried down with the ammonium magnesium phosphate.

That by oxidizing the copper phosphide with hydrogen peroxide solution alone, only a part of the phosphorus is oxidized to phosphoric acid is shown by the following experiment:—

One gramme of the above resin was treated as given before and the aqueous solution obtained after decomposing the copper phosphide with hydrogen peroxide solution was precipitated with magnesia mixture.

.140 gm. of  $Mg_2P_2O_7$  = 3.92 *per cent.* of phosphorus  
 .140 gm. of  $Mg_2P_2O_7$  = 3.92 *per cent.* of phosphorus  
 .143 gm. of  $Mg_2P_2O_7$  = 4.05 *per cent.* of phosphorus

were obtained, thus showing that only 50 *per cent.* of the copper phosphide had been oxidized to phosphoric acid. It is, therefore, absolutely necessary to oxidize the aqueous liquid containing the oxidation products of the phosphorus with a strong oxidizing agent, preferably nitric acid.

When applying the silver method to the resin only

.153 gm. of  $Mg_2P_2O_7$  = 4.27 *per cent.* of yellow phosphorus  
 .153 gm. of  $Mg_2P_2O_7$  = 4.27 *per cent.* of yellow phosphorus  
 .148 gm. of  $Mg_2P_2O_7$  = 4.14 *per cent.* of yellow phosphorus

were obtained, or only about 65 *per cent.* of the amount obtained by the copper method. With another old resin the following figures were obtained:—

Copper method 5.57 <i>per cent.</i>	Silver method 3.88 <i>per cent.</i>
5.85 <i>per cent.</i>	3.82 <i>per cent.</i>
5.85 <i>per cent.</i>	4.02 <i>per cent.</i>

thus again showing that by the silver method only about two-thirds of the phosphorus as found by the copper method is obtained.

For estimating the oxidation products present in the resin, the following experiments were made with a preparation containing

7.33 *per cent.* of phosphorus; 7.45 *per cent.* of phosphorus

when assayed by the copper nitrate method.

4 gms. of resin were dissolved in 50 cc. of air-free chloroform and the solution was shaken out in a separator filled with carbonic acid gas with several portions of air-free water. The chloroformic solution was transferred to a 100 cc. graduated flask and the volume of the liquid was made up with air-free chloroform to the mark. In aliquot parts of the chloroformic solution the phosphorus was determined by the copper nitrate method directly, without separating the copper phosphide. The aqueous solution after expelling any dissolved carbonic acid by heating was titrated with N 10 caustic potash solution of which 51.3 cc. 50.4 cc. were required for neutralization, using phenolphthalein as indicator. This amount corresponds to 12.8 and 12.6 cc. respectively for one gramme of resin. In another series of experiments only 2 gms. of resin were used for the estimation, when 26.6 and 26.0 cc. of N 10 KOH were used, corresponding to 13.3 and 13.0 cc. for one gramme of resin. Since the alkali is used for the various oxidation products of the phosphorus, it was impossible to calculate the amount of phosphorus present as oxidation products from the amount of alkali used in the titration. The aqueous liquids were therefore evaporated after the addition of nitric acid and in the residue the phosphoric acid was estimated as magnesium pyrophosphate. Thus the following results were obtained:—

Experiment I. (4 grams.)	.281 gm. of $Mg_2P_2O_7$	
	.288 gm. of $Mg_2P_2O_7$	
corresponding to	.07024 gm. of $Mg_2P_2O_7$	in one gm. of resin or to
	.072 gm. of $Mg_2P_2O_7$	
	1.96 <i>per cent.</i> of phosphorus	
	2.03 <i>per cent.</i> of phosphorus	
Experiment II. (2 grams.)	.146 gm. of $Mg_2P_2O_7$	
corresponding to	.149 gm. of $Mg_2P_2O_7$	
	.073 gm. of $Mg_2P_2O_7$	
	.0745 gm. of $Mg_2P_2O_7$ or to	
	2.04 <i>per cent.</i> of phosphorus	
	2.065 <i>per cent.</i> of phosphorus	

These experiments show that the direct copper method can be used for estimating the percentage of elementary phosphorus in phosphorus resin. They also show that it is quite easy to estimate the amount of oxidation products of phosphorus present in the preparation.

*Phosphorus Paste*.—For phosphorus paste such as is used for making pills the following method was applied. About one gramme of the paste, exactly weighed, was mixed in a bottle filled with carbonic acid gas, with 25 cc. of air-free chloroform and 25 cc. of air-free water and the mixture shaken for fifteen minutes. After allowing the mixture to separate, the aqueous layer was siphoned off, and the chloroform was shaken once more with 15 cc. of air-free water to remove the last traces of oxidation products of phosphorus. The water was again separated from the chloroformic solution and the latter was treated with copper nitrate and silver nitrate respectively and the estimation carried out as outlined above.

In a paste supposed to contain 7 *per cent.* of phosphorus, 6.86 and 6.7 *per cent.* were found by the copper method. By the silver method, only 5.78 and 5.86 *per cent.* of phosphorus were found. The above method applied for the estimation of phosphorus in another paste supposed to contain 10 *per cent.* of phosphorus was modified in that the aqueous solution after separating was shaken out with two portions of 25 cc. each of chloroform in order to remove any phosphorus suspended in the liquid. The combined chloroformic liquids were then treated in the regular way with copper nitrate solution. Thus 9.29 and 9.64 *per cent.* of phosphorus were obtained, by the silver method only 7.19 and 7.24 *per cent.*

*Spirit of Phosphorus*.—The N. F. directs that spirit of phosphorus be made by boiling 1.2 gms. of phosphorus with 1000 cc. of absolute alcohol until solution has taken place, and after cooling replacing any alcohol lost by evaporation. No requirements are given for the finished spirit, and it is probably understood that the spirit contain about 0.1 *per cent.* of phosphorus. In our previous paper we reported that we had been unable to prepare a spirit containing even approximately the amount of phosphorus required and we ascribed this shortage to oxidation of the phosphorus taking place during the boiling.

The method which we applied at that time was the following:—25 cc. of the spirit were transferred to a separator, mixed with air-free copper nitrate solution and the air in the separator replaced by carbonic acid gas. The mixture was then shaken well for a short time and allowed to stand until complete separation of the copper phosphide had taken place. The latter was collected on a filter in an atmosphere of carbonic acid gas, washed with a little air-free copper nitrate solution, decomposed by hydrogen peroxide solution preferably with the addition of a few drops of nitric acid, the solution evaporated in the presence of nitric acid to about 5 cc. and the phosphoric acid estimated as magnesium pyrophosphate. In the filtrate from the copper phosphide the oxidation products present in the spirit were estimated in the regular way. We thus obtained the following results with a spirit which was prepared by boiling phosphorus in excess with absolute alcohol for 12 hours and preserving the spirit in a bottle filled with carbonic acid gas:

<i>Phosphorus converted into copper phosphide.</i>	<i>Phosphorus present as oxidation products in filtrate from copper phosphide.</i>
0.068 <i>per cent.</i>	0.123 <i>per cent.</i>
0.073 <i>per cent.</i>	0.116 <i>per cent.</i>
0.0678 <i>per cent.</i>	
0.0704 <i>per cent.</i>	
0.069 <i>per cent.</i>	
0.0708 <i>per cent.</i>	

At that time we made a number of experiments by precipitating the phosphorus from the spirit in the presence of varying amounts of alcohol and water, and since

we found that the strength of the alcohol did not have any material influence on the yield of copper phosphide we concluded that the phosphorus was precipitated quantitatively as phosphide. However, we did not take into consideration the amount of phosphorus not converted into phosphide, nor the amount of phosphide redissolved by the oxidation products of nitrogen which are formed in the reaction.

Since then (see results below) we have found that in making spirit of phosphorus only about 10 *per cent.* of the phosphorus is converted into oxidation products during the boiling process. The above spirit therefore contained

0.172 *per cent.*

0.170 *per cent.*

of phosphorus instead of about 0.07 *per cent.* as reported at that time.

After numerous experiments we finally found the following method to be quite reliable for estimating the yellow phosphorus in the spirit:—

25 cc. of the spirit (prepared by boiling an excess of phosphorus with ordinary alcohol) was mixed with 50 cc. of air-free chloroform and 50 cc. of water. The mixture was shaken well and when complete separation had taken place the chloroformic solution was drawn into a flask filled with carbonic acid gas. The aqueous liquid was shaken out with two more portions of 25 cc. each of chloroform in order to remove any phosphorus suspended in the aqueous solution and the combined chloroformic liquids were then treated with copper nitrate in the usual way. The copper phosphide mixture was oxidized with  $\text{H}_2\text{O}_2$  and the phosphoric acid estimated in the usual way. In the aqueous liquid obtained by shaking out the diluted spirit with water, the oxidation products of phosphorus were estimated. We thus obtained the following results:—

Phosphorus as such in the Spirit  
 .133 gm.  $\text{Mg}_2\text{P}_2\text{O}_7$  = .119 *per cent.*  
 .137 gm.  $\text{Mg}_2\text{P}_2\text{O}_7$  = .133 *per cent.*

Oxidation Products,  
 0.0123 *per cent.*  
 0.0121 *per cent.*

In another series of experiments the spirit diluted with water was shaken out with chloroform, the chloroformic solution was treated with copper nitrate, the copper phosphide separated by filtration in an atmosphere of carbonic acid gas and the phosphorus estimated both in the precipitate and filtrate. We obtained

Phosphorus from precipitate,  
 0.071 gm.  $\text{Mg}_2\text{P}_2\text{O}_7$  = 0.0795 *per cent.*  
 0.071 gm.  $\text{Mg}_2\text{P}_2\text{O}_7$  = 0.0795 *per cent.*

Phosphorus from filtrate,  
 0.062 gm.  $\text{Mg}_2\text{P}_2\text{O}_7$  0.0693 *per cent.*  
 0.066 gm.  $\text{Mg}_2\text{P}_2\text{O}_7$  0.0715 *per cent.*

Replacing copper nitrate by silver nitrate, filtering the silver phosphide, etc., we obtained:—

Phosphorus from precipitate,  
 102 gm.  $\text{Mg}_2\text{P}_2\text{O}_7$  = .111 *per cent.*  
 100 gm.  $\text{Mg}_2\text{P}_2\text{O}_7$  = .116 *per cent.*

Phosphorus from filtrate,  
 0.026 gms.  $\text{Mg}_2\text{P}_2\text{O}_7$  0.0297 *per cent.*  
 0.026 gms.  $\text{Mg}_2\text{P}_2\text{O}_7$  0.0291 *per cent.*

These results clearly show that copper phosphide is more soluble than silver phosphide in the oxidation products of nitrogen formed by the action of copper nitrate on a chloroformic solution of phosphorus in the presence of alcohol.

We have made a series of experiments with the purpose in view to reduce the amount of soluble phosphorus compounds by filtering the silver phosphide in an atmosphere of carbonic acid gas, but this seems to have no influence whatever on the results. In our previous paper we pointed out that the spirit of phosphorus is a rather unstable preparation even when kept in an atmosphere of carbonic acid, and this statement has been verified by recent experiments.

A spirit assaying at the time of manufacture .137 *per cent.* assayed, after one week's standing, only 0.117 *per cent.* and the oxidation products, calculated as phosphorus, had increased from 0.0123 *per cent.* to 0.0313 *per cent.* After three week's standing the percentage of phosphorus had been decreased to 0.088 *per cent.* A spirit prepared under exactly the same conditions, which, however, was not assayed at the time of manufacture, showed after four months standing only 0.0415 *per cent.* of yellow phosphorus and 0.087 *per cent.* of phosphorus present as oxidation products.

Only freshly prepared spirit of phosphorus should therefore be used.

*Phosphorus Pills:*—The process applied for assaying phosphorus pills and tablets both of plain and complex composition, is almost identical with that given for the assay of phosphorus paste.

A quantity of pills equivalent to about one grain of phosphorus is mixed in a bottle with 25 cc. of air-free water and 100 cc. of air-free chloroform. The air in the bottle is replaced by carbonic acid gas and the mixture is then shaken well until the pills are disintegrated. After allowing the liquids to separate as much as possible the aqueous layer is siphoned off. The mixture is then shaken with sufficient tragacanth to eliminate the remaining water, an aliquot part of the chloroformic solution is filtered off, treated with copper nitrate, etc.

We have examined a great number of pills and tablets and the following results may therefore be of interest:—

*Phosphorus Pills plain 1/100 gr.*

1/92, 1/92.7, 1/92, 1/93, 1/90 gr.

*Phosphorus Pills plain 1/25 gr., 1/23.4, 1/24.2, 1/25.*

*Phosphorus Pills plain 1/50 gr.*

1/48, 1/45, 1/46.5 1/46.2 gr.

Pills claimed to contain 1/30 gr. of phosphorus in addition to extract of damiana and extract of nux vomica, were found to contain 1/30 gr. and 1/31 gr. of phosphorus respectively.

Four lots of Aphrodisiac pills which contained, in addition to 1/100 gr. of phosphorus, extract of damiana and extract of nux vomica assayed 1/102 gr., 1/112, 1/98, 1/101 gr.

Another kind of Aphrodisiac pills which contained, in addition to the above ingredients, powdered muirapuama were found to contain 1/93 and 1/94 gr. of phosphorus instead of 1/100 gr. claimed on the label.

Pills coated with sugar, showed that no loss of phosphorus is entailed in the coating process as shown by the assay of four lots of Aphrodisiac pills which assayed, instead of 1/100 gr. of phosphorus, 1/102, 1/98, 1/101 and 1/102 gr.

All these assays were carried out with the copper method without filtering the copper phosphide. These results were obtained with freshly-made pills. In the manufacture of these pills an excess of 10 *per cent.* of phosphorus had been added to the pill mass in order to meet any loss of phosphorus by volatilization and oxidation.

That, however, phosphorus pills are not absolutely stable may be shown by the following results:—Plain phosphorus pills which were one year old showed only 86.2 *per cent.* of the amount of phosphorus claimed on the label; pills containing 1/50 gr. after one and one-half years showed only 83.5 *per cent.*; one year old 1/100 gr. pills assayed 76 *per cent.*; nine months old 1/150 gr. pills only 79 *per*

*cent.* These results seem to show that the greater the dilution of the phosphorus in the pill mass the greater the loss of phosphorus.

While the loss of the metalloid is not very great in plain pills it is quite marked in complex pills. Aphrodisiac pills which were one year old and which contained 1/100 gr. of phosphorus, in addition to extract of nux vomica and extract of damiana, contained after one year only 42 *per cent.* of the phosphorus present.

In a lot of Aphrodisiac pills one year old, which contained nux vomica and damiana with 1/100 gr. of phosphorus, only 57 *per cent.* of the phosphorus was found.

A lot of the same kind of pills 11 years old showed only 16 *per cent.* of the phosphorus as claimed on the label.

Pills containing in addition to 1/100 gr. of phosphorus, 1/4 gr. of extract of nux vomica, showed after three years 46.5 *per cent.* Pills containing in addition to 1/50 gr. phosphorus, 1/4 gr. of extract of nux vomica, showed after one and one-half years 42.5 *per cent.* of phosphorus, while other pills which contained in addition to 1/50 gr. of phosphorus, 1/8 gr. of extract of nux vomica, after the expiration of three years still showed 75 *per cent.* of phosphorus.

Pills containing 1/50 gr. of phosphorus in addition to 1 gr. powdered cantharides and 1 gr. of powdered nux vomica, showed after two years 68.5 *per cent.* of the amount of phosphorus originally present.

Phosphorus, Quinine and Nux Vomica pills containing 1/50 gr. phosphorus, 1 gr. quinine sulphate and 1/4 gr. extract of nux vomica contained after one year 45 *per cent.* of phosphorus. On the other hand pills containing 1/40 gr. phosphorus, 1 gr. zinc sulphate, 2 grs. extract valerian, still showed after three years 91 *per cent.* of the phosphorus originally present.

That the presence of extracts has a greater influence on the dissipation of the phosphorus than plain ingredients such as alkaloids, etc., may be shown by the following results. Phosphorus and Strychnine pills supposed to contain 1/50 gr. phosphorus and 1/60 gr. strychnine showed after one year 89.5 *per cent.* of phosphorus; pills containing 1/100 gr. of phosphorus and 1/60 gr. of strychnine still showed after three-quarters of a year, 93 *per cent.* of the amount of phosphorus. Phosphorus, Quinine and Strychnine pills containing 1/50 gr. of phosphorus, 1 gr. quinine sulphate, 1/60 gr. strychnine, after two years still contained 85 *per cent.* of phosphorus.

As has been pointed out in our previous paper, the presence of iron salts seem to favor the dissipation of the phosphorus, because in four lots of pills containing varying amounts of iron in the form of iron carbonate or reduced iron, phosphorus was found only in very small amounts. We have again made quite a number of experiments with Aphrodisiac pills containing in addition to the other ingredients, phosphorus and iron bromide. We have tried the copper nitrate silver nitrate and copper acetate methods, but in no case have we been able to obtain trustworthy results. The phosphorus seems to act on the iron bromide and thus make the assay extremely difficult, if not impossible.

Of tablets we examined only a few lots containing extract of damiana and extract of nux vomica in addition to 1/30 gr. of phosphorus. In freshly made tablets we found 1.29, 1.31, 1.28, 1.33 gr. of phosphorus. On reassaying the tablets after 1, 2, 4 and 6 months we found the amount of phosphorus originally

present in the tablets had decreased considerably. This seems to show that the phosphorus keeps better in pill mass than in tablet mass and also better in coated than in uncoated pills.

*Elixir of Phosphorus*.—In our previous paper we reported that we had applied the following process for estimating yellow phosphorus in elixirs of phosphorus, especially in those which are largely used as aphrodisiacs, such as Elixir Phosphorus, Nux Vomica and Damiana.

25 cc. of the elixir under examination are mixed with 100 cc. of air-free chloroform in a 150 cc. bottle, the air in the bottle is replaced by carbonic acid gas and the mixture is shaken well for one-quarter hour. An aliquot part of the chloroformic solution (taking into consideration the amount of alcohol present in the preparation) is then separated, shaken with copper nitrate and the assay is then finished in the usual way. We reported at that time that elixirs of this kind made with freshly-prepared spirit of phosphorus do not retain the phosphorus for any length of time. This could be proven not only by assaying the elixir according to the copper method, but also by applying Mitcherlich's test.

Quite recently we have modified the method in the following way:—25 cc. of the elixir is mixed with 50 cc. of air-free water in a separator, the air in the separator is replaced by carbonic acid gas and the mixture is shaken out with 50, 25 and 25 cc. of air-free chloroform. By this process the alcohol present in the elixir does not need to be taken into consideration. The combined chloroformic liquids were then shaken out once with 10 cc. of air-free water in order to remove any oxidation products of the phosphorus suspended in the chloroformic solution, and the latter was then treated with copper nitrate in the regular way. An elixir which contained in addition to the other ingredients 24.40 *per cent.* of spirit of phosphorus, yielded when assayed by the copper method only 0.0198 *per cent.* of phosphorus. The spirit used for making this elixir assayed .09 *per cent.* of elementary phosphorus. After three weeks standing in an ice-chest the percentage of phosphorus had been reduced to 0.0179 *per cent.*, thus showing a loss of about 10 *per cent.* It is rather difficult to estimate the amount of phosphorus in the regular Elixir Phosphorus, Nux Vomica and Damiana which contains only about 6 *per cent.* of spirit of phosphorus. We have made a great number of experiments with various lots of this elixir, but the results obtained, although agreeing very well when made with the same lot of elixir, varied considerably from those obtained with other lots of the elixir. This is probably due to the presence of traces of phosphates in the various ingredients used for manufacturing the elixir, which, considering the small amount of phosphorus present in the preparation, are liable to upset the results considerably.

Having found that a reliable method is available for estimating phosphorus in most pharmaceutical preparations, we expect to determine the rate of deterioration of such products. We shall also apply other copper salts, copper sulphate, acetate, chloride, etc., for converting the phosphorus into phosphide, and we hope to be able to report on these experiments at the next meeting of the Association.

Papers Presented at the Sixty-Second Annual Convention

### PHARMACEUTICAL EDUCATION.

FRANK R. ELDRED.

Pharmaceutical Education is a very comprehensive title, and it will, perhaps, be well at the outset to state that the present discussion refers only to the training in the United States for certain branches of pharmaceutical work.

The consideration of pharmaceutical education is usually limited to the educational requirements of retail pharmacy, but it must be remembered that the requirements of modern pharmaceutical manufacturing and drug inspection are quite different. Students frequently seek advice in regard to the course of study which should be pursued to fit them for positions as drug chemists; and directors of schools of pharmacy, chemistry, and chemical engineering occasionally ask the same question. The answer is usually unsatisfactory, for this branch of pharmaceutical education has received very little attention. Teachers have frequently had experience as retail pharmacists, but rarely as manufacturers or drug inspectors, therefore, they cannot know the requirements for such positions from personal experience, and it remains for official and industrial drug chemists to indicate the character of training required. The writer believes that this should be essentially the same for chemists who engage in drug inspection and manufacturing, and it is hoped that this discussion will lead to the consideration of this field by those engaged in educational work.

The first thing to establish, is the demand for such specially-trained men, but this seems evident since the federal government and all the states require drug chemists, and every pharmaceutical manufacturer requires from one to fifteen or twenty such chemists. The conditions which exist in different manufacturing establishments vary widely; in the small factory all of the scientific work may devolve upon one man and in such cases he must have a broad and varied pharmaceutical training if he is to succeed, however such positions offer the greatest opportunities for general experience. In the large establishments where many scientific workers are employed, a high degree of specialization exists, some have no knowledge of pharmacy, others a knowledge of only one branch of the industry; nor is a pharmaceutical training necessary to all, for a botanist in the employ of such an establishment should be essentially a botanist with particular knowledge of the vegetable drugs and not a pharmacist with some additional training in botany. The chemist or pharmacist, however, should have general pharmaceutical training and it is to the education of this class that the present discussion refers.

The demand being established it may be asked if there is not a sufficient supply of such chemists. The existing condition is that practically no students have received or are receiving the kind of training desirable in such positions and graduate chemists with no pharmaceutical knowledge are usually employed, the alternative being to employ men who have obtained such knowledge at the expense of their general chemical training. A man with good chemical training can by years of experience obtain the necessary pharmaceutical knowledge, but it is much more difficult for the graduate pharmacist to acquire a sufficient knowledge of chemistry in this way. In a small establishment, however, where only one chemist is employed, he must have at the beginning, the pharmaceutical as well as chemical training. In the larger establishment the young chemist will probably be started on analytical work which does not require pharmaceutical training, although familiarity with the pharmacopœia and with medicinal products would be of great advantage.

Teachers of engineering and of industrial chemistry, wish to keep their students out of the drafting room or analytical laboratory, unless these may be expected to act as stepping-stones to executive positions or to actual engineering practice. In the factory where medicinal products are manufactured a certain amount of research work is necessary and many chemical engineering problems are solved; this work should be done by men promoted from the analytical laboratory, provided they have the essential pharmaceutical knowledge acquired either by training or experience, otherwise such positions must be filled by bringing in specially-qualified men if they can be found. Unless he has had a preliminary pharmaceutical training only the exceptionally energetic and studious chemist engaged upon some particular line of analytical work, can fit himself for such positions.

If it be granted that there is an active demand for drug chemists which is not supplied by the existing system of pharmaceutical education, the next step will be to determine the length and character of a course calculated to train men for such positions. This is a difficult subject and one which must receive the attention of many men engaged in educational and industrial work before satisfactory courses can be outlined. The writer will therefore only treat the matter in a general way and touch upon some details which are matters of personal observation.

All of the other branches of pharmaceutical work depend upon retail pharmacy for their existence, therefore it is highly desirable, if not absolutely necessary, for one who expects to advance very far in any line of pharmaceutical work, to have some information in regard to the retail drug business upon which to build his general knowledge of pharmaceutical matters. Actual experience in a drug store, is the best way to acquire such information, although if this is impossible, judicious reading and observation will go far toward supplying it.

There are many excellent chemistry courses in which the time given to the study of language, mathematics, physics, and general, theoretical and analytical chemistry, is properly proportioned, and the prospective drug chemist should receive just such training; in addition a thorough drill in assaying drugs should never be overlooked. The subjects provided for in the Pharmaceutical Syllabus should be included except where these are covered by the regular chemistry course. Some engineering knowledge is also essential to the manufacturing pharmacist, although it may not be necessary in drug inspection. It may be objected that the

proposed course of study would require six or seven years, but time could be saved in working out the details of such a course and it could undoubtedly be handled in a very satisfactory manner in five years. Would it pay students to take such a course? This can be answered in the affirmative, as most of the men now entering this field have had four years of college work and the additional year would enable them to command a higher salary from the beginning and would enhance their prospects of promotion to positions of greater responsibility.

At the present time graduate-chemists, available for positions in drug laboratories, are frequently deficient not only in pharmaceutical training, but also in their knowledge of physical and physiological chemistry, and it is exceptional to find men who have been trained to make proper use of the chemical literature. There is usually a lack of knowledge concerning the use and care of electrical and optical instruments, balances and weights, and other laboratory equipment, which results in inaccurate work and often in ruined instruments. There has been no engineering or mechanical training and, therefore, a simple mechanical drawing cannot be executed and neither special laboratory apparatus nor factory equipment can be designed. All of these things should be especially emphasized in a course in pharmaceutical chemistry and as the time devoted to such a course will be so fully occupied, extraneous subjects must be omitted. There will be no time for food analysis, mineralogy, metallurgy and other subjects not related to the chemistry of medicinal products, and their places should be taken by drug analysis and by the chemistry of industrial processes more closely related to pharmacy.

Mention must be made of the courses which have already been established for the purpose of training drug chemists. All of these courses must be classed as failures in some degree on account of a lack of coöperation between the industrial and official drug chemists and those engaged in educational work. Four-year pharmacy courses are, as a rule, only a little better than the shorter courses, in fitting men for practical drug work; instead of giving more thorough training in chemistry, the extra time is usually occupied with cultural and miscellaneous scientific subjects in a way which makes it appear that it is somewhat difficult to fill two additional years, when, as a matter of fact, a period of four years is too short a time even if every non-essential, though probably desirable, subject is omitted. A still more illogical course is the three-year course, where the regular two-year pharmacy course is supplemented by a third year of food and drug analysis. To attempt to combine food and drug work in a three-year course is absurd and can only lead to the encouragement and perpetuation of certain abuses which now exist. It would be much better if schools of pharmacy would use their influence to separate food and drug work, rather than to associate them more closely. Since it is unfortunately true that foods and drugs are linked together in the laws, it is particularly desirable that administrative officers should be able to secure the services of chemists who are thoroughly trained in pharmaceutical chemistry to carry on the work of the drug laboratory. The "cramming" of a lot of analytical methods, can result only in their empirical use, and this is one of the conditions which are now handicapping drug manufacturing and inspection. Let the chemical training be so broad and thorough that the principles upon which methods are based can be clearly understood; the limitations of the methods will then be recognized and

they will be used with judgment and modified when necessary to suit varying conditions.

It may be objected that very few men at present connected with drug work, have had the training which has been advocated, yet many succeeded, but it must be recognized that their success would have been earlier and ultimately greater if they had started with the thorough training which has been suggested. We have worked as well as we could with the material at hand, but if thoroughly trained pharmaceutical chemists had been available during the past eight or ten years, this branch of chemistry would be much further advanced and would be recognized by chemists in other lines of work; nor would it be possible for a well-informed chemical engineer to say to the writer, as was done a short time since, "Pharmaceutical work at present is entirely empirical, is it not?"

## PHARMACEUTICAL EDUCATION, OR THE EDUCATION OF THE PHARMACIST; WHICH SHALL IT BE?

---

JACOB DINER.

---

The question of education is justly occupying the minds of many men, educators and laity, and not the least interested in this question are those men who are chiefly concerned with professional education. The medical press for the last ten years has devoted a great deal of time and considerable space to the subject of medical education and the pioneer of American medical journals, the *Journal of the A. M. A.*, regularly brings a column or more on medical education and legislation.

In one of his usual masterly addresses, Henry P. Hynson some time ago sounded the key-note when he spoke of the pharmacist and his need of general education.

Therefore, in taking up the subject of Education as related to Pharmacy and the Pharmacist, we must closely differentiate between the education of the pharmacist and pharmaceutical education.

Modern pharmacy (or, should I say the modern pharmacist?) consists essentially of two integral parts. On one side we must have the professionally or rather specifically-trained man, on the other side we must prepare the same man to be commercially able to avail himself of every honest and legitimate means for the financial advancement of his business. How far shall we educate the embryo pharmacist for one and prepare him for the other,—does modern pharmacy really demand a professionally-trained pharmacist? Is the commercial training compatible with scientific education? To all of which I reply:—Most emphatically yes. The times have passed when the first essential to scientific attainments was utter lack of practical knowledge and disregard of the so-called worldly petty details such as dress, manners, sociability, etc.

The bespectacled professor who forgot his umbrella, his clothes, his meals, his wife, his family, his friends, etc., in short everything that was not ultra scientific still brings forth a sympathetic smile when we see him depicted in our so-called "funny" papers, but modern life and modern scientific progress has no place for him. Just so is the grouchy, misanthropic, sloppy, *yes, sloppy*, old, not to say antiquated, pharmacist in the dimly lit and indifferently-kept apothecary shop, out of place. Thus we must take our young men and teach them pharmacy consisting of the regular, more or less classic, curriculum and at the same time inculcate them with modern business methods so that they may advantageously market their professional attainments.

The New Syllabus of Pharmaceutical Education recently issued by the Committee and adopted by the New York State Board of Pharmacy assigns a number of hours for the subject of commercial pharmacy. No better step for the advancement of pharmacy and pharmacist could have been taken. The pity of it is that these hours are taken from the important subject of pharmacy (practical and manufacturing). Far better had they been taken from the relatively less important subject of Pharmacognosy. I do not want to be understood as holding the subject of Pharmacognosy as superfluous or non-essential. But we must admit that, outside of the specialist in this branch, it is of considerable less importance to the practical and practising pharmacist than are the subjects of Manufacturing, Prescription-Compounding and Merchandising, so long as the regulation Pharmacy course can only take up 1200 hours in two calendar years with a preliminary education of one year high-school or "its equivalent." Would I then want an increased curriculum with higher preliminary education? Yes, and no! For purely pharmaceutical training to meet the demands of the every-day variety of Pharmacy I would most emphatically oppose any attempt at increasing the requirements, either preliminary or professional. I would modify, I would alter, but I would not increase. I would change the foolish attempt to make an organic chemist, a trained pharmacognocist, a physiologist and a Latin scholar, out of a young man who has obtained 15 regents points by an examination in Russian, Italian, Spanish, or whatever his native tongue may be, and who does not know how to handle the simplest mathematical problem. For pharmaceutical education the New Syllabus is more than sufficient.

For the man who wants to specialize, who desires to go beyond the prescription and sales-counter increased training is demanded, and this is provided for in the Syllabus by higher preliminary requirements, more specific training and corresponding higher degrees.

When we come to the education of the pharmacist, that is a different matter altogether.

Let us for once refuse to imitate the ostrich. Let us look the situation in the face, calmly and honestly. Of what material is the great bulk of pharmacists composed? Are they really professional men, and if so, are they really educated men? For after all the collection of a certain amount of special knowledge does not constitute education. How many pharmacists are even approximately posted on the most important topics of the day, even including the European war and baseball? How many pharmacists get out of their four walls to see the world

and be seen by it? How many are interested in scientific and mechanical progress or even the progress made in our own branch? Out of 40,000 pharmacists or over, how many are members of the A. Ph. A., of the N. A. R. D., of their own State Pharmaceutical Association? At a paper read recently at the New York State Pharmaceutical Association the figures given for attendance at State Pharmaceutical Associations throughout the entire United States, showed, if my memory serves me right, an attendance of less than 10%. What Pharmacy needs for its rank and file is not increased Pharmaceutical Education, but increased Education of the Pharmacist!

---

#### THE COMPOSITION OF BLOOD.

When Mephistopheles insists that the bond he makes with Faust be signed with blood, and remarks, "Blut ist ein ganz besondrer Saft" (Blood is an extremely peculiar juice), even Goethe, great scientist as he was, had no conception of how wonderful a fluid it is. Human blood consists of a transparent yellowish liquid called the plasma, in which float red corpuscles and at least five kinds of white corpuscles, usually called leucocytes. When the health is normal, each cubic millimeter of the blood contains about 5 million red corpuscles and 7500 leucocytes. The enormous numbers of these corpuscles, red and white, may be faintly realized when it is stated that a cubic inch is equal to nearly 16 thousand cubic millimeters. These cells are greatly changed both in number and condition by ill health. Some of the white corpuscles are called phagocytes (cells that eat) because when the blood is invaded by disease-causing (pathogenic) parasites, it is the business of the phagocytes to run them down and make a meal of them. So wonderful is the behavior of the phagocytes that one eminent scientist recently said of them, "The mononuclear and polynuclear leucocytes have qualities which it is very difficult to call anything else but consciousness." That is to say, each cell is endowed with a mind that directs its marvelous activities. But more wonderful than the corpuscles that it contains is the plasma itself. It can be so changed or modified by zymotic diseases or by certain serums or vaccines that the patient will be immune for years or even for life against a second attack from the same disease, but he will be safe from no other disease of the infectious kind unless he has been vaccinated for it with the proper serum. Blood is indeed an "extremely peculiar juice." How peculiar, who shall say?—*Ambition.*

## Section on Historical Pharmacy

Papers Presented at the Sixty-Second Annual Convention

### FORTY-FIVE YEARS OF MANUFACTURING PHARMACY.

FRANK O. TAYLOR, PH. C.

In view of the fact that the American Pharmaceutical Association is meeting this year (1914) in the recognized center of the pharmaceutical industry in America, the Secretary of the Historical Section suggested that a brief history of Parke, Davis & Company, and some account of their connection with advances in pharmacy and medicine would be appropriate to the occasion, and of special interest to all those present who have made a tour of inspection through these laboratories.

To you gentlemen, who, in your daily work, have reason to be familiar with the preparations of Parke, Davis & Company, it is almost unnecessary to speak with regard to present conditions and you are, in a measure, familiar with the extent of these laboratories and the purposes that animate them. It is, however, probable that many of the present members of the American Pharmaceutical Association are not familiar with the early history and growth of this firm and particularly the connection it has had with the development of pharmaceutical preparations; so it will not be amiss to give a brief account of the firm itself before speaking of its connection with medicinal progress.

#### DEVELOPMENT OF PARKE, DAVIS & CO.

Up to the time of the early sixties it had been the almost universal custom for each pharmacist to prepare for himself such galenical preparations as he needed, but about this time several firms began manufacturing work on a small scale, developing this in most cases in retail drug stores that had been established for some years. The idea of centralized manufacture of medicinal preparations was just in its infancy and was probably not recognized as such at that time, but there seemed to be a field for such a firm, and Dr. S. P. Duffield, after having previously entered into two brief partnership arrangements with other men, formed a co-partnership with H. C. Parke on May 7, 1867. This firm continued to do business until 1869, when Dr. A. F. Jennings bought out the interest of Dr. Duffield and the firm became Parke, Jennings & Company, George S. Davis being one of the company. On November 16, 1871, Dr. Jennings retired from the firm and it became, for the first time, Parke, Davis & Company, existing as a co-partnership, and continued as this until January 14, 1875, at which time, as it was developing rapidly and it seemed desirable to perpetuate the firm in some form better than a

\* Read before Historical Section, Detroit, 1914.

co-partnership, it was incorporated with a capital stock of \$125,000, of which \$81,950 was paid in.

All this time the laboratory had been located at the corner of Cass and Henry Streets, Detroit, with an office at the same place, and not until 1875, about the time of incorporation, was it moved to its present location. At this time the office was moved to 52 Larned Street, West, where it remained until 1877, when it was transferred to the site of the present laboratories. From this time on the laboratories gradually increased in size until at present they cover several blocks and have, besides their Detroit laboratory, branches in Canada and England, where manufacturing is carried on, and branch offices in almost all parts of the world.

*Guiding Principles:*—The tendency of modern business has, for many years, been to emphasize the necessity of absolute integrity, both in fact and in spirit, in all dealings, and this idea that has begun to very thoroughly permeate all our business institutions was, it seems to me, one of the chief reasons for the rapid and permanent growth of a business that begun so short a time ago and has increased so tremendously. I can not better illustrate what I mean than to quote from a little leaflet printed many years ago when the firm was young, setting forth their beliefs, and which they entitled "Our Creed and Code":—

"We believe, that, in combating disease, only the best quality of drugs is permissible, and that to their manipulation should be applied the highest scientific skill.

"We believe that the issuing of inferior medicines of any kind is unjustifiable from any point of view.

"We believe in standing solely upon the intrinsic merits of our preparations, and in making no false pretenses; in doing the best that scientific knowledge and skill will accomplish and in doing it honestly and faithfully.

"We believe in working fully in harmony with our pharmacal and medical friends, and in gratefully accepting any suggestions that may tend to our mutual profit. Our watchwords are *Purity, Accuracy, Reliability.*"

*Historical Periods:*—The history of Manufacturing Pharmacy as a whole and of Parke, Davis & Co., may be divided into four periods characterized by the most important activity of the time, which periods are practically identical in date especially the last three, as this firm in each of these was the leader in the special work involved. These periods are as follows:—

1. Formative Period—1867 to 1874.
2. Botanical Research Period—1875 to 1882.
3. Standardization Period—1882 to 1894.
4. Biological Period—1895 to present time.

These are of course not sharply defined, the work characteristic of each of the last three was in the course of development for some time before the dates assigned and the appearance of a new line of work by no means indicated a termination of previous endeavors, in fact, it frequently widened the scope of all investigations. For these reasons we cannot deal with each period by itself except in a general way, but in most cases trace each line of products or development of process through its entire history. For want of time these accounts must perforce be brief as possible.

*Fluid Extracts:*—The first products manufactured in the early laboratory were a few chemicals and a line of fluid extracts, and it is interesting to note that the

firm considered the process of maceration of the drug with the menstruum and extraction by hydraulic pressure as the most satisfactory one, as it avoided the use of heat in concentrating weak percolates. It is true that quite a while before this, the process of percolation had been introduced, but the firm, feeling that the experience with this method which they and others had so far acquired, was not sufficient to insure it giving the best possible fluid extracts on a small manufacturing scale, and also being fearful of the vacuum apparatus of that time, decided to adhere to the older method for some time longer and in one of their early price lists state, "We neither percolate nor use heat in any form whatever."

In 1882 a combination process involving percolation as well as maceration was evolved, and this in a few years gave way to percolation exclusively. At the present time, as everyone knows, the process of cold repercolation has been so carefully worked out that it is the best means of extracting drugs and the most economical of solvents used. To the simple percolation by gravity there is now, in many cases, added the use of compressed air, which, besides hastening the percolation, renders it more thorough by forcing the menstruum into the structure of the drug.

After the business had been organized and acquired a little momentum through a few years of experience, the members of the firm began to look around for new things that would be both useful to pharmacists in general and profitable to themselves. As fluid extracts of various drugs were so widely used, it was but natural to look for unknown or little used plants that might be of medicinal value, and to this end, a systematic search was begun about 1874, which continued for many years, and gradually developed along other lines. If a new plant was heard of from the far west of the United States or some foreign country, if the suggestion was made by any physician through correspondence or by a published paper as to the efficacy of a heretofore unused plant, it was immediately investigated and if it gave promise of being really useful, supplies were obtained and the fluid extract distributed to physicians.

*Botanical Research:*—At this same time, through these same years, an immense volume of literature was prepared by the firm from the reports of physicians and other scientific men all over the country giving detailed accounts of the botanical character of the new drugs and their medicinal properties. Some few well-known preparations are generally recognized as having been introduced by Parke, Davis & Company, but it may surprise you even as much as it has the writer, to find how many drugs now prominently known, were originally brought to the attention of the medical profession by this young firm, especially when it is considered that at the time they were doing this work, the financial outlook was anything but pleasing, as the influence of the panic of 1873 was still strongly felt.

In the course of these investigations Parke, Davis & Co., through representatives, explored the northern parts of California, Washington, Oregon, British Columbia and Mexico. One representative was sent to the Fiji Islands to obtain a supply of the drug Tonga; another going to the West Indies brought back Jamaica Dogwood and a few other less important drugs. A special representative, dispatched in 1881, made a trip from the mouth of the Amazon River about 2500 miles into the interior, and as a result of this expedition the drug Manaca

was added to the growing list of new remedial agents. About the same time another representative proceeded inland from Buenos Aires on horse-back clear across the mountain range to the Pacific coast. This work resulted in the discovery of the herb Chekan, and the obtaining of supplies of Boldo, Quebracho and some other Chilean drugs. In 1885, Dr. H. H. Rusby made an extensive trip in South America, in the interests of Parke, Davis & Co., as a result of which he brought back much scientific information and among many other plants the drugs Pichi and Cocillana, together with obtaining extensive supplies of Coca from Peru.

As you are aware it is almost impossible to locate absolutely the first medicinal use of a drug that has been known for years and a distinction must be made between the one who may first find a medicinal use for a plant and him who makes this common knowledge or brings a drug from obscurity to a place of more or less prominence in *Materia Medica*.

The somewhat extensive list following includes all but a few drugs of evanescent usefulness that have been introduced to medical use by Parke, Davis & Co. In all cases preparations of these drugs were practically unknown in the United States except as they may have had a very restricted local use and some of the most important ones were absolutely new to the medical profession, as for example, Cascara, Yerba Santa, Berberis, Grindelia, etc. The writer has spent considerable time going over old literature of the firm and other journals to verify as far as possible, the priority of introduction of these drugs and has found a number for which the firm does not ordinarily claim credit that they seem to have been chiefly instrumental in introducing, at least in the United States. It has not been possible to make a complete search of journal literature and find the earliest mention of all these drugs but the dates given being those at which the Fluid Extracts were first put on the market by Parke, Davis & Co., undoubtedly are the first appearance of such preparations of all these drugs. The names in italics, are drugs recognized in the U. S. P. eighth revision.

1869—*Black Haw*.  
 1874—*Guarana*.  
 1874—*Eucalyptus Globulus*.  
 1874—Bearsfoot.  
 1875—*Coca*.  
 1876—*Cereus Grandiflorus*.  
 1876—*Muskroot (Sumbul.)*  
 1876—*Jaborandi (Pilocarpus.)*  
 1876—Sundew  
 1876—Evening Primrose.  
 1876—Bladderwrack.  
 1876—*Damiana*.  
 1876—*Yerba Santa*.  
 1876—*Grindelia robusta*.  
 1876—Sandalwood.  
 1877—*Grindelia Squarrosa*.  
 1877—*Ustilago Maydis*.  
 1877—Kava-Kava.  
 1877—*Ailanthus Glandulosa*.  
 1877—*Urtica Dioica*.  
 1877—*Berberis Aquifolium*.  
 1877—Boldo Leaves.  
 1877—*Cascara Sagrada*.  
 1877—Five-flowered Gentian.  
 1877—Kamala.

1877—Guaco.  
 1877—Paraguay Tea.  
 1878—Cedron Seed.  
 1878—Coto Bark.  
 1878—*Cereus Bonplandii*.  
 1878—Quinine Flower.  
 1878—Areca Nuts.  
 1878—Shepherd's Purse.  
 1878—Yerba Reuma.  
 1878—Great Laurel.  
 1878—Indian Blackroot.  
 1879—Jamaica Dogwood.  
 1879—Rhus Aromatica.  
 1879—Manaca.  
 1879—Quebracho Bark Powd. F. E., 1881.  
 1879—*Saw Palmetto*.  
 1881—Tonga.  
 1881—*Corn Silk*.  
 1882—Sierra Salvia.  
 1882—*Convallaria*.  
 1882—Cheken.  
 1886—Pichi.  
 1888—Cocillana.  
 1908—*Cannabis Americana*.

As I have said, some of these drugs had been used in their local habitat for a long time, as for example, Coca, which had been known for centuries in Peru and used widely in the mountains of South America, and its chemical constituent had been investigated in Europe, but it had not been introduced into this country to any appreciable extent. Again, Manaca had, prior to 1879, been recognized in the Brazilian Pharmacopœia, but was practically unknown outside this country and had not been used in the United States. Sandalwood has, of course, been known in India for centuries, but its medicinal use, especially in the form of a fluid extract of the wood, had received practically no attention in the United States.

It is interesting to note at this time that of the total number of drugs mentioned, twenty of them are at the present time recognized in the United States Pharmacopœia or National Formulary, and thirty-two of their fluid extracts are still in sufficient demand to warrant manufacture by Parke, Davis & Company. Another interesting feature is that the majority of these drugs appeared within three years, viz., 1876-77-78. Altogether approximately fifty different drugs have either been introduced as entirely new by this firm, or have been taken from great obscurity and brought to some degree of prominence.

*Publications:*—Closely associated with the introduction of new remedies was the dissemination of knowledge concerning them, and so from occasional bulletins giving information on this subject, there gradually developed a systematic series of publications. A Publication Department was organized entirely independent of the manufacturing and sales work, and journals dealing with pharmacy, therapeutics and surgery in their purely scientific aspects began to be published, not all of them at once, but in the course of time.

From the early bulletins there first developed a journal entitled "New Preparations," beginning in January, 1877, and published quarterly for this and the next year, and then monthly during 1879. The legend on the title page indicates its purpose, viz., "A quarterly journal of medicine devoted to the new therapeutical agents." In 1880 the scope of this publication was modified somewhat, and its size increased, and it began to be published as "The Therapeutic Gazette" devoted exclusively to therapeutics. From that time since, it has continued to the present day as one of the well known medical publications of the country.

As a publication of a different and more local character, there began in 1877 "The Detroit Lancet" which, in 1886, was changed to "The American Lancet," and so continued until 1893.

In January, 1883, another journal entitled "The Medical Age" was begun which, as referred to on the title page, was "A semi-monthly journal of medicine and surgery." The publication of this continued until the close of 1906, at which time it was incorporated with The Therapeutic Gazette.

In April, 1895, a somewhat similar journal was introduced under the title "Medicine" which was a monthly journal of medicine and surgery. In January, 1907, it was also combined with the Therapeutic Gazette.

These facts are probably generally known, but it may not be so well understood that for many years this firm were the publishers of the Index Medicus of world-wide reputation. A brief statement of the vicissitudes of this publication may not

be amiss. It was started in 1879 under the editorship of Dr. J. S. Billings of the U. S. Army, and Dr. Robert Fletcher as his assistant, and published by F. Leypoldt in 1884 of New York. It continued thus until the death of Mr. Leypoldt in 1884, when an announcement was made that it would be discontinued, as it had been published at a considerable loss, and they did not know of anyone who would finance it. After three months intermission, it was taken over by Mr. George S. Davis, representing the Publication Department of Parke, Davis & Company, brought up to date in the first issue of 1885 and continued to be published under these auspices until April, 1895. The publication was then taken over by the editors and after some other changes during the next few years, it was finally placed in the hands of the Carnegie Institute in 1903, where it now remains.

As exclusively related to pharmacy and of interest to pharmacists, there was begun in January, 1887, "The Druggists' Bulletin" which was stated to be "A monthly Epitome of Pharmaceutical progress and news." Starting with a very small beginning, it continued under this title until the close of 1890, when it was changed to "The Bulletin of Pharmacy," as which it is now well known to you all.

Of these various publications, the two which now remain as a sifting out of that which has gone before are "The Therapeutic Gazette" and "The Bulletin of Pharmacy."

*Standardization:*—As the activity in the search for new drugs began to wane, there appeared the forerunner of what, it seems to me, is the most important advance in pharmacy that has occurred in modern times, viz., the application of the principle of standardization, or uniformity in production of preparations of drugs. With no flourish of trumpets and little realization of what is heralded, in September, 1879, there appeared a preparation known as *Liquor Ergotæ Purificatus*, which was a fluid preparation of ergot, standardized by a simple form of assay so that each different lot was of uniform character. The assay appears to us, at this day, as very crude and inefficient, but we must remember that this was simply the beginning, and any kind of an attempt to give uniformity of strength was an advance upon untraveled ground.

According to the best researches of the time, the activity of the ergot was supposed to be chiefly in the sclerotic acid, and a crude estimation of this was made by the precipitation of the organic acid with lead acetate. The standard was this: "Ten cc. of the normal liquid require for complete precipitation, 100 cc. of a solution containing 1% of crystalized lead acetate."

This truly appears to us with the retrospect of forty-five years of experience, as almost laughable, but it was the best that the knowledge of the times afforded and was a step toward the dreams of the future which were beginning to take form in actuality. With this there began a systematic investigation of the possibility of rendering uniform, fluid preparations of many drugs with the result that in February, 1883, there was publicly announced a list of twenty normal liquids which were actually fluid extracts standardized by some form of assay, in most cases an estimation of the alkaloids which they contained. The man responsible for the beginning of these assayed fluid extracts and who established

the analytical methods for their control is Dr. A. B. Lyons, to whom in this, as in many other things, pharmacy owes much.

The process for the determination of the alkaloids chiefly employed was the now obsolete method of titration with Mayer's reagent, but it is evident that the years from '79 to '83 had been well spent, when we note that the alkaloidal standards of strength adopted for preparations of "normal liquid belladonna" leaves and root were, in each case 0.44% of alkaloid and the present U. S. P. standard for fluid extract belladonna root is 0.4 and for the leaves 0.3%, the "normal liquid ipecac" was 1.5% alkaloid, the same as now official for the fluid extract. The standard for "normal liquid nux vomica" was a little lower than the present U. S. P. standard for fluid extract, it being then 1.5% of total alkaloids as against 1% of strychnine at the present time. This last mentioned fluid is chiefly interesting for the fact that the assay process more nearly approximated that used at present than any other, it being carried out by adding a few drops of dilute sulphuric acid to the liquid, evaporating off the alcohol, washing the residue with ether, taking it up at the same time with water, finally rendering alkaline with caustic soda, shaking out the alkaloid with a mixture of chloroform and ether, and weighing the product so obtained.

Of the further development of the chemical standardization of drugs and their preparations it is almost unnecessary to speak, but it is worthy of notice that the work instituted by this firm and followed in later years by a host of helpers has always kept far in advance of the official requirements of the various Pharmacopœias as they have been established.

As an extension of the work of standardization of drugs and their preparations, there appeared, with the beginning of the biological period in 1894, the first fluids that were standardized by physiological assay as distinct from any chemical assay. It is an interesting coincidence that the first fluid so standardized was also the first one whose uniform production had been attempted by a chemical assay, viz., fluid extract Ergot. Following this there came, at intervals, standardized products of a number of other drugs, such as the various heart tonics with which you are entirely familiar. The development of different methods of physiological test is outside the scope of this paper, and has been described extensively in other publications. Suffice it to say that this general principle, whether applied along chemical or physiological lines, has undergone many changes with the establishment of improved methods of work, and still gives promise of much further development that will widen its present extensive scope.

Going back now to an earlier time, let us consider very briefly some of the different lines of pharmaceutical manufacture that have been developed. It would require too much time and space to treat separately and in detail different lines of products like pills or tablets or ampoules, etc., and so perforce they must be considered very briefly, emphasizing only the most salient features of improvements that from time to time have been made in their preparation.

*Tablets.*—There have been many interesting features in connection with the development of tablet manufacture, but none of them are such that they can be called important advances in pharmaceutical manufacturing, and it is only necessary to say that the gradual development of this line of products during the years

that they have been in vogue has had to do chiefly with the mechanical perfection of the tablets, their speed of solubility or disintegration, and detailed knowledge about how best to handle an almost infinite variety of substances used in them.

The most important manufacturing advance has been the development of new machinery, so that where originally a few tablets might be made by the retail druggist by hand and later by a machine giving a single tablet at each impression, we have now especially designed machinery such as has been built in the machine shops of Parke, Davis & Co., which have a capacity of a million and a half tablets per ten-hour day. This development has recently been described at length by Dr. L. E. Kebler in his paper presented to this association last year.

*Pills:*—The origin of pill manufacture in a small way is lost in obscurity. By this I mean the preparation of pills by the retail druggist. It is very natural, therefore, that on the manufacturing scale, it should be one of the first products made, together with the fluid extracts of drugs. Here again the development of the product coincides with the development of automatic machinery, and you are all of you well informed regarding recent improvements in such machines. The strides that have been taken measure up well with those in tablet manufacture. Where their production was formerly, by hand, limited to a few thousand per day, a single machine will now turn out anywhere from five hundred thousand to two million pills in a day, depending upon the size of the pill. The old method of gelatin-coating pills by impaling them on pins and dipping in gelatin solution was done away with by Parke, Davis & Co. when they originated the machinery for holding the pills by vacuum while being dipped.

The most important modification of pills in the last few years is the introduction of the so-called "Soft Mass Pill," so made that the interior is quite soft and protected by the hard shell of the coating, just thick enough so that the entire pill may be easily crushed between the fingers. This pill is made by the mass process and retains its softness for many years.

In this connection it is interesting to note that Parke, Davis & Co. who introduced this pill in 1909, evidently felt that this was a desirable attainment a great many years ago, as back in 1875, they are careful to state that their pills are especially desirable because they are "coated while the mass is yet soft." At that time, however, the idea of the soft mass was not at all what it is to-day.

*Pepsin:*—The extensive use of digestive ferments is of comparatively modern origin, and this firm has had very much to do with the development of pepsin manufacture and rendering the use of this digestant popular and convenient. The introduction of different strengths of pepsin as made by Parke, Davis & Co. may be considered as identical with the development of pepsin manufacture thus indicated.

In 1874 they introduced a Saccharated Pepsin of such a strength that "five grains would digest sixty grains of coagulated albumin," being thus of a 1:12 strength. This was considered a very excellent product, although so weak that it would be counted as worthless to-day, and thrown away as waste. The mixture of the Pepsin with milk sugar was necessary because of the exceedingly hygroscopic nature of Pepsin thus made, owing to the presence of a considerable amount of peptone, which they had not yet learned how to separate from the Pepsin. In February, 1881, there appeared a pepsin of which they were rather

proud, which was dignified with the name "Concentrated," it being so strong that one grain would digest 100 grains of coagulated albumin, but this achievement was very quickly improved upon so that in February, 1883, there was presented a so-called "pure" pepsin, which was stated to have an activity of 1:450 to 1:500. In the meantime, the U. S. P. of 1880 had appeared and had made official a Saccharated pepsin with a strength of 1:50. About the same time some one got the idea that pepsin prepared from sheep stomachs, was in some way better than that prepared from hogs stomachs, so with the idea of being fully abreast of the latest developments the firm put out at this time a so-called pure Sheep Pepsin having a strength of 1:350 to 1:450. This sheep pepsin was short-lived, however, and in a few years was again taken from the market as there was no reason why it was any better medicinally than the established variety. In January, 1885, the development of pepsin had proceeded to such an extent that the peptones could be largely removed and the pepsin produced in a scale form which is now so universally known. Between this and the year 1888 continued researches brought about a tremendous advance and in that year a pure pepsin in scale form free from peptones and marked "Non-hygroscopic," (which it certainly was as compared to previous productions) and having a strength of 1:2000, was placed on the market; also a powdered pepsin of the same strength was supplied, and for the first time there appeared a solution of pepsin in glycerin called Glycerole Pepsin, of such a strength that one minim would digest 100 grains of coagulated albumin.

There was now no further change in commercial supplies of pepsin until 1893, at which time as the result of continued and rather epoch-making experiments, there were placed on the market a line of pepsins of different strengths in scale form, including 1:2000, 1:3000 and 1:4000 strength, a glycerole pepsin having a strength of 1:300 and while not regularly listed, it was arranged that supplies of pepsin having any strength up to about 1:15000 would be furnished on demand. The next year, 1894, appeared the 1890 Revision of the U. S. P. which made official a pepsin of a strength of 1:3000 and a saccharated pepsin of 1:300, which have remained to the present time as the official standards.

At the same time, with the development of the pepsin manufacture, there has gone with it hand in hand the development of methods of testing pepsin, and while the strengths of pepsin as claimed many years ago were approximately correct, they are certainly not the same as would be shown by our present day methods of assay. The pepsin supplied even up to as late as 1890 or 1893 was probably much weaker than would be indicated by our present methods of assay. The general idea of the test has not varied greatly, but our experience has increased and our interpretation of results has been modified. This is very forcibly shown by the fact that quite recently a test was made of a sample of pepsin prepared about twenty years ago and which, at that time, was considered to be 1:20000 strength. This has been kept under the best possible circumstances, so that deterioration that had occurred was certainly very little, but the test showed that it would now be considered only about 1:10000. The fact that the U. S. P. standard has not varied for almost twenty years past does not indicate that there have not been advances in this length of time for I am able to show you to-day a

sample of pepsin testing 1:25000 by present tests, which is therefore, approximately five times as strong as the pepsin prepared twenty years ago. This high powered old sample was more the result of good luck than accurate knowledge and it was practically impossible to duplicate it, but this new sample can be duplicated at any time, although, of course, the expense of making so powerful a product would be considerable, but strengths of 6000, 8000 and 10,000 are easily made.

As in the manufacture of extracts of drugs, so in pepsin manufacture the development of highly efficient vacuum apparatus has had much to do with the improved processes.

*Pancreatin*.—As closely associated with pepsin, we naturally think of the ferment Pancreatin. Here the development has not been so spectacular as in the case of pepsin, but it is nevertheless considerable. In 1877 a saccharated pancreatin was placed on the market, for which no standard of strength was given, there being no recognized way of determining the strength at that time.

In February, 1881, there appeared the following test which, crude as it was, attempted to give some definite information about the product: "Ten grains will emulsify  $\frac{1}{2}$  to 1 oz. cod liver oil with water in sufficient quantity." This test was continued as a standard until 1884, at which time a so-called "pure" pancreatin and also a liquid concentrated pancreatin were put on the market, the first of which being of such a strength that five grains would peptonize one pint of milk in half an hour, and the latter required two fluidrachms to accomplish the same results. The same standard of strength, as far as the peptonizing of milk is concerned, remains to the present day. The Eighth Revision of the U. S. P. established a starch conversion test requiring that one part of the pancreatin should be able to digest 25 parts of cooked starch.

The development of a commercial pancreatin supplied by Parke, Davis & Co. since the introduction of this Pharmacopœia has gone to such an extent that its regular product now has the ability to digest 150 parts of starch for each part of pancreatin.

*Taka-Diastase*.—For many years it was known that a ferment, having some digestive action on starch, was produced during the growth of various fungi. Researches, both in Germany and Japan, began to develop considerable information on this subject, and in 1895 the first medicinal application of a ferment of this kind was made, when Parke, Davis & Co. introduced Taka-Diastase as a result of the researches of Dr. Takamine. As first supplied it had the power of digesting or converting into assimilable substances one hundred times its weight of starch, but, through continued research, it has been possible to greatly increase its digestive activity, so that, at the present time, it has three times its original strength.

*Capsules*.—Turning now from medicinal products to what may be considered accessories in pharmaceutical practice, we would note especially the development of empty capsules. These were not original with this firm, having been first prepared in a very crude form by A. Mothes, a French pharmacist, in 1833, and first made in the U. S. by H. Planten in 1834 or 1835, but they were not recognized as being particularly valuable, and no perceptible advance was made in their

manufacture for many years, and the history of the greatest development of capsule manufacture is coincident with the connection of Parke, Davis & Co. with their production. In early years the firm did not actually own the plant, but they controlled the entire output of an associated factory, which was to all intents and purposes their own.

The first capsules which they listed were in 1875, and consisted of three sizes, what are now known as Nos. 1, 2 and 3. They were still rather crude, but an attempt was made to give them a smooth and transparent appearance, and to produce a body with cap slightly larger so that they would fit properly together, and the gelatin used was the best obtainable at that time, as at present. The novelty of the empty gelatine capsules is very well shown by the description of them in advertisements in the late '70s, such as the following: "Our capsules are composed of two small tubes of prepared gelatin, one sliding into the other, and each closed at one end. The remedy employed is then separated into the proper dosage, one of which is placed in the smaller tube, which is then telescoped into the larger. It is now in the shape of a small cylinder,  $\frac{1}{2}$  inch in length,  $\frac{1}{4}$  inch in width, closed at both ends," or the following: "The gelatin on being moistened becomes slippery and is readily swallowed with the aid of a little water."

Though they were so little known to the pharmacist the public knowledge of them was even less, as was evidenced by an item in the Louisville Medical News in 1877, where a physician states that an intelligent gentleman had been given capsules to take without specific directions, and later informed the physician that he "did not like them at all," his idea of taking them being "to peel off the hulls and put the stuff in water."

From a very slow and laborious process, the manufacture of empty capsules has come to be one of speed and remarkable perfection, and nowhere can be found a more wonderful development of special machinery than is connected with the capsule industry. More space could be given to this alone, but for further information, which it is impossible to include here, reference may be made to the article by Warren Wilkie in the Bulletin of Pharmacy, 1913, page 382.

*Biological Manufacture:*—We come now to what we have called the fourth period in the development of manufacturing pharmacy, viz., the biological period, and use the term in a broader sense than it is popularly employed. In this connection one naturally thinks of vaccine for producing immunity against small-pox, but this was developed nearly one hundred years before the appearance of antitoxins or bacterial vaccines.

On the border line between medication by drugs of mineral or vegetable origin on one side, and products derived from bacteria on the other, lie a number of animal substances which modern materia medica includes, as some of its most potent agents. Substances that, to one unfamiliar with the trend of medical research through the last twenty years, would seem to savor of the necromancy of the middle ages. The results obtained from the various products of the so-called "ductless glands," have been so remarkable that they have attracted considerable popular attention, and have, in some cases, almost revolutionized the medical treatment of obscure and hitherto baffling diseases. This work, very naturally,

began first, with the use of the desiccated glands themselves, followed, almost immediately, by attempts to isolate some definite active principle. As a result of this, first, and so far, most important, there was isolated by Dr. Takamine, the active principle of the suprarenal gland, Adrenalin, which became commercially available in January, 1901. Since that time it has risen rapidly into the very front rank of important remedial agents and it needs no further statement concerning it in this connection.

As a more recent and almost equally important work, though in somewhat different line, there has come the commercial development of an extract of the pituitary gland, known by this firm as Pituitrin, and supplied first in 1909, embodying the active constituent of the posterior lobe of the gland. The exact nature of this active principle has not yet been definitely determined, but at the present time much attention is being paid to it and also to the value of the anterior lobe of this gland, for a long time discarded and considered of no value.

Along with the use of these two glands medicinally, there has come about also the use of the thyroid gland, either in desiccated form or as some especially prepared substance derived from it. The thyroid gland has been under investigation for many years and the exact nature of its active constituents is not yet understood, but there probably remains, in the future, much knowledge of this gland that will be of even greater value than that possessed to-day.

The gradual development of definite therapeutic uses for a number of other glandular products is now in progress, most prominent among which may be mentioned the Pineal and Para-thyroid glands, but what shall be the results of this, as regards the isolation of any definite active body or a thorough understanding of their uses, and the employment of them in therapeutics, is yet chiefly a thing of the future, although apparently not far distant.

What shall be the ultimate result of the study of these glandular products will remain for some historian of many years to come to set forth.

The commercial beginning of what is generally spoken of as biological work was in 1894, and the events that preceded it are worthy of a moment's notice. In 1887 Professor Sewall of the University of Michigan directed attention to the immunization of pigeons against rattlesnake venom. This is probably the first published reference to the establishment of immunity. Following this, during the next six or seven years, there appeared a number of papers dealing with the establishment of immunity against various poisons, such as ricin, abrin, etc. of vegetable origin, and toward the close of this time there came the epoch-making work of Roux, Behring, his assistant, Kitisato and Aronson. The publications of Behring and Roux really mark the beginning of the idea of producing, on a manufacturing scale, a substance that would produce immunity to diphtheria and other diseases which were of bacterial origin.

The firm of Parke, Davis & Co. early saw the possibilities in the field so opened up and in 1894 established, in a small way a department for pharmacological work and for the production of diphtheria antitoxin. The first equipment was small, and the total number of animals included a few guinea pigs for necessary tests and three horses for the production of the antitoxic serum.

Early in 1895, public mention was made of the fact that they would, in a very

short time, be able to supply diphtheria antitoxin, and by 1896 three different packages were on the market, viz., one containing 600 units, one of 1000 and one of 1500. The next year a bulb containing a prophylactic treatment of 250 units was placed on the market, and one of 2000 units.

In 1898 appeared, for the first time, a package containing 3000 units and from this time on, for some time, the strength of dosage was not greatly increased, but the effort was made to cut down the amount necessary to obtain the same potency. Very considerable advances along this line had already been made. The first serum made contained about fifty to sixty antitoxic units per cc., but very quickly the strength of the serum was increased, and it is a notable fact that one of the most potent serums was taken from a horse used in 1898, this serum being so powerful that one cc. contained 2000 antitoxic units. At that time, the reasons for this remarkable potency were not well understood, but it seems now that it was due to some unknown difference in the animal, as great variation is found in the serum that is obtained from different animals. Since that time the continued effort has been to increase the potency of the serum by concentrating it in some way after it is first obtained, as the result of which the so-called serum globulins or concentrated serum have been supplied, which now contain a very much larger number of antitoxic units.

In 1897 antistreptococcic serum, and in the same year anti-tetanic serum both in liquid and dry form, were placed upon the market. An anti-tubercle serum appeared in 1898, and in 1899 and 1900 respectively there appeared, for veterinary use, two new products, blackleg vaccine, and anthrax vaccine, which were of a different type and are more closely related to the bacterial vaccines of later development than they are to serums.

The brilliant and rapid development of bacterial vaccines is of such recent date that all of you are well acquainted with it, and there is no need to do more than to record the fact that it has its origin in the work of Sir A. E. Wright and that the first commercial preparation of bacterial vaccine was made by Parke, Davis & Co. in 1907. Since that time the number of them has greatly increased, and the development has been so rapid and is still going on to such an extent that these productions can not properly be treated in a historical paper as they have not yet the antiquity that renders them of historical nature, but are a very present and active force in pharmaceutical work.

As the latest addition to biological products for medicinal use, we come to the phylacogens which give promise of having an even more brilliant future than their precursors, the bacterial vaccines, but again these are of so recent origin that they are not appropriately treated in a paper of this type, and can only be mentioned.

In taking a general survey of the pharmaceutical industry from a manufacturing standpoint, one of the most striking developments is that of the apparatus and machinery employed and the use that has been made of machines originally designed for other industries. It is characteristic of the development of medicine and pharmacy in general that they have been quick to take advantage of knowledge gained from every available source and this has been especially true of apparatus employed.

We have already noted something of the remarkable development in special machinery in the manufacture of capsules, pills and tablets, all of which are peculiar to the manufacture of medicines, and one could very easily deal with the development of this machinery entirely apart from any of the products and processes themselves. Aside from the special machines just mentioned, probably no one thing has had so much effect on medicinal products as the great improvement in different types of vacuum apparatus in the last fifteen or twenty years. Vacuum stills for the recovery of liquids or the concentration of fluids where the solid residue is desired, vacuum dryers for the handling of products such as dry extracts of drugs or granular effervescent salts, and even the use of vacuum pumps for filtration, for the handling of liquids in quantity and numerous other minor purposes make it unusually important in a wide scope of work.

From the baking industry we have taken over the type of mixers there used as being the best for pharmaceutical processes; from the flour mill we have adapted the roller mills to be used in handling tablet granulation; from the liquor industry we have adapted stills and vacuum pans of various forms; from the laundries we have taken special types of centrifugal machines; from the sugar industry, centrifugal machines of different design for other purposes, from the manufacture of confectionery we have derived lozenge machinery and notably the type of pans for sugar-coating pills and tablets which are the same as have been used for sugar-coating nuts; from the paint manufacturers we have taken over the mills for grinding paints and put them to use for grinding ointments and have taken their automatic filling machinery for use in filling tubes of tooth-paste ointments, etc. In fact, wherever a machine has been found that could, in any way, be adapted to pharmaceutical practice, it has been done, and used as it was, or, as frequently the case, after some modifications.

It is sometimes hard for the historian to refrain from assuming the role of prophet, but it is plainly evident to all that a great change in medicinal preparations is occurring, the old galenicals in many cases giving way to products from the biological field, and it requires no seer with supernatural vision to see still greater changes in the future, both in materials and methods, and the establishment of a more potent and definite materia medica.

*Laboratories of Parke, Davis & Co.*

#### STATES HAVING RECIPROCAL REGISTRATION.

The following states now have reciprocal license privileges for pharmacists through the work of the National Association of Boards of Pharmacy:

Active—Alabama, Arkansas, Arizona, Connecticut, Delaware, Florida, Georgia, Idaho, Illinois, Indiana, Iowa, Kansas, Kentucky, Louisiana, Maine, Maryland, Massachusetts, Michigan, Minnesota, Missouri, Montana, Nebraska, New Hampshire, New Mexico, North Dakota, Oklahoma, South Dakota, Tennessee, Texas, Utah, Vermont, Virginia, West Virginia, Wisconsin.

Associate—Colorado, New York, North Carolina, Pennsylvania.

Any information desired about reciprocal registration may be secured from H. C. Christensen, Secretary N. A. B. P., No. 150 Bowen Avenue, Chicago, Illinois.

## THE STUDY OF THE HISTORY OF PHARMACY BY STUDENTS OF PHARMACY AT AMERICAN INSTITUTIONS OF LEARNING.\*

---

EDWARD KREMERS.

---

1. The object of the course which has been given in alternate academic years for a number of years past is indicated in the following Prefatory Note to the Bibliographic Guide to the history of pharmacy which has been prepared first of all for his own students by the writer.

"As the title indicates, this brochure makes no pretense at being a complete bibliography to the history of pharmacy, much less does it presume to be a history of pharmacy. The sad fact is that we have no real history of pharmacy, indeed never have had one. However, we have a number of excellent historical treatises on pharmacy, a literature that has made excellent progress during the past two decades. Unfortunately, most of these treatises are not available to the average American pharmacist or student of pharmacy because of the foreign languages in which they have been written.

"Appreciating the broadening effect which even a cursory study of the history of pharmacy by the pharmacy student must have on his necessarily technical course of education, the writer has always sought to interest his students in the evolution of their calling. Some years ago this endeavor took on the form of weekly lectures which, so far as possible were illustrated by lantern slides. In order that the impression thus produced might be more lasting, these lectures have been supplemented by topics, some of which enabled the student to acquaint himself with important details that were, of necessity, omitted from the general survey of the lecture. This topic work also necessitated some acquaintance, on the part of the student, with the books available in the university library. Synoptical bibliographic sheets resulted as a practical expediency, and from these the present bibliographic guide. It is the hope of the writer, that in their present form these notes may prove of use not only to his own students, but also to some of his colleagues who appreciate the importance of historical study of the natural sciences by professional students."

*Scope of the Course:* Our pharmacy courses being already overcrowded on the side of technical information, but little time is left for such a course as this. One meeting a week, though for both semesters, necessarily implies great restriction. Such a course must of necessity be very general and avoid all detail that is not essential to illustrate the general principles that should be emphasized.

For reasons that become apparent by reference to the brief chapter on Classification of the Guide, the history of pharmacy is taught as an aspect of the history of civilization. Hence the course of following the periods of general history is followed. In each period only such countries are selected as teach a special lesson. Thus, for the period of antiquity, Egypt, Greece and Rome must suffice; for the middle ages, the Arabians. Of the modern period, Italy and France are selected as typical Romance countries; Germany and England as typical Germanic countries.

---

\* Abstract of paper read before the Historical Section at the Detroit Meeting of the A. Ph. A.

The first semester having been given to the study of the development of pharmacy in the old world, the second semester is devoted to the study of pharmaceutical history in the United States. The earlier developments of pharmacy in this country are traced back to the institutions of France and England, the later developments to those of Germany introduced during the second half of the nineteenth century.

In addition to these general considerations, special subjects such as pharmaceutical economics, organizations, education, etc., are studied in connection with these special chapters of the history of the United States, but in each case the beginnings are traced back to their European origin. This affords an opportunity to review some of the general aspects in their application to those special topics. Pedagogically, this is important, particularly since the line of thought involved is rather foreign to students pursuing courses that are almost exclusively scientific and technical.

*Methods of Instruction:*—In a course such as the one outlined, which of necessity belongs to the inspirational rather than the informational type, the lecture naturally is the dominant feature. Its object is not so much to impart fragments of information about this or that which may be directly useful to the future pharmaceutical practitioner. Its principal object is to cause the student to forget, for the moment, his chemistry and botany and to think of himself as a member of a calling, which, in one form or another, has served mankind since the beginning of civilization, and which, no doubt, will survive the storm and stress of the present and continue to serve mankind in the future. If history in general, is or should be the lamp by which our feet are guided, the history of pharmacy as a calling, rather than the history of a certain galenic with its quaint synonymy, ought to teach the prospective pharmacy student more of real value than the imperfect appreciation of chemical laws or the memorizing of doses, however, important both may be.

A lecture course of this sort, no matter how perfect the lecture or how inspiring the lecturer, is apt to induce superficiality unless supplemented by more substantial mental exercise. The topic is as essential as the lecture and when properly conducted will teach even the average American student that his fear of all that is foreign is rather foolish. There is no reason why the student should not learn directly from Scribonius Largus what constituted the *materia medica* of the ancients. From the British Encyclopedia he may get a general notion of the closed corporation, the Guild, and later the college. From similar general sources he may learn about the system of concessions, both real and personal. With the aid of an outline map of Italy, he may be taught to acquire a better understanding of local pharmacopœias, invariably the precursors of the recent modern pharmacopœias, and the close relationship between this class of pharmaceutical literature and the political divisions of humanity into states and nations. In like manner, outline maps of the United States will enable him to trace for himself the development of state associations and state legislation in this country. Moreover, weekly topics may be so assigned in the course of the two semesters, that the student is compelled to acquaint himself personally with at least those sources of historical information written in the English language.

With the modern facilities for supplementing the spoken word by visual instruction, a course of this kind would not be complete without lantern slides or similar means. Much of that which the teacher imparts in his lectures, is largely foreign to the mode of thinking of the average student concerned. The eye must come to the aid of the ear, not only to arouse the interest but to cause the spoken word to be truly understood and appreciated. The material available for this purpose is as considerable as some of it is choice, but it is not readily available even in our larger pharmaceutical libraries. While the money factor involved is by no means prohibitive, it requires love of the subject and patience to bring together a good working collection.

In connection with the reading of this paper an assortment of the different kinds of slides available was shown with the aid of a lantern kindly loaned for this purpose by Parke, Davis & Co., and operated by a member of their scientific staff.

The following slides were shown:—

#### A. PERSONS OF SPECIAL INTEREST TO THE HISTORY OF PHARMACY.

Geber teaching chemistry.  
Rhases in his laboratory.  
Paracelsus.  
Lemery.  
Scheele monument.  
Latin terms used by Scheele.  
La soeur apothicaire Pierrette Monnet.  
Joseph Pelletier.  
Joseph Bienaimé Caventou.  
Das Liebig Denkmal in Giessen.  
A. B. Prescott.  
Chas. Rice.

#### B. THE EVOLUTION OF THE APOTHECARY SHOP.

Facade of a Pompeian house.  
Floor plan of store in Pompeii.  
A store for the sale of food stuff (Pompeii).  
Dispensary of the monastery Muri (Switzerland).  
Hospital pharmacy, Dijon (France).  
An itinerant drug seller (15th Century, England).  
*Pharmacie Analaise* of comcimin (Antwerp, Belgium).  
*L'apicere de villave* by G. Don.  
Tenier: Chem. Laboratory (Dresden Art Gallery).  
*Apothekerkucche des Apothekers*, d'Villy (National Museum, Amsterdam).  
Apothecary shop (From *Hortus sanitatis*).  
Apothecary shop (From J. Amman).  
*Apotheke zum goldenen Loetzen*.  
*Apotheke* in Heppenheim.  
*Hochzeitshaus*, Hamelin (Sertmuer).  
Floor plan of *Farmacia Serravalle*.  
Copenhagen. Environs of Kong Salmons.  
Apothet.  
Scheele's *Apotheke* in Koeping (Sweden).  
An apothecary's shop (15th Century).  
Chemist, from "Book of Shops".  
S. A. D. Sheppard's pharmacy, Boston, Mass.  
L. A. Seltzer's (Chaumont) pharmacy, Detroit.  
*Arzneischrank*, (Germanic Museum).

#### C. MATERIA PHARMACEUTICA.

Distillation of mercury, sublimation of mercury.  
Symbol for sulphur, distillation of sulphur.  
Symbol for vitriol, preparation of vitriol.  
Symbol for salt, preparation of salt (16th Century).  
Scratching of poppy head (India).  
Opium Saloon (Shanghai).  
Pern balsam.  
Gutta percha.

#### D. PHARMACEUTICAL APPARATUS.

Balance: *Silphionhandel*.  
Balance: Roman *Schwellwaage*.  
Balance: 16th Century.  
Chest from Pyx Chapel.  
Roman perfume bottles, *unguentaria*.  
*Unguentaria*, etc.  
Glass ware.  
Glass ware.  
*Mensa ponderaria*.  
Mill for grinding olives.  
Oil press (Herculaneum).  
Expressing olive oil (Stradams).  
Still with barrel condenser.  
Apparatus described in Adam Lonicer's Distilling Book.

#### E. MISCELLANY.

"Oldest prescription".  
Papyrus harvest, plays and wine harvest.  
Scribes with role and pallet.  
"The oldest prescription known".  
Formula for medicament to drive away witches.  
Apprentice's certificate 1742.  
Specimen of practical examinations as master apothecary (France).  
Pharmaceutical pots.  
The apothecary of "M. de Pourceaugnac" by Moliere.  
Coat of arms of Paris Guild of Apothecaries.  
Book plate of Pharm. Soc. of Switzerland.

## Editorial

ERNEST C. MARSHALL, Acting Editor.....63 Clinton Building, Columbus, Ohio

### THE PHARMACIST AND THE LAW.

“CALL you that backing of your friends? a plague on such a backing,” was the protest of bluff Jack Falstaff to Prince Hal, and one is tempted to sympathize with him and cry out in protest, “God save me from my friends,” as he reads the further suggested effort to curb and restrict the already overburdened drug-trade, as embodied in the model law proposed to supplement the Harrison Bill by Messrs. Beal, Freericks and Craig.

Have we not enough law in the Harrison Bill to satisfy any reasonable person? Is it necessary to pile Pelion on Ossa; to add law after law in further effort to declare the members of our profession, enemies to all that is good; panderers to all that is vicious, and willing instruments in the destruction of society, to protect which from their attack, wall after wall of law must be built up?

Out upon such an effort. We have enough to bear, in the Harrison Law, which every good citizen earnestly desires may accomplish much good,—the good results that are postulated, without adding more and more to our burden at the suggestion of the lawyer members of our craft.

Of all the professions in this unhappy world, there is none which brings more trouble to it than that of the law, and the less our profession has to do with drug-gist-lawyers the better for it.

From the days of Jonadab, “a very subtle man,” who gave such foul advice to Amnon, mankind has been cursed by lawyers. Lord Chief Justice Brougham, being asked to define “a lawyer,” said “a lawyer is a learned gentleman who rescues your estate from your enemies and keeps it himself.” Those who have been charmed with the inimitable sea-tales of Marryat may remember that the most troublesome man on a ship was “a sea-lawyer,” and we are tempted to cry out, “Oh, Lord, Lord, save us from our pharmacist-lawyers,” for there is a limit to patience and the limit seems to have been reached. The tendency of lawyers is to look solely to laws as a bulwark of defence against all ills. They have no faith or trust in the inherent goodness of mankind, and by this lack of trust they do injury to all, the state and the individual citizen. Chief Justice Marshall is said by many to have done incalculable harm to this country by his construction of the Constitution, and the wrongs wrought by pettifogging attorneys have been prolific subjects for the author and dramatist, and few of us but know of some instance of their baneful deeds. It may be said, without much fear of question, that no class of men have been so dangerous, so pernicious to organized society, so subversive of all that is good in life as the legal fraternity.

Let us have done with law and lawyers for the present. Let us see what good there is, if any there exist, in the Harrison Law. Let us strive earnestly to eradicate the danger to our civilization which its exponents declared imminent. But

for Heaven's sake, let us not attempt to add more and still more law to that, until we observe its operation and effects.

"We must not make a scarecrow of the law,  
Setting it up to fright the birds of prey;  
But let it keep one shape, 'till custom make it  
Our ward and not our terror."

E. C. M.

### WASHINGTON PHARMACY LAW.

THE law proposed in the State of Washington (H. B. No. 135) to regulate the practice of pharmacy seems to be one most excellent, and it contains one feature which might well be copied by all states which suffer from the evils of itinerant vending.

Some of the plans proposed to control or regulate this evil might be well-termed bills to legalize itinerant vending instead of bills to control it, for they are so worded as to legitimize the practice even though they impose some financial restrictions. But in the case of the Washington law the framers of the bill have attacked the evil directly. Sect. 14 of the proposed bill is as follows:—

"It shall be unlawful for any itinerant vender, peddler or any person unless he be a registered pharmacist or registered assistant pharmacist in the State of Washington to sell or offer for sale any medicine, drug, nostrum, ointment, preparation and appliance for the treatment of disease, injury or deformity."

The salutary effect of this section is somewhat, if not entirely nullified however by Section 29 of the bill which allows unrestricted selling of "proprietary medicines or medicines in sealed packages" by any one without restriction as to place or qualification. While a man who has a store is required to obtain a license from the State Board of Pharmacy, any person can sell the same goods from a basket or wagon without such license. Thus, under this law, it would appear that while a person having a real or fancied ground for action against the seller of such medicines, could reach a man with an establishment which was properly licensed, he might, and probably would, find it impossible to reach a person without such establishment.

Some means should be devised by which the public could be protected in such cases.

To allow persons who may be entirely unqualified and who may never be seen again after selling the medicine, to sell drugs for the cure of disease without restriction, while those with permanent establishments are only allowed to sell the same goods when licensed, seems inconsistent.

E. C. M.

## GEORGE FREDERIC HOLMES MARKOE.

Professor Markoe was born in Valparaiso, Chili, in 1840. He was a posthumous child and spent the first ten years of his life in Chili with his mother's family. In 1850, his grandfather Markoe of Salem, Massachusetts, desired him brought to that city and the child of ten found many changes, most of them hard to bear, in the transition from the southern to the northern hemisphere. He made for himself, however, a good record at the Phillips Grammar School of Salem, and after his graduation was apprenticed in 1857 to Mr. James Emerton, a Salem pharmacist. Here he followed a course of study outlined by Prof. William Proctor, and upon the Salem Fells began the study of botany, which in later years brought him into close friendship with Prof. Asa Gray of Harvard University.

In 1861 he came to Boston and entered the employ of Mr. Charles T. Carney, whom, ever afterwards, he regarded as "My Master," and for whose ability and integrity he always retained the highest admiration.

In 1863 he entered the store of Joseph T. Brown, one of the principal pharmacists of Boston, and for eleven years was associated with that firm, the last three years as a partner. In 1873 he became proprietor of the store established by them in Roxbury, a part of Boston, in which suburb he resided for seventeen years, during which time he did much active work along chemical lines. He was a pioneer in manufacturing pharmacy, doing much in the making of chemicals and chemical solutions. Here his famous process for the manufacture of phosphoric acid by the action of bromine and nitric acid on phosphorus was evolved. He also did much analytical work and was consulted by many for counsel in practical methods for improvements in chemical processes. He possessed great mechanical ingenuity which served him well when in need of apparatus, of which for years his stock was small.

In 1890 he retired from the retail drug business and devoted himself to work in the Burnett laboratories and to teaching.

His early difficulties in the line of study, led him to sympathize with the apprentice of few opportunities and opened the way to what was undoubtedly the best effort of his life; the establishment of instruction by the Massachusetts College of Pharmacy, which before 1866 was an incorporated body, but not a teaching institution. In 1867 he delivered in a little room on Boylston Street, a series of free lectures on Pharmacy and Chemistry, and from that time, for nearly thirty years, he served as a Professor of his beloved College of Pharmacy, which he was proud and happy to see grow into a strong and influential institution from his small beginning. In 1870 he founded the Alumni Association, and served as its first President. No student ever came under his care who could not at any time command his help and sympathy and in the latter part of his life the recognition of his kindly and helpful assistance by many of these, was to him a source of endless happiness.

From 1873 to 1879, he was Instructor of Materia Medica in the Harvard Medical School. For nearly three decades he served on the Revision Committee of the U. S. Pharmacopœia. He was affiliated in many circles allied to pharmacy; was President of the American Pharmaceutical Association in 1875-76, and was an active member of the Boston Scientific Society, the Horticultural Society, Society of Arts, Massachusetts Pharmaceutical Association, Boston Druggists' Association, a Fellow of the American Association for the Advancement of Science, an honorary member of the British Pharmaceutical Conference and of the Royal Pharmaceutical Society of Brussels. In 1891 Dartmouth College conferred upon him the honorary degree of Master of Arts.

He was twice married. By his first wife, Ellen G. Jenness, he reared one son, George Berger; and by his second wife Louise, granddaughter of Sir Emanuel Moore, he was blessed with one daughter, Llannd Ellis, the secretary of the large department store of E. A. Filene & Sons, of Boston, Mass.

He passed into the "Great Unknown" in September, 1896, leaving behind him the love and regard of all who knew him best, and who cherished his kindly and genial nature.

## Papers Presented to Local Branches

### MINERAL WATERS.\*

THEIR ORIGIN, INTRODUCTION, ANALYSES AND ARTIFICIAL REPRODUCTION.

JULIUS GREYER.

Water, an inorganic body and a compound of a definite composition, Hydrogen monoxid, is itself a mineral. It is a universal solvent. An absolutely pure water is the product of the laboratory alone. From a strictly scientific standpoint we could consider all waters as mineral waters. The definition as to what should be termed a mineral water will therefore depend largely upon the point of view; that of the chemist differing from that of the physician or that of the layman.

The term mineral water as commonly used has been applied to waters containing an appreciable quantity of minerals. The definition of what constitutes a mineral water, given long ago by Doubený, perhaps covers the ground as well as any other. He says:—"The term mineral water in its most extended sense, comprises every modification existing in nature of that universally diffused fluid whether considered with reference to its sensible properties or to its action upon life."

From the therapeutic standpoint, a mineral water is any water which may alter in any way the physiologic functioning of the human system, no matter how feebly mineralized the water may be,—or it is any water which, by its inorganic solid or gaseous constituents, exhibits or possesses medicinal virtues.

Although some waters are much lighter in mineral constituents than the ordinary potable waters of most localities, they are yet entitled to a consideration under the appellation "Mineral water," whether its medicinal virtues be due to the presence of some substance effective in small quantities, or its purity and thereby permitting large quantities of fluid to be used.

Wherever we go we find mineral springs, some of which issue quietly and peacefully from the earth, while others are forced to the surface with great violence, either steadily or at intervals, some ascend from the bottom of the sea or lakes or rivers, others appear thousands of feet above the level of the ocean. Some issue from the earth having a temperature near freezing, others near the boiling point, some after reaching the surface of the earth are so heavily laden with matter as to cause crystalline, calcareous and other deposits or precipitations.

The origin and nature of springs depend beyond any doubt upon a leaching process occurring under the influence of atmospheric precipitations, rain water. As water passes through rocks or mineral deposits, it continually leaches out all

\* Read before Cincinnati Branch, January 12, 1915.

soluble substances on its way to the interior of the earth, until it reaches the impenetrable layers of clay. Here it meets with other waters which may have traveled great distances through other channels or arteries, having leached other and different strata and consequently dissolved other and different substances. These waters then by hydraulic action or by the pressure of gas as the case may be, are again forced upward, passing through possible new and various strata, and again they may become active, interchanging and possibly again depositing new precipitations of matters which have become insoluble. When finally the water reaches the surface of the earth it either emanates in a quiet peaceful flow or is driven upwards with more or less, and often very great, force. In the formation of mineral waters the vast number of combinations and their operative factors always correspond with the variety in composition of natural mineral waters.

The physiological properties of mineral springs, although replete with wonders to the uneducated, have attracted the attention of scientific men from an early period. Supernatural properties have been ascribed to springs; strange stories propounded regarding their origin and tales and fables were spread regarding their wonderful powers and miraculous effects. Even to this day we find proprietors or owners of springs advertising and claiming supernatural powers and properties for their waters, but, thanks to advanced science, our Government now stops this whenever aware of such tactics.

To illustrate some of the ways of advertising I have a few of the most interesting labels and pamphlets with testimonials.

From a pamphlet of The Kentucky Carlsbad Springs Co., Dry Ridge, Kentucky, we read as follows:—

"The water cure is certainly the most acceptable way to take medicine. Any physician will tell you, after he sees the analysis of the Kentucky Carlsbad Water, that it contains every medicinal quality necessary for the cure of the diseases herein specified. We will take the albumen out of your water in three days. We will give relief of the most severe case of kidney trouble in one day and will absolutely cure any case in ten days. Stomach trouble will be relieved in twelve hours and we will guarantee it to cure any case in the world in ten days, if it has not become cancerous. Bladder trouble of any kind will be cured in ten days. It will cure any old sore by bathing in it two or three days, and if you have any catarrh, heat the water and douche it up the nose on the sore spots and in one week you will have no catarrh. It will cure any sore it comes in contact with and this is the reason it cures stomach and sore kidneys and bladder as it comes in contact with these organs."

The same Company publishes the following testimonial:—

"To whom this may concern:

I will say that I am seventy-six years old, and have had albumen in my urine for five or six years, so much so that a layer would form in the bottom of the chamber in which I urinated, but after a stay of five days at the Kentucky Carlsbad Springs my urine was perfectly clear and no signs of albumen could be seen. At the same time, I had my wife there, who had not walked for four years, and in seven days she was walking. I would sincerely recommend the water as wonderful and beyond what words could express."

I herewith present a label of the Partagas Lithia Spring Water. In the analysis made by C. T. M. Marsh and which is published on the label, no mention is made whatever of any lithia, but this does not prevent this concern to market the water under the name of "Partagas Lithia, The Autoerat of Waters."

Another label of The O. J. Ferris Springs, Plainville, Ohio, reads,—"Crystal Fountain Springs. Purest and best Table Water."

A label of The Isham's Springs of Life Company, San Diego, Calif., reads as follows:—

"Isham's California Waters of Life. The World's Wonder. They possess miraculous power to destroy disease and actually rejuvenate humanity by dissolving and evacuating calcareous old age matter and microbes. The worst forms of costiveness, kidney, stomach, skin troubles, even cancers and gall-stones yield to its marvelous power. Persons troubled with obesity or emaciated victims of excessive use of liquor, tobacco and opium, involuntarily return to a normal, healthy condition and grow strong without a drooping of the spirit. With the new life comes the bright eye, elastic step and a new growth of luxuriant hair."

Another type of existing mineral waters which I have not yet mentioned, are those collected from wells which are dug. To this class belong the various Hungarian Bitter Waters, the Hunyadi, Apenta and others. Hunyadi Janos, for instance, is collected in the Kehlenfeld, consisting of a bed of marl lying in a flat valley between the Adlerberge or mountains. By digging holes, say from 10 to 20 feet deep, the water collects in these wells in a more or less concentrated form, which is dependent upon atmospheric conditions and precipitations. From these wells Hunyadi Janos is pumped into large cisterns and mixed with water from a well yielding a lighter or heavier concentration, until it shows a certain specific gravity, and in this way it is claimed by the proprietors, the Saxlehners, Hunyadi Janos is always of the same composition, a claim which may be characteristically correct, but it is certainly *not* so chemically. So here we are, Hunyadi Janos to-day is a mixture of about 128 or more wells, owned by the Saxlehners, and among which are those which in former years were marketed by their owners under such names as Hunyadi Arpad, Mielos, Lajos, Lazlo, Joseph, Sandor, etc., etc. They have mostly been acquired since by purchase or otherwise by Saxlehner with the intention of monopolizing the Hungarian Bitter Water Industry.

The success with which a great many mineral water concerns have met and whose waters have become renowned and are marketed all over the world, has been an inducement to many a man owning a spring, the water of which may have exhibited one or another peculiarity, effect or character, to start a spring company, bottle the water and flood the market with their output, advertising matter, testimonials, etc., etc., but the greater majority soon pass into oblivion. You probably remember Ballardvale, Tuckahoe, Navahoe, all lithia waters which have recently died a natural death and upon which large sums of money have been expended. There are thousands more like them.

For a proper and effective introduction of a mineral water it is necessary to ascertain its composition by analysis. This establishes its nature, virtue, character and possible therapeutic value. In fact all mineral waters are to-day introduced by bringing the results of the analysis to the attention of the medical profession. Proper medical application and careful observation afterwards, will then reveal the true medicinal value of same.

What druggist has not met the man who came to him, bottle in hand containing water from the spring of his farm or his ranch? According to his story, he thinks himself in the possession of a veritable fountain of youth, the water having effected some of the most remarkable and miraculous cures and is known to have saved the lives of quite a few who had been afflicted with some incurable disease. If nothing more, it certainly cures kidney and bladder troubles.

Our man, I will call him farmer, like all farmers with a keen eye for money,

already imagines himself the president of a large Spring Water Company; he thinks of the bottling as well as of the advertising of his already renowned water, but more so of the profits which he might be able to make at so much per gallon and costing nothing.

Our farmer having gathered advices from others, is already aware of the fact that to introduce his spring water to physicians, an analysis is of vital importance, then, too, it also impresses the public most favorably and, of course, it is a very able judge of analyses.

The first step has been taken by Mr. Farmer to procure a chemical analysis. The chemist, in many instances of doubtful ability, for the sum of \$10 or \$20, furnishes the required article, and this is to some extent an explanation why we come across analyses of waters which are absolutely unreliable and some even ridiculous.

In looking up analyses of one and the same water, but made by different chemists, we often notice great differences in their results. One chemist finds a water to contain ten or twelve different salts while the other reports but four or five, yet both chemists may be right, both may have found the same quantities and kinds of acids and bases. The only difference I may say is, that the one chemist has apparently furnished more for the money than the other.

You all know that, in analyzing, we ascertain the kind and quantities of the acids and bases contained in the solution, in our case this being the mineral water in question.

Now then, say both chemists have found the same acids and the same bases in exactly the same quantities, the one may have followed an accepted norm in building up the combinations, while the other combined the acids and bases found, to suit his fancy or in some sort of a haphazard way. By chemists having followed their fancies more than their reasons, the grossest mistakes, yes, absolute impossibilities, regarding the nature of mineral waters have occurred.

It is a difficult matter to compare the work of two chemists and their analyses of one and the same water without laborious re-calculation.

Only of recent years, advanced chemists have adopted a certain norm in combining the results of their analyses of mineral waters, this norm was originated and used by Bunsen, Fresenius and others.

An effort is now being made and conducted jointly by committees of the American Chemical Society, the American Public Health Association and the Association of Official Agricultural Chemists to formulate standard methods for the computations of water analyses.

The statement of an analysis in hypothetical combinations, is evidently a mixture of fact and opinion, ordinary chemical tests reveal but little regarding the chemical composition of mineral waters, therefore the exact amounts of the different salts in solution in a mineral water are largely conjectural; although salts are present, it is a mathematical impossibility to apportion correctly the found quantities of acids to those of the bases, or *vice versa*.

This lack of definite information enables one to follow pretty much his own imagination, and there are many opinions as to how the acids and bases should be combined.

We know that one acid has by far a greater affinity for a certain base than

another. We also know that in the formation of salts, whenever two substances or two solutions of salts are mixed and that whenever such two solutions contain such salts as are liable to form an insoluble compound or a salt which is insoluble, such a salt is formed absolutely.

A solution of Barium Chloride and a solution of Sodium Sulphate when mixed will always form Sodium Chloride, the soluble, and Barium Sulphate, the insoluble salt, and this totally so, if the solutions are mixed in proper molecular proportions.

Knowing this, is it not reasonable, therefore, that as solutions, (mineral waters in this case) contain different acids and bases, that we should assume that the latter are combined in the solution in the ratio of their solubility in water?

A mineral water just emanated, has left all insoluble substances in the ground. In the course of its travel to the surface, it has undergone many changes; it has formed many precipitates and has left them behind. The chalk, gypsum and talcum beds found in nature are the results and the proofs of such ever-occurring precipitations.

Mineral waters, generally, come to the surface of the earth in the form of a clear, brilliant, sometimes bubbling and sparkling and sometimes foul-smelling solution and a "solution" is just what a mineral water is. Now then, is it not reasonable that,—since precipitates or matter which could not be held in solution by the water or which by interchange became insoluble and have been thrown out and left behind,—we assume that those salts least soluble in that solution or mineral water are ready next to also precipitate by the slightest physical change? It certainly is.

This is one of the reasons why Bunsen, Fresenius and other reputable chemists, in considering the results of their analyses, begin with the calculation of the least soluble substances or salts first, advancing to those whose solubility is greater and close with those most freely soluble in water.

In consequence of this the following approximate succession originates: Aluminum, Silica, Barium sulphate, Strontium sulphate, Ferrous carbonate, Manganous carbonate, Calcium sulphate, Calcium carbonate, etc., closing with those whose solubility is very great as, for instance, calcium chloride, sodium bromide, calcium iodide, etc.

Right here I want to mention the name of Dr. F. Raspe, a man who devoted almost a lifetime to the bringing of order out of the chaos of existing analyses of well-known mineral waters from all over the world. Raspe has re-calculated no less than twenty thousand analyses which means that now, these analyses can be compared intelligently, because the differences in the composition of the waters is clearly marked.

Dr. Raspe undertook this enormous task mainly in the interest of the manufacturers of artificial mineral waters.

Like everything else in this world, so has the manufacture of artificial mineral water its history.

Pliny, more than 2000 years ago, observed that "Waters are of practically the same nature as the earth through which they pass."

The first experiments to artificially reproduce a mineral water are said to have been undertaken by Thurneiser in the year 1500. This was before the discovery

of carbonic acid by Van Helmont, 1624, but his results were as poor as those of R. Hoffmann in 1685 and of those of Geoffroy in 1720.

In 1750, Venel, a physician of Montpellier, proposed the dissolving of carbonate of soda in hydrochloric acid and water in a closed bottle and by this method to impregnate the resultant solution of sodium chloride with carbonic acid gas. Finally in 1767, Bewley showed a way to produce carbonic acid gas in a separate apparatus by which he was enabled to impregnate water contained in another vessel with this gas, a method which was soon improved and followed by Priestley, 1772, Lavoisier, 1773, Noll, 1775, Magellan, Corvinus, VanChaulnes and Tobern Bergman, 1777, and others. Bergman, in 1774, had already set up the principle that if to water be added the ingredients found by analysis in proper form and quantities, a water identical with the natural water should result, and it was he, who pointed out the fact that the refreshing taste and exhilarating effects of a sparkling or effervescing water is due to the carbonic acid gas dissolved in it.

After Bergman, the interest in artificial mineral waters became very generally recognized in France, England, Switzerland and Germany.

In 1780, Duchany in Paris published the first book on the manufacture of artificial mineral waters.

In 1787, Meyer of Stettin, Germany, manufactured carbonated waters in large quantities.

In 1788, Paul & Gosse in Geneva constructed the first intermittent mineral-water apparatus.

In 1798, the same Paul founded the first mineral-water factory in Paris, and Pierre Fiquir in Marseilles in 1800, and after these followed Schweppe in London, Fries in Regensburg, etc.

Artificial mineral waters in those times were yet imperfect products, because chemical science had not reached its present knowledge and the apparatus were of very primitive construction. These were also the main causes for artificial waters being discredited and the ideas advanced that natural waters were peculiar products and of a nature which could not be artificially reproduced.

Within the past seventy-five years, however, it has been possible to produce artificial mineral waters of absolute perfection. Bergman, Berzelius, Bischof and Struve had pointed out that the composition of natural mineral waters depends upon the amount of carbonic acid and other gases which are dissolved in the water and upon the rocks and strata which they permeate and upon which it acts, and it was Struve who proved this by direct experiment.

Struve selected for his first experiment the acidulous alkaline Joseph Spring of Bilin, Bohemia. He filled a metallic cylinder of about six feet in length with a mixture of powdered quartz sand and klinckstone both of which he took from the ground of the Donnersberg in the immediate neighborhood of Bilin, and subjected this to the action of carbonated water under pressure, he thereby succeeded in producing an artificial water identical in composition with the Joseph Spring.

Struve followed this experiment in a like manner in producing artificial Carlsbad and Friedrichshall, both of which Faraday and Liebig pronounced identical in chemical composition and physiological and therapeutic action with the respective natural waters of these springs.

It is an undeniable fact that the honor to have by his efforts overcome all technical difficulties and to have placed that which had previously been considered unattainable, upon a scientific basis, belongs to Dr. Struve. It was he to whom thanks are due for having produced the first identical reproductions of mineral waters correct in chemical composition, in physical properties and in therapeutic effects and he is therefore deservedly called the father of artificial mineral waters.

Another fact which I want to mention, in connection with the introduction by him of his scientifically prepared mineral waters, is that his efforts accomplished most towards revealing the actual nature of mineral springs and their waters, and that, through his knowledge and scrutiny, many spring and natural mineral waters have greatly profited, inasmuch as their real therapeutic value and their proper application became known among physicians as well as to the public.

Friedrich Adolph Struve, Doctor of Medicine and owner of the Salomonis Apothecary in Dresden, Germany, was born May 9, 1781. After devoting the greater part of his life to his studies in the interests of both the nature of mineral waters and that of the manufacture of artificial mineral waters, he died September 29, 1840.

Struve's first artificial mineral-water institute was opened in Dresden in 1820; this was followed by one in Leipzig, another in 1823 in Berlin, one in Brighton, England, in 1825, and others in Germany, England and Russia, all of which were under his direction and that of his sons. Since then the number of factories increased rapidly, so that in 1877 there had been over 700 of them established in Germany alone.

In America the manufacture of scientifically prepared mineral waters such as are true reproductions of the respective natural springs, is still in a much neglected condition. Very many manufacturers, even at the present time, are using as their unit of measure, in compounding their waters, an ordinary shovel. Others which are more progressive and who at least try to be honest, buy mixtures of so-called mineral water salts, under the various names of springs from manufacturers or supply houses, which, however, at most, furnish but extremely poor results for such salts cannot claim to be anything near to being true representatives of natural springs. It is impossible to compound or to produce true artificial mineral waters from any mixture of water-soluble salts, because such waters contain also substances which are ordinarily insoluble in the form of a salt.

The credit of being the originator of scientifically produced artificial mineral waters in America, belongs to Dr. Carl H. Schultz, who started their manufacture in New York in 1862. Schultz was followed by Dr. Euno Sander of St. Louis and W. T. Wagner's Sons of Cincinnati. These establishments have chemists to compound their waters and have made a name for themselves and their products, and I express the hope that inasmuch as there are very great opportunities outside of New York, St. Louis and Cincinnati, others may soon follow in the uplift of this industry.

It is the duty of a manufacturer of artificial mineral waters to compound his waters in such a manner that when his product is finished, it will conform exactly to the analysis of the respective spring. All and even the minutest quantities of

the various salts shown in the analysis of a water should be taken into consideration by him and should be one of the component parts of his product; nothing should be left out, even if it be considered superfluous or inert.

It is true and it cannot be denied that the salts in a natural mineral water are not always combined exactly in the manner as stated by chemists in their analyses, but this has no bearing whatever on the product of a compounder of an artificial mineral water.

It is entirely immaterial, for instance, whether a chemist or analyst, in his analysis, denotes one molecule sodium sulphate ( $\text{Na}_2\text{SO}_4$ ) and two molecules potassium chloride ( $2\text{KCl}$ ), or one molecule potassium sulphate ( $\text{K}_2\text{SO}_4$ ), and two molecules sodium chloride ( $2\text{NaCl}$ ). It is also immaterial whether a solution, or in this case a mineral water, contains these substances as such, meaning as actual salts or as molecular fragments (ions). The artificial product, whether made by dissolving either one molecule sodium sulphate ( $\text{Na}_2\text{SO}_4$ ) and two molecules potassium chloride ( $2\text{KCl}$ ), or by dissolving one molecule potassium sulphate ( $\text{K}_2\text{SO}_4$ ) and two molecules sodium chloride ( $\text{NaCl}$ ) in water, will contain the same ingredients, the potassium and the sodium as bases and the hydrochloric and sulphuric acid, as acids, in precisely the same quantities and form or forms as in the natural product because they are bound to follow and do follow the same natural laws in one, the natural solution (the mineral water), as in the other, the artificial solution.

Another example:—If we make a solution of proper amounts (the molecular weight) of potassium bromide ( $\text{K Br}$ ) and sodium chloride ( $\text{NaCl}$ ), in distilled water, we will get the same result or exactly the same product as by dissolving (the molecular weight) of sodium bromide ( $\text{Na Br}$ ) and potassium chloride ( $\text{KCl}$ ) in an equal amount of distilled water. Both solutions will have the same action, therapeutically, physically and chemically.

The natural-water men who have been fighting all these years and have tried their best to discredit scientifically-prepared mineral waters, have, to this day, failed to prove the slightest physical, chemical or therapeutical differences between the natural solution of salts, the natural mineral-water, and the scientifically-prepared solution of salts, the artificial mineral-water.

In the manufacture of true artificial mineral waters every ingredient is added to the water in a soluble form, all precipitates which are formed by the mixing of the solutions, are redissolved by and under the presence and pressure of carbonic acid gas.

If the various acids and bases contained in either, the natural and the artificial solutions, agree quantitatively and qualitatively, then as said before Nature will absolutely follow or apply the same law to one as it will and does to the other. Both solutions have been proven to and do act alike physically, therapeutically, chemically and electrochemically; they are absolutely identical in every sense of the word and this in spite of all assertions to the contrary as made by those interested and more especially, financially interested in the natural mineral-water industry.

The following illustration given by Dr. Raspe shows what may, at first sight, appear to be the analyses of three entirely different products or composition, or the analyses of three waters entirely different in composition.

These analyses do not seem to agree in the slightest, yet they have exactly the same value.

	10000 Parts		
	A	B	C
Sodium Chloride .....	3.297	5.846	.....
Calcium Chloride .....	2.418	.....	5.546
Sodium Sulphate .....	1.035	.....	1.775
Calcium Sulphate .....	0.708	1.700	.....
Sodium Bicarbonate .....	2.178	.....	5.625
Calcium Bicarbonate .....	3.310	5.400	.....
	<hr/> 12.916	<hr/> 12.946	<hr/> 12.916

A. Represents an analysis and an application of acids to bases very generally found, in which the chemist has followed no particular norm, but simply his own fancy. With a greater number of elements, the complication would naturally be greatly increased.

B. Represents the same analysis as does A., but in another form, that of the so-called Normal Analysis as adopted by Dr. Raspe and who follows, with but few exceptions, the principles of Bunsen, Fresenius and others.

C. Represents a re-calculation by Raspe in the soluble form, the form which is necessary for the manufacturer of mineral waters.

If you will take the trouble to calculate the quantities of the elements or if you like, the acids and bases contained in either A., B. and C., you will find them to agree perfectly.

It is a fact also that, if you will compound a solution in water so as to contain in 10,000 parts, the amounts of elements, or of acids and bases or their equals in salts, in proper quantities, as given in either A., B. or C., you are bound to get the same results, because the natural laws of changes and interchanges of the ions or molecules in solution will apply themselves to the one solution as to the other. It is experimentally proven as mentioned before, that salt solutions, formed by different salts but corresponding to the same ionic table, have the same physical properties.

Many controversies have been carried on between those balneologists who speak in favor of natural mineral waters and who claim a superiority for them, and those scientific men who declare themselves in favor of and who prefer and recommend the use of scientifically-prepared artificial mineral waters; especially does this preference apply to the bottled and shipped natural waters as found in the market, which often, are quite aged before they reach the consumer.

It might be interesting to you to listen to the words of a few authoritative men opposing the contentions of those who, in their arguments against artificial mineral waters, claim that man cannot produce anything new in nature by artificial means nor produce artificially such a thing as an artificial mineral water. In doing this I wish to call your attention to the fact that the opponents of artificial waters lay special stress upon the unknown substances and the hidden powers contained in natural waters and which they say chemists to this date have not been able to detect.

Dr. Wachter (Heidelberg) says:—"Does not man by use of reason and choice selection breed animals, does he not bring thousands of plants in close contact with each other for the production of a new heretofore unknown species? Yet no

one will assert that he is the real creator of the newly-acquired result of the cross-breed. . . . As every one may know, fluid water is composed of two gaseous elements, oxygen and hydrogen, a mixture of which gases can be brought to unite by but a weak electrical discharge into a fluid form,—into water. Now, no one will assert that this water, seemingly produced by man (the artificial), is different from the atmospheric or terrestrial (the natural water). No one will doubt that it is water at all because the coarsest reasonable conception will enable one to identify it as such."

Dr. Max Roloff of the University in Halle says:

"Wherever physical chemistry has been treated with knowledge and logics and has not been pressed into the service of water-advertisements (Brunnenrek-lame), there is not the slightest point to show a principle of physical or chemical difference between artificial and natural waters. . . . Has not the surrogate manufacturer just the same right to assert that his product surpasses the natural spring because it does not contain those harmful mysterious impurities? Further, I have never found that a spring was recommended because of the curative power of the unknown ingredients, the therapeutic effects were always founded upon the known and, in proven quantities, present salts and because of these quantities compared with similar springs. The balneologists then, do not themselves believe in the action of these mysterious matters, these only serve as an argument in fighting competition."

Prof. Carl Ernst Bock, of Leipzig, in speaking of artificial mineral water, says:—"Artificial mineral waters take the place of the natural mineral waters in every respect, although many physicians are prejudiced against the former."

Dr. W. Jaworski, Prof. int. med., University, Krakau, says:—"The scientific investigation so far has not been able to prove any specific properties in mineral waters which were not also possessed by the artificial solutions. Both salt solutions follow the same natural laws. The contrary assertions are spread for reasons of personal interests. . . . There is no proven difference to be found in the action of the artificial salt solutions and the mineral waters upon the system. The experimental investigations have not been able to prove a difference, but on the contrary, they have proven the identity in action of the natural and artificial salt solutions. . . . The natural mineral waters are crude products (*Medicamenta cruda*) of accidental composition, which, in modern therapeutics, may be placed among the many obsolete products of nature."

In conclusion, I, herewith, give another quotation from Dr. Wachter. . . . "The manufacturer has done his duty as soon as he proves that his artificial water agrees with the natural water in every way in chemical and physiological respects, and it is, as soon as he has fulfilled these conditions, a deep re-acting wrong, if physicians and laymen assert that a proven difference exists between the spring waters and that produced in the laboratory, while they are at the most entitled to say:—'It is possible that a difference exists, but that it is not detectable with our present analytical means,' and never was a physician in the position to maintain of an artificial water which fulfilled the requirements of a chemical analysis, that the artificially produced water has a different action upon the system than the natural, but you always hear them say, 'I take it for granted that they act different because they are not natural.' . . .

## RESTRICTIONS IN THE DISTRIBUTION OF POISONS.\*

---

CARL T. BUEHLER, PH. G.

---

There has been so much written and said about restrictions in the distribution of poisons, and yet, we seem to be at the starting-point. I think it is the duty of every pharmacist to take an active part in the operation of our pharmacy laws, and if they are not satisfactory, then we should decide what we want and all put our shoulders to the wheel and work until we get a pharmacy law that is of mutual benefit to the pharmacist and to the public.

The following paper contains only an individual opinion regarding the poison law, but I will be pleased to hear remarks and suggestions.

I am in favor of two schedules:—Schedule A, and schedule B. Schedule A, to contain a list of habit-forming drugs and abortifacients, their sale to be restricted to physicians' prescriptions only, and in no case should these prescriptions be re-filled without an order from the physician.

The physician should not be allowed to dispense in his office or elsewhere, any drug, chemical or preparation enumerated in Schedule A., but in all cases he should be required to write a prescription for them; this prescription to be filled by a licensed pharmacist.

To prohibit the pharmacist from the sale of habit-forming and abortifacient drugs, and to permit the physician to dispense them, does not put a stop to the evil. There is no more justice in this, than there would be for a mother who has two sons, to teach one that it is wrong to dance, and to make a dancing-teacher of the other. This would not stop dancing. Neither will the illegitimate sale of habit-forming and abortifacient drugs be stopped as long as a tight rein is held on one person and a loose rein on the other. A "dope fiend," as he is called may go to a drug-store to get some "dope," and be refused; then he goes to a dispensing physician who accommodates him. Who does the public blame for this sale? I will leave this question for you to answer.

Any physician doing business as a pharmacist, should not be permitted to fill the prescription he writes for a drug, chemical, or preparation enumerated in Schedule A., but at all times some other licensed pharmacist should do the compounding and dispensing.

*Schedule A.*:—Hydrocyanic Acid, Opium, and all preparations of opium containing more than two grains to the ounce; Morphine, all salts of morphine and all preparations of morphine, containing more than one-third grain to the ounce, with the exception of Dover's Powder; Cocaine, all salts of cocaine and all preparations of cocaine; Codeine, all salts of codeine and all preparations of codeine containing more than one-half grain to the ounce; Chloral Hydrate, all preparations of chloral hydrate; Heroin, all salts of heroin and all preparations of heroin; Beta-Eucaine, Beta-Eucaine Lactate; Ergot, Veratrum, Cotton-Root, Savin and all its preparations.

Nothing in Schedule A. should interfere in the treatment of emergency cases

---

\* Read before St. Louis Branch, November.

by physicians or the selling of any drugs, chemicals, or preparation by a pharmacist to physicians, or the sale among manufacturers, wholesale druggists and pharmacists, or the sale of hypodermic tablets to dentists, graduate nurses or nurses in training.

Schedule B. to contain a list of poisons not enumerated in Schedule A.

*Schedule B.*:—Aconite, Belladonna, Colchicum, Conium, Nux Vomica, Cantharides, Digitalis, Henbane, Cannabis Indica, Stramonium, Gelsemium, and their pharmaceutical preparations. Arsenic and its preparations. Mercury and its salts with the exception of Calomel. Zinc Sulphate, Cyanide of Potash, Oil of Bitter Almond, Croton Oil, Chloroform, Ether, Carbolic Acid, Oxalic Acid, Strychnine and its salts, Elixir Iron, Quinine and Strychnine, Potassium Hydroxide, Sodium Hydroxide, Paris Green, Spirit of Nitroglycerin, Wood Alcohol, Denatured Alcohol, Mineral Acids, Iodine and its preparations, Lead Acetate, Potassium Permanganate, Cresol and all preparations of Cresol, Silver Nitrate, Tartar Emetic, Oil Mustard, Bromine, Formaldehyde Solution more than two *per cent.* in strength.

All drugs enumerated in Schedule B. must be recorded in a poison register similar to our present Missouri law requirements for Schedule A. An entry should be made, stating the date and time of sale, name and address of purchaser, male or female, name and quantity of poison sold, the purpose for which it is supposed to be used and the name of the dispenser. The container should be labeled with the name of the article, the word "Poison," and the name and address of business of the seller. Such book should always be open for inspection to proper authorities, and the register to be preserved for at least five years after it has been filled. Nothing in this schedule should apply to the dispensing of poisons in not unusual quantities or doses, by the pharmacist upon the prescription of a physician or upon the prescription of a dentist for mouth washes. Nothing in this schedule should be so construed as to interfere in the sale among manufacturers, wholesale druggists, pharmacists, physicians and dentists.

Should the physician be allowed to dispense articles enumerated in Schedule B., provided he keeps a record similar to that of the pharmacist? Or, should he be allowed to dispense these poisons as he is doing to-day, without keeping a record and without labeling the container, stating the name of the poison or directions for its use?

In my opinion, as long as physicians are permitted to dispense, a practicing physician should be permitted to dispense to his patients any article enumerated in Schedule B., either alone or in a compound, by first making an entry in a book kept for that purpose, stating the date, name and address of the patient, name of poison, alone or in compound, quantity dispensed, quantity in each dose, number of doses. The container should contain the name of patient, directions how to be used, name and address of physician.

Schedules A. and B. have reference to original and broken packages, sealed and unsealed packages.

## Section on Practical Pharmacy and Dispensing

Papers Presented at the Sixty-Second Annual Convention

### SHOULD THE RETAIL DRUGGIST MANUFACTURE HIS OWN PREPARATIONS, OR BUY THEM?

CHARLES J. CLAYTON.

This is a problem that can be solved in almost as many ways as there are retail druggists, for the answer depends upon the conditions surrounding each one, who must decide for himself, according to those conditions.

To the true pharmacist, the making (the creating) of his own preparations is the breath of life, and he will, if necessary, sacrifice both time and profit to the gratification of his desire in this direction.

However, in this day and age, true pharmacy, unmixed with commercialism, is hard to find, and commercialism decrees that our preparations shall be produced at the lowest cost commensurate with first quality, and it may, and often does happen, that some one else can be employed to do many things for us more cheaply than we can do them ourselves. If then, we are justified in employing some one to do these things for us in our stores, where the facilities for good work are often lacking, may we not be equally justified in going a step farther by the employment of coöperative manufacturing enterprises, or the purchase of our preparations from some reliable manufacturing house? Surely, there would be nothing unethical in this, and it may well be that in many instances, by reason of the facilities that these houses have for securing the best qualities of crude drugs and for assaying the finished preparations, the latter would more nearly conform to the standards set by the authorities. Then, too, it has been my experience that a large proportion of drug clerks, — even though they may be registered and graduates in pharmacy, — to whom the manufacturing work in the store falls, are either incompetent or careless of results.

So, in order to be sure of good results, the employer must, in many instances, either do the work himself or exercise a close supervision over those who do.

Even in the case of such preparations as are almost universally made in the stores where they are sold, we are reminded occasionally of the need of supervision, the following instance occurring to me recently: During the temporary absence of my clerk, a relief man was employed, one who was registered, and who had conducted a store of his own for a number of years. He called my attention one morning to the fact that he had started to make some solution of Magnesium Citrate, saying that he did not know whether he was making it according to my way or not. On being asked if he had followed the U. S. P. formula, he said he didn't know: he had put in two ounces of magnesium carbonate and four ounces

of citric acid for six bottles. His attention was called to the fact that considerable more of these articles were needed to make it right, and he was asked if he had added the syrup and flavor, to which he replied, "No, what flavor do you use, Vanilla"?

He stated that he had found his formula in the last store that he had owned, and had been using it ever since, without a thought as to whether it conformed to the standards or not.

I have seen a percolation-process performed by pouring a menstruum repeatedly through a loosely-packed or entirely unpacked drug, and I have seen a finely-ground drug packed so firmly that percolation would involve a matter of weeks, while the percolator was left uncovered for the admission of dirt and to allow the loss of alcohol by evaporation.

Of course, these are extreme instances, and I do not, because of them, advocate buying everything. On the contrary, I advocate making everything that we can ourselves, and for my own part, I buy very few preparations. Neither do I mean to reflect too severely upon the ability of the clerks, who, in the average store, are chosen more for their ability as salesmen than for any other reason, and it is unfair to expect that they shall have all the desirable attributes in addition thereto. Moreover, the employers are not materially their superiors in these matters.

Then, too, no matter how competent we or our assistants may be, there are some things that it seems to me, we cannot afford to make ourselves, because of the time involved in their preparation. I would cite Seidlitz Powders as an example. The cost of the materials for a gross of these is something over \$1.20 while they can be bought, guaranteed U. S. P., for \$1.40.

I believe that a pharmacist's time is worth too much to spend it in weighing, mixing, dividing and folding 288 powders for a saving of less than twenty cents, even though he may have nothing better to occupy his attention than the perusal of the pharmaceutical journals. However, having bought your seidlitz powders, a very decided saving can be made by packing them yourself, a small investment in envelopes, cartons, boxes and labels, sufficing to take the place of a large stock of finished packages. Another item upon which no material saving is made, is in the filling of capsules of quinine, the difference on the two-grain size amounting to only about fifteen cents per thousand. Of course, if one has a boy who must be kept busy in order to keep him out of mischief, it may pay to do even such things as these, rather than to depend upon the manufacturer.

To sum up, there are the following arguments in favor of purchasing many preparations:—First, a saving of time, which if considered at its true value, would frequently mean a saving in cost as well; second, an assurance of a preparation skilfully prepared, and conforming to the required standard.

At this point, however, I would call attention to the necessity of specifying exactly the preparations desired and a careful inspection of the labels; for the most dependable manufacturers have their favorite formulæ for many preparations, claimed by them to be superior to their official counterparts, and these special preparations are likely to be sent unless careful specification be made. These may be, as claimed, superior to the U. S. P. and N. F. products, but where there are two or more formulas for an article bearing but one name, and when these

differ materially in their content of a potent drug, there arises the danger of over-dosage, due to the patient becoming accustomed to a weak preparation, and later being furnished with a stronger one, and not knowing of the change, continuing the same dosage. Even if no actual danger were the result of this, the different strengths of the various preparations dispensed under the same name, results in uncertainty of effects, and a consequent loss of faith by the prescriber in the efficacy of drugs, and may be a leading reason for the abandonment of their use.

In favor of making our own preparations it may be said:—first, in most instances there is a material saving in the cost; second, preparations can be made in such quantities as are justified by the demand, so that they are less likely to become deteriorated by reason of age; third, if U. S. P. and N. F. formulæ are followed, the lack of uniformity due to varying private formulæ, however good the latter may be, is obviated, and identical preparations will be dispensed everywhere; fourth, this is a part of true pharmacy, which no man who loves his profession would willingly abandon.

No doubt other reasons, both *pro* and *con*, will occur to the minds of my auditors, but I have said enough to show that there are two sides to this, as there are to most questions.

## SOME PHARMACEUTICAL NOTES.

WILLIAM R. WHITE, PH. C.

*Oleate of Mercury, U. S. P.*:—This when kept in glass ointment jars for a month or more, will discolor on the top. By covering the surface of the oleate with distilled water and adding hot paraffine until a thin layer is formed when cold, the oleate can be kept for a long time without change.

*Spirit Etheris Nitrosi*:—Practically, all of the Spirit of Nitre dispensed by pharmacists, is made by diluting one pound of the concentrated spirit with twenty-one pounds of cooled alcohol. This concentrated spirit is very volatile and boils at about 63° F., and unless manipulated very carefully some of it will be lost by evaporation. This loss can easily be avoided by cooling both alcohol and concentrated spirit, inserting a champagne tap in the cork of the nitre bottle, attaching a glass tube to it by means of a small piece rubber tubing and, after inserting the glass tube in the alcohol, opening the cock of the champagne tap and inverting the nitre bottle. If a hole is made in the stopper of the alcohol bottle and the glass tube snugly fitted into it there will be no loss. The writer believes that faulty manipulation is the cause of so many samples of Spirit of Nitre being reported below standard by the inspectors.

*Powder's Solution*.—This preparation is made by boiling arsenic trioxide and potassium bicarbonate in a concentrated aqueous solution until the arsenic is dissolved, adding the remainder of the water and the color.

The U. S. P. says that when pot. bicarb. is heated to this temperature, it is converted into the carbonate which is more alkaline than the bicarbonate and consequently it dissolves the arsenic more readily. This being true, why not use the carbonate in proper amount instead of the bicarbonate?

In making syrup without heat, if the water is added to the sugar, lumps form which are hard to break up; if the sugar is added to the water with continuous stirring, after a part of the sugar has been added, the solution becomes somewhat viscid and the last of the sugar will ball up and float and it requires a great deal of stirring to dissolve it, but it has been observed that if all of the sugar (free from lumps) is poured into the water without stirring, the greater part will be dissolved and no lumps will be found either on the top or bottom, and that the excess on the bottom can be easily dissolved by stirring a short time. Much time and labor is saved by this method, where large quantities are made.

In very hot weather, such as is often experienced in the South, it is impossible to dispense Zinc Oxide Ointment and Belladonna Ointment when made according to the U. S. P. formulæ in a solid state. The U. S. P. should permit the addition of from 5 to 10 *per cent.* of white wax in the summer time.

A sample of citric acid was purchased which formed a yellow solution when dissolved. Analysis showed a large amount of iron present.

Below are given two incompatible prescriptions with criticisms:—

R Strontium Bromide..... 4 drams  
 Mixt. Rhubarb and Soda, q. s. ad..... 3 ounces  
 Misc.

When the strontium bromide was added a strong effervescence occurred and carbon dioxide was given off freely. This was caused by a reaction between the strontium bromide and the sodium bicarbonate in the Mixture of Rhubarb and Soda which formed sodium bromide, carbon dioxide and water and precipitating strontium carbonate, according to the following equation:—

The gas was allowed to escape before bottling and a shake-label attached.

R Tr. Ferri Mur..... 1 ounce  
 Dil. Phosphoric Acid..... 1½ ounces  
 Syr. Hyphosphites (Churchills), q. s..... 1 pint

However mixed there was produced a heavy gelatinous white precipitate of Ferric Hypophosphite with perhaps some calcium phosphate. By using the Tinct. Citro-Chloride of Iron a precipitate is avoided and a yellowish transparent solution is produced.

When sifting tartaric acid or beta-naphthol, great annoyance is often experienced by the powders irritating the skin. By applying talcum powder freely to the face and hands the trouble may be avoided.

Tinct. Iodine applied to a silver nitrate stain on the skin, followed by an application of ammonia water, will change the stain from black to white and it will be removed.

Peroxide of Hydrogen, applied to a stain of ferrous iodide on the skin, will liberate the iodine, making a red stain, a mixture of dilute acetic acid and sodium hyposulphite will instantly remove this.

## DIFFICULT PRESCRIPTIONS.

J. LEON LASCOFF, PHAR. D.

## I.

R	Chloretone .....	1 gr.
	Homatropin hydrochloride.....	1 gr.
	Aq. Camphore.....	2 dr.

A precipitate was formed which dissolved on warming and later re-precipitated on cooling. We used distilled water, instead of the camphor water, and a clear solution was obtained. After exposing the first mixture in an open vessel for a time, the solution became clear, showing that the precipitation was due to excess of camphor. The liquid being already saturated with the latter cannot dissolve any other salt which is soluble only in this proportion (Chloretone is soluble—1 in 100). This can also be applied to other *saturated* solutions in which no other salt can be dissolved.

## II.

R	Sod. Bromide .....	15.0 gr.
	Antipyrin .....	2.0 gr.
	Glycerin .....	30.0 cc.
	Aqua, q. s. ad.....	120.0 cc.

This prescription has very often a green color. This is due to traces of nitrous acid present in glycerin, which reacts with the antipyrin and gives the green color. By the use of Glycerin C. P. a colorless mixture is formed.

## III.

R	Potass Citrate .....	2 dr.
	Syr. Ipecac .....	$\frac{1}{2}$ dr.
	Syr. Pruni Virginiana.....	1 oz.
	Aqua, q. s. ad.....	3 oz.

This prescription was sent to us for experiment. We find that the potassium citrate neutralizes the acetic acid, which is added in preparing the syrup of ipecac, to hold in solution the constituents of ipecac, as emetine and others. As the acid is neutralized, the constituents are precipitated. To prevent this, add to the syrup of ipecac, a few drops of acetic acid before mixing. In this case you will get a clear mixture.

## IV.

R	Calamini .....	4.0
	Zinci Oxidi .....	6.0
	Glycerini .....	30.0
	Olei Amygdalum dulcis.....	30.0
	Aq. Calcis, q. s. ad.....	120.0

If this prescription is compounded in the order it is written, the oil separates, and no amount of shaking will cause it to mix. To have this prescription properly made, mix the oil with an equal amount of lime water, and shake until an emulsion is formed. Then add a few drops of Fl. Ext. Quillaja and gradually add the remainder of the lime water and the glycerin. Mix the powders in a mortar, and rub up with the mixture. This will form a nice uniform lotion. Even after standing a few days, the powder was still in suspension.

## V.

R Deutoiodureti hydrargyri.....	0.2
Potassii iodid.....	30.0
Tincturae Iodi.....	0.4
Syrupi Ferri Iodidi.....	45.0
Aqua q. s.....	120.0

This prescription which is red on first mixing becomes decolorized on standing. The diluted hypophosphorous acid of the syrupus ferri iodidi reacts with the free iodine of the tincture, forming hydriodic acid which is colorless. To have the free iodine which is wanted present in this prescription, therefore the syrup ferrous iodide (1890) which does not contain hypophosphorous acid, should be used. This forms a clear, red mixture, which remains so on standing.

N. B.—The physician informed the patient not to accept the prescription unless it was of red color.

## VI.

R Liq. Potass Arsenitis.....	2 dr.
Syr. Ferr. Iodidi, q. s.....	2 oz.

Liq. Potass Arsenitis contains potass. carbonate. The potassium bicarbonate on boiling being converted into carbonate. This,—if the syrup does not contain diluted hypophosphorous acid, as the syrup of U. S. P. 1890,—will react with the ferrous iodide, forming a precipitate of ferrous carbonate, which is converted into ferric hydroxide. To prevent this precipitation, use a syrup containing accurate amount of diluted hypophosphorous acid, or neutralize the Fowler's Solution with diluted hypophosphorous acid before mixing, and you get a perfectly clear mixture.

## VII.

R Olei Cadini.....	20.0 cc.
Aqua. Destil, q. s. ad.....	120.0 cc.

Oleum Cadinii could not be emulsified by the ordinary emulsifying agents, neither could a suspension of the oil in water be obtained. The best way to prepare this is to emulsify the oil with the yolk of an egg, then adding a few drops of Fl. Ext. Quillaja (Soap Bark). This helps saponification.

---

 RED GUM.
 

---

 JOHN K. THUM.
 

---

*Eucalyptus rostrata*, sometimes referred to as Australian Kino, and more popularly known by the name "Red Gum," is to be found on the market, pharmaceutically, in the form of troches and in a fluid form, misleadingly termed by the manufacturers, a fluidextract.

Like Kino, U. S. P., it contains considerable tannin which makes it extremely valuable as an astringent. The so-called fluidextract has obtained some vogue among throat specialists as a local application in place of the well-known Glyceri-

tum Tannin, it being much more agreeable and pleasant to the patient, and is just as efficient as the latter preparation.

While all the manufacturers who market a fluid form of red gum have it listed in their price lists as a fluidextract, some have an asterisk placed beside the word and, on referring to the footnote, one finds these words:—"those fluids which do not represent the crude drug, minim for grain"; which is a tacit confession that it is impossible to make a hundred *per cent.* solution of this drug.

From a study of the literature relating to this drug,—and this literature, by the way, is scant,—one is informed that it is soluble in cold water to the extent of 80 to 90 *per cent.* This is wrong. It is extremely doubtful if as much as 30 *per cent.* is soluble in cold or even in boiling water. My experience leads me to believe that less than 20 *per cent.* of the drug is soluble in boiling water, and that it refuses to remain in solution without the addition of varying amounts of glycerine; without this addition gelatinization always results. My experience also showed that the use of alcohol in effecting solution is unnecessary or is at least less effective than a menstruum consisting of water and glycerin. Heat must be used. I found that after shaking twenty parts of the powdered drug with eighty parts of cold water, at intervals, for twelve hours, two parts of drug remained in solution. By heating in a flask on a water bath for fifteen minutes and frequently shaking, about 10 *per cent.* is dissolved. Unfortunately after a few days a jelly-like mass resulted. This, however, as mentioned above, can readily be overcome, or rather avoided, by the addition of glycerin, or better still, by heating on a water-bath with equal parts of glycerin and water.

After more or less experimentation, which I need not recount here, I evolved the following formula and method of procedure which seems to meet all the requirements of those physicians who wish to use Red Gum as a local application:—

Red Gum, powdered.....	200 gm.
Glycerin .....	250 cc.
Water, a sufficient quantity to make.....	1000 cc.

Mix the glycerin with five hundred cubic centimeters of water, and triturate the powdered red gum with sufficient of the mixture to produce a smooth paste. Transfer this to a flask by the aid of the remainder of the mixture of glycerin and water and heat on a water-bath for one hour; filter through purified cotton, keeping the funnel well covered. Finally, pass sufficient water through the filter to obtain one thousand cubic centimeters of fluid.

#### TURKISH SUPPLY OF GUM TRAGACANTH.

Owing to the scarcity of labor due to military levies the gathering of most of this year's yield of Asia Minor gum tragacanth was prevented. The local stock remaining from last year does not exceed 30 tons. There has been little demand this year from European buyers, but some small shipments have been made to the United States. Prices are abnormally low, but increased freight rates bring them to almost the usual level. Good natural gum sells for 38 cents per pound c. i. f. New York. The white variety is slightly dearer. *Consular Report.*

## Section on Pharmacopœias and Formularies

Papers Presented at the Sixty-Second Annual Convention

### PHARMACOPOEIAS AND FORMULARIES OF THE WORLD.

R. H. NEEDHAM.

Mr. Otto Raubenheimer offered an exhibit of Formularies, principally German ones, at the last meeting of the Section on Pharmacopœias and Formularies, in Nashville. At the same time he delivered a very interesting lecture on the different works, taking up each one in detail. The effort of Mr. Raubenheimer to acquaint the Section with the Pharmacopœias and Formularies of the Continent, led the President, I presume, to assign to me the task of compiling a list of the publications. While I welcomed the assignment and made preparations to present a more complete list, circumstances, over which I had no control, have prevented me from completing the list as I had planned.

To increase the interest in this paper I will make explanations concerning several publications.

I have not included in my list a large number of formularies and receipt books in the United States, confining my attention to the recognized authorities of other countries.

Great Britain has a long list of so-called pharmacopœias, which are in reality formularies, almost every hospital or infirmary having its own formulary. "Squire's Companion to the British Pharmacopœia" and his "Pharmacopœias of the London Hospitals," (published by J. & A. Churchill, London, edited by P. W. Squires) have been standard works of reference in London and England for over forty years. The former is the classic commentary of British Pharmacopœias, originally issued after the first British Pharmacopœia appeared, has kept pace with both medical and pharmaceutical science. The latter has been in existence over a quarter of a century, devoted not only to giving information concerning pharmaceutical processes, but has been a repository of everything worth while, regarding new remedies. "Martindale's Extra Pharmacopœia" is edited by Dr. W. H. Martindale and Dr. W. Wynne Wescott, published by H. K. Lewis, London. The latest edition appears in two volumes, the second part being devoted mainly to analysis, organotherapy, bacteriology and physiologic chemistry. The British Pharmaceutical Codex is published by the Pharmaceutical Society of Great Britain, with a view of providing formulæ for mixtures, etc., in imitation of the popular specialties issued by the drug houses and to combat the increasing tendency of giving trademark names to synthetic chemicals. The Pharmaceutical Formulas and Provincial Hospital Formulas are issued by

the publishers of the Chemist and Druggist. The Pharmaceutical Formulas devotes itself to the practical work of the drug store, almost entirely, though its information is encyclopedic in character and therefore very valuable to the practising pharmacist. Canada, in addition to the British Pharmacopœia and the Canadian Formulary, uses the United States Pharmacopœia, National Formulary and the Dispensatories.

"The Taxa" of Russia is an authorized official list of the prices that a pharmacist may charge for drugs, chemicals and pharmaceuticals in various quantities. In addition to the Russian Pharmacopœia there are a number of Formule published as an appendix to the official "Taxa." Two German Formularies, translated, are in common use.

Cuba, in addition to the Spanish Pharmacopœia, uses French works, translated. Mexico also uses several translated French texts in addition to the Dispensatory.

I desire to express my appreciation for services rendered me in compiling this list. Assistance was given by Mr. Otto Raubenheimer, Burroughs Wellcome & Co., London, the managers of Parke, Davis & Co. in London and St. Petersburg, and several others.

#### LIST OF PHARMACOPOEIAS AND FORMULARIES.

##### UNITED STATES.

United States Pharmacopœia.  
National Formulary.

##### GREAT BRITAIN.

British Pharmacopœia.  
Martindale's Extra Pharmacopœia, 1912.  
Dublin Pharmacopœia.  
British Homœopathic Pharmacopœia.  
Squire's Companion to the British Pharmacopœia.  
British Pharmaceutical Codex, 1911.  
British Dental Pharmacopœia.  
Provincial Hospitals' Pharmacopœia (Formularies):  
Bradford Infirmary.  
British Hospital for Diseases of Skin.  
Charing Cross Hospital.  
City of London Hospital for Diseases of the Chest.  
Evelina Hospital for Sick Children.  
Hospital for Consumption and Diseases of the Chest, London.  
Hospital for Diseases of the Throat, London.  
London Hospital.  
Manchester Royal Infirmary.  
Middlesex Hospital, London.  
Royal Hospital and Infirmary, Edinburgh.  
Royal Naval Hospital, Haslar.  
Saint Bartholomew's Hospital, London.  
Saint George's Hospital, London.  
Saint Thomas' Hospital, London.  
Sheffield Union.  
Pharmacopœia, Guy's Hospital, London.  
University College Hospital.  
Universal Pharmacopœia.  
Squire's Pharmacopœias of London Hospitals.

Royal College Physicians of London.  
Mericat—Chirurgical Pharmacopœia.  
Prescriber's Pharmacopœia.

##### FORMULARIES (Proper)

Pharmaceutical Formulas, 9th Edition.  
Pocket Formulary, (H. Beasley.)  
Bournemouth Formulary, (Bournemouth Pharmaceutical Association.)  
Pharmaceutical Formulary, 1904, (J. O. Braithwaite.)  
Unofficial Formulary, (British Pharmaceutical Conference.)  
Formulary, (Central London Throat, Nose and Ear Hospital.)  
Glasgow and West of Scotland Formulary, (Glasgow and West of Scotland Chemists Association.)  
Universal Formulary, (R. E. Griffith.)  
Compendium of Pharmacy and Druggists Formulary, (W. B. Kilner.)  
Tables of Materia Medica with Formulæ, (J. Kirby.)  
Practical Hints and Formulas, (B. Lillard.)  
Pharmaceutical Formulas, 1911, (Peter MacEwan.)  
Formulary for New Remedies, (E. Magendie.)  
Manual of Formulæ.  
Druggist's Handbook of Formulas, (J. H. Nelson.)  
Introduction to Pharmacy with Formulas, (E. Parrish.)  
Pharmaceutical Journal Formulary (Pharmaceutical Society of Great Britain.)  
Gray's Supplement, (E. Redwood.)

## IMPORTS OF POTASH SALTS IN FEBRUARY.

Public interest in the statistics regarding imported potash salts is keen, both by reason of their wide application in the manufacturing and other industries and the fact that the United States is still dependent upon foreign countries for practically the entire supply thereof. The following table shows the imports of potash salts during the month of February, 1915, compared with February of last year. The figures are so grouped as to show those potash salts used chiefly as fertilizers, which are entered by the long ton, and those which are used in the arts and chemical industries, of which the unit of quantity is the pound.

Articles Exported	February, 1914		February, 1915	
	<i>Quantities</i>	<i>Values</i>	<i>Quantities</i>	<i>Values</i>
Fertilizer salts:—				
Kainit ..... tons	72,008	\$321,723	1,852	\$18,445
Manure salts.....do	12,451	121,422	900	11,748
Sulphate of potash.....do	5,098	210,327	1,378	59,804
Muriate of potash.....do	13,172	131,820	22,818	836,368
Other potash salts:				
Carbonate of potash.....pounds	1,671,685	49,410	1,317,849	46,045
Caustic potash.....do	520,166	49,607	308,805	17,508
Nitrate of potash.....do	22,699	928	....	.....
Cyanide of potash.....do	5,641	890	266,654	39,327
Other potash salts.....do	638,112	52,149	156,014	12,429

## Contributed and Selected

### FURTHER FACTS ABOUT DRUG IMPORTATIONS.

HARRY B. FRENCH, PRESIDENT OF THE SMITH, KLINE AND FRENCH CO.

Under the heading of "Some Facts Concerning Drug Importations," by Dr. H. H. Rusby, of New York, in the "Journal of the American Pharmaceutical Association," of February, 1915, Dr. Rusby criticises the article contributed by Mr. J. W. England, on "Drug Importations," in the January issue of the Journal.

Dr. Rusby states that he agrees with Mr. England's general conclusions and claims as there outlined. He adds,—“On the other hand, there are statements in Mr. England's article that have no basis whatever in fact, and there are others which can be justly weighed only in the light of existing conditions to which he makes no reference.” Dr. Rusby picks out this statement made by Mr. England,—“It is manifest that such a system gives a large scope for the use of personal influence and offers the possibility of gratifying private grudges. It is not asserted or intimated that any of the officials of the ports of this country are guilty of such nefarious practice, but it is certain that the system encourages such practice.” Dr. Rusby answers by saying—“It is very likely that at some ports where little business is done, and where very few persons are employed, such knowledge incidentally reaches the analyst, but this is not a design in the establishment of the methods.”

Any one who is acquainted with the importations at different ports knows that this is no answer at all. It is true that, in the Port of New York, where the bulk of importations is made, the system may be so enforced that Dr. Rusby is not acquainted with the ownership of the goods, the samples of which he is examining, and in fact we know that this is the case, as Dr. Rusby has made a statement to that effect, and he has the confidence of every man, but this condition does not and cannot prevail at other ports, where the importations are exceedingly small as compared with the importations at the Port of New York. If the office of Dr. Rusby was filled by a dishonest official, there is no doubt that he could obtain any information that he might wish to obtain as to what lots were represented by the samples submitted to him for examination. The statement of Mr. England remains with undiminished force. Mr. England did not directly or indirectly state or infer that any of the present officials were dishonest. He stated, and this statement is based on facts and on experience, that the tendency of the system was to debauch public officials. We may add here that this is the tendency of all bureaucratic administrations, when such officials set themselves above the law and outside of the law, and claim that they are justified in taking extra legal or illegal action, if in their opinion such action is for the benefit of the public. This course has been repeatedly followed, and for the reason stated, by

officials of the United States Government in their actions taken under the Federal Food and Drugs Act.

Dr. Rusby criticises, also, Mr. England's statement that Government officials higher up are apt to support the findings of their subordinates. This statement on the part of Mr. England can be established by facts. It can be shown that importations were rejected by officials of the United States Government for reasons that were extra-legal or illegal, and that their action was supported on appeal to the authorities at Washington, although it was known at Washington that the grounds on which the lower officials refused admission were illegal. Dr. Rusby explains Mr. England's position by a remark that is not worthy of that high repute in which he is held by the community. We hold that the following remark is not an argument and is an unjustifiable attack upon those who are trying to remedy a defect in the law and a great wrong, that is now inflicted upon the American people.

Dr. Rusby states, that in his opinion, the reason for Mr. England's impressions is that, "An importer who has always insisted upon his approval of the objects and purposes of the drug law and who has given it his continued support, suddenly finds himself saddled with a shipment of the unfitness of which neither he nor any one else has any doubt." This expression of Dr. Rusby needs only to be stated to receive the condemnation that it deserves. He possibly may have the writer in mind, when he has made this statement. It is hardly necessary for the writer to define his position or the position of the house of which he is President, but he can call upon the Department itself to prove that he has gone so far as to re-export goods that have been released by the Department, which he was told were released through a mistake.

Dr. Rusby adds,—“The rarest thing in all my experience, although I have known it to occur, is for an importer to exhibit a willingness to have the law justly enforced when this would result in a loss to him.” It is unfortunate that Dr. Rusby's opinion of business integrity is so exceedingly low, but from our personal experience, we can give him certain facts that show a willingness on the part of importers to take a loss rather than to accept the delivery of goods that are of inferior quality.

Quoting further from Dr. Rusby, he states,—“A far more serious question than any of the above is that of providing for judicial review of the findings of experts, which Mr. England strongly approves, and in which approval he is supported by many of the ablest lawyers, judges and legislators in the country. On general principles, it would seem clear that the importer should have this right and it is only the result of experience that can lead one to take the opposite view.”

It is worth while to quote Dr. Rusby at some length on this argument as the appeal to Congress to revise the law and give importers the right to appeal to the courts, is the chief argument of the agitation that is now spreading throughout the country. We would ask your attentive consideration to the argument presented by Dr. Rusby against granting such a right to importers, and in considering his argument it must be borne in mind, that this is a right already conceded to all importers of merchandise into the United States excepting only importers under the Federal Food and Drugs Act. Importers under the Federal Food and Drugs Act only claim the same right of appeal to the court of appraisers and to

the United States Court of Appeals, that is now granted to other importers, and now for Dr. Rusby—

"All seizures of interstate shipments are subject to court review and many hundreds of such cases have been brought since the Federal Food and Drugs Act went into operation. At many of these trials, I have been a listener and I can recall scarcely any into which gross perjury did not enter. Were one to judge only by his observations of such a case, he would be likely to conclude that there is no other class of persons so dishonest as these expert witnesses. Leaving out of consideration all cases in which there is a fair ground of error and all differences of opinion, I do not hesitate to assert that in nearly all important cases one or more witnesses testify to what they know or fully believe at the time to be untrue. Our unfavorable opinion of these results must be qualified by the reflection that in most such cases, some experts have been asked to testify who have refused to do so, on conscientious grounds. Nevertheless, it is never difficult for an attorney to find one or more who are willing to thus degrade the profession. I have seen a chemist deny the pinkish-color which promptly appeared in the test performed in the court room while he was looking on. I have known a witness, after having sworn to an entirely different result from that which he had previously obtained, to retire under instructions of his attorney, so that he would not see the result of the same test applied in the presence of a jury and in this way would escape being compelled to state the truth concerning it. I have heard a witness testify that all volatile oils contain alcohol in varying amounts, oil of peppermint about 90%. In this case, because that witness occupied the chair of *Materia Medica* in a medical college, while the one opposed to him was in a college of pharmacy, it was only with great difficulty that the jury could be convinced that his testimony was incorrect. It is this ignorance of the jurors, their complete dependence upon the statements submitted, and their unfitness for grasping and interpreting technical facts, in which the danger of this method of deciding such questions principally resides. As to the tendency of the witness to speak correctly, we must consider whether government witnesses, with no other influencing motive than that of justly and impartially upholding the law, are more or less likely to testify truthfully than are men who have been offered a rich fee, often a temptingly large one, to say that for the saying of which they are to be paid."

You will note from a careful perusal of this argument that Dr. Rusby does not advance any argument whatever against the justification of this request on the part of importers, and indeed, he goes so far as to say that this appeal is supported by many of the ablest lawyers, judges and legislators in the country, excepting that his personal experience is that experts as a class are thoroughly dishonest and that being so, it would be wrong to give the right of appeal to American citizens, and that it is very much better to leave these questions to be settled as they now are; that is, in the hands of public officials who have autocratic power, who customarily act beyond the law and contrary to the law, because of their interests in the welfare of the people, and who are presumably honest and incorruptible.

It should not require more than a statement of this argument to show that Dr. Rusby has placed himself out of court and that his arguments are not worthy of serious men who still have some faith in humanity and believe that, on the whole, men are honest. It is unfortunate that in Dr. Rusby's argument he has failed to appreciate the basic principle that underlies the demand for the right of an appeal to the courts. If the right was granted, such appeals would not be made on a question of quality, excepting the importer had a sure case, for the reason that no merchant is going to expose himself to the public as an importer of inferior goods. The appeal will be made only when necessary to protect the importer against the extra-legal and illegal acts so constantly perpetrated at the present time by officials of the Government of the United States and for the purpose of correcting inequalities of administration at the different ports.

In the Declaration of Independence is stated that it is the right of every man to pursue "life, liberty and happiness." This statement is no longer true as ap-

plied to a very large section of the American people. It is within the power to-day of a combination of officials of the Government of the United States to drive a man out of business and so make it impossible to enjoy that right which our Declaration of Independence declares to be inalienable. It is probable that the law is unconstitutional, because it deprives the American citizen of this birthright, but this cannot be known until a case is carried to the Supreme Court. Congress has always been looked upon as the bulwark of the personal freedom of American citizens. In passing the Federal Food and Drugs Act without the right of judicial appeal, Congress, probably unintentionally, betrayed the most important interests of the people.

Bureaucratic government is the government of despotism. It is practiced to its fullest extent in Russia and there has a political as well as a civil application. There is no difference in the Federal Food and Drugs Act as now enforced in this country and the bureaucratic government of Russia, under which a citizen can be seized in the dead of night and disappear forever, excepting that this particular law applies only to civil matters. If, however, the American people tamely permit bureaucratic government such as this in a civil matter, the time will come when it will be extended to political matters. The power of a large section of the American people for the "Pursuit of Life, Liberty and Happiness" has been placed in the hands of the United States Government officials, more or less honest, and more or less able. There should be no hesitation in redressing this wrong. Those of your readers whose ancestors helped to make this country what it is, know well that it was their intention to build up a free government under the law. It was because of bureaucratic government that this country severed its relations with Great Britain. While the abuses now existing in the administration of the law justify this amendment, this argument is of secondary importance, and the basis on which those numerous organizations that have taken up this matter with so much interest make their demand, is government of the people under the law.

To the Editor:—

I thank you for permitting me to see proof of Mr. French's reply to my last article in the Journal. My views were correctly stated in that article, and they were based upon knowledge rather than opinion.

I will thank you to say that I disclaim the intent to refer to any particular house or houses, which would be an abuse of my position. My language, as quoted by Mr. French, "It is the rarest thing in my experience," etc., makes my statement quite general. I think the most difficult feature in the administration of the law, as to both foods and drugs, has been this very common endeavor to secure the admission of shipments, after their unfit character has been demonstrated. Indeed, this by no means tells the whole story. The possibility of succeeding in such attempts, under the peculiar provisions of the law, has largely frustrated its beneficent purposes, and it will eventually become necessary to devise some new legislation to prevent this procedure.

I would like to add that what Mr. French says about the general tendency of bureaucratic administration is fully justified. It is hardly too much to say that

this growing tendency is alarming. We differ as to its bearing on the administration of the Food and Drugs Act. I am quite as sure that an ordinary jury is not the proper body to decide such technical questions as the identity, purity and quality of drugs, as Mr. French is to the contrary. Decision by a properly qualified body is no more bureaucratic than by an unqualified one, as the common jury certainly is.

Very truly yours, H. H. RUSBY.

---

### THE PRICE OF SUCCESS.\*

---

W. H. COUSINS, WICHITA FALLS, TEXAS.

---

Every desirable achievement has its price. Every step forward costs effort. The chap who said, "There is no excellence without great labor," was not an amateur in the game of life. The man who said, "Eternal vigilance is the price of success," had cut the cards in the great game until he knew whereof he spoke, for verily no man was ever born with this much wisdom. Such philosophy comes only from those who have had the tutorship of necessity, that grim teacher who is dean of the school of experience in which not only fools but even the wise must learn the hard lessons of life. In fact, we are mostly fools until we go through the hardships that are thickly strewn along the road to success. Success is not a stationary attainment; it is forever moving away from its pursuers, and its luring call of work, work, work, comes with every waking moment and in dreams. The amassing of a million dollars may not mean success. The million that means success is the earned million that came little at a time through unceasing vigilance and hard work, and not the million that came accidentally when fate was loafing on the job. Eternal vigilance and hard work will put the poorest business on this continent into pay dirt as a profit-maker. Eternal vigilance is head work. There are many better pitching arms in the big leagues than the twirling wing of Christy Mathewson, but greater heads there are none. Success in business is a big game that works head and hands to full capacity. Hands cannot win without head work. Head will never score working alone. Brilliant ideas are born only to die in an unsystematized business that needs arranging from the curb to the alley. The store that looks like first money in a clean-up contest will never get anywhere if the want book and the advertising are overlooked. Every business that is approaching success must have at least one man whose judgment is supreme. He is a kind of a court of last resort. He has observed, worked and toiled. No detail has escaped his eagle eye or his lightning powers of discernment. He has seen things happen and things that have happened once do not have to happen again to remind him of the effect that comes from a certain cause. Once in a great factory on whose pay roll were thousands of men, with many experts and each supposed to possess all the information that went with his job and to be able to cope with any situation that might arise, it happened that the belt on a big machine was slipping and the operator of the machine did everything he knew to do, to no avail. The master mechanic of the plant was called and exhausted his collection of tricks

---

\* The Practical Druggist, March, 1915.

of the trade, including the pouring of sticky belt dressing on the belt to make it hold the pulleys, but it continued to slip. After all had given up in despair, they went to the private office of the "Old Man" who had established the factory more than thirty years ago. The problem that had baffled the expert was laid before him and he solved it in two minutes; in three words he said, "Tighten the belt." It matters not how small the business nor how large, there must be "an old man" (or a young one) who knows things and holds himself personally responsible for everything that happens and never makes an excuse when things go wrong or takes credit when they go right. No business ever succeeded where nobody carried responsibility. How many successful business men could you find in the whole world who would buy a business, employ enough clerks to operate it, and go away and leave it expecting to succeed? Success depends mainly on the man. Some men would arrive at success in spite of all the obstacles that can be piled into their paths. The man who succeeds must pay the price. He must play the game for blood. He must not muff the grounders, beef at the umpire or play to the grand stand. Any time he takes his gun eye off of the works a long fly will slip out of his mit and old "Compet" across the street puts one by for a home run. In "eternal vigilance" eternal means what it says. Not semi-weekly or every now and then, but every minute. The chap who thinks he has bought success and the goods are not delivered, did not pay for it. The money was not on the mahogany. He mistook eternal for occasionally: He loafed at the plate until the umpire called two and swiped at the third one, and missed it seven feet. I call to mind a hot-house confection who smokes, swears and wears men's clothes, who thought he had a half-Nelson on success. He blew up recently, and when the smoke had cleared away it was found that he owed various firms scattered along from Augusta to Galveston a matter of twenty-eight thousand dollars for drug-store merchandise that a burglar would move back into the store if he found them on the curb. This lad was not allowed to succeed. He was sandbagged by environment. He has a good heart inside of him, and if his heritage had been poverty, success would have been his. The old birds of the pill game would have held him up as a shining example of the man who whipsawed fate and won in spite of hardships and a muddy track if he had only been born poor. His old man was too strong with the bank parchment when Willie was being rubbed into condition for his life's work in a college of pharmacy. He propagated and grew an idea that the big thing in the knowledge works was to put a large-size crimp in father's standing at the First National. He buckled down and boned in school sometimes when he was not too busy passing out the coin and got away with the pure white lambskin with the gold freckle down in the corner. Father got a bill for the damage, the figures of which looked like the number on a Rock Island coal car. The invoice was for clothes, books and laboratory apparatus, with enough incidentals to pay for the college campus at the rate of a hundred bucks the front foot. Father merely groaned and asked for exchange on New York. The bank clerk thought he had bought an ocean liner or a railroad. When Willie fell off the three-forty-five limited, father was there to take a look at his Golden Calf. The old gentleman looked at him with one of those long, searching glances that he was always wont to bestow on a likely-looking piece of real estate that in a few years would grow a crop of installment-plan bungalows that would pay

seven hundred *per cent.* profit. Now Father had sat in where it took gold eagles by the shovel-full to stay and had threes beaten to a whisper. He had put thirty to one on a pony that died on the track with slow fever. He was an inexperienced man at coming loose from coin in hunks. But as he gazed on Son he classified him as the most expensive luxury he had ever tried to maintain. As he thought of him and looked at him his Daddy Nature softened and his affections got mushy. He said to himself: "Ain't he my boy? Ain't he a son of his little mother? Didn't he bring home the bacon? Ain't he got a sheepskin from the college and a clearance from the State Board? Will I let him go out and fight fate for success like I did? Not on your petrified likeness. By the eternal heck, I never piked and I won't commence it now. I'll buy him a drug store with gold fixtures and a private office." The latter decision was the bomb that sent Willie's chances of success Hadesward. Father bought the store and Willie bought everything that was for sale by the entire drug trade. It was the old story, with the sheriff in the last act. It took Willie just two years to erase his John Henry from Bradstreet's book of batting averages and give the creditors the sand bag square on the bean. Willie did not intend to do it, but he could have steered an ocean liner across the Atlantic just as easily as he could pilot the big store with the big expense account toward success. In paying for success money is not a legal tender. Grilling experience, bloody perspiration and sleepless nights are some of the things exacted of the man who would burn his John Henry into the exclusive scroll.

Really successful pharmacists in most cases began with a sink full of unclean vials in the tender years of childhood, and by putting every moment that can be spared from sleep to the task of getting information on the game, finally in the afternoon of life are able to retire from the tile and spatula and spend the gloaming finding out what has happened in the world during their exile. They know the great Remington, but never heard Tolstoi. They are familiar with Wilhelm Bodemann, but not wise to Elbert Hubbard. The sweet-faced bride of former years, now a gray-haired matron, on a Sunday morning in spring leads him into a church where a kindly faced minister extolls the joys of the great beyond and the beauty of the golden city; and in the daze he is catching himself wondering what rent the best corners will bring, and if the cigarette tax is the same in heaven as in San Antonio.

Alfred Henry Lewis told the whole story when he made his "Old Cattleman" say: "Success in life hain't in holdin' a good hand, but playin' a poor one well." I have seen more wrecks that were attributable to bad buying than to any other one cause. Many a little drug store that would be a miniature mint if the proprietor could be satisfied with his own profit instead of trying to get the jobber's profit also by buying more goods than he needs to save a small discount. A small retailer is beginning to get in the game when he learns to buy a gross of Sal Hepatica for eight dollars instead of paying ninety for it.

This wonderful feat is accomplished by buying each dozen with the same eight dollars with which he bought the first dozen. A jobber's 2% each month beats a manufacturer's five, once a year. Of course, there are several thousand other things to do in the retail drug business besides the buying. Any man in the business is entitled to pull a bonehead occasionally, but must not pull the same one

twice. There is no primrose path that leads to success. Primrose paths lead elsewhere; especially is this true of the retail pill game. Success never fluctuates in the market. Fate is a square dealer and sells it to all of us at the same price. Sometimes it leaves us with flighty heads and nervous hands, but when we win there is a sweet satisfaction in knowing that we beat the game. Every man in the game has more brain than he uses, more ability than he shows, and is capable of more effort than he spends. Every successful man must study his business if he is to know it. He may know it to-day, but he must keep his eye on the signals or won't know it to-morrow. Every bit of power, both mental and physical, that the human dynamo will generate and apply is THE PRICE OF SUCCESS.

---

## STATE NARCOTIC LEGISLATION.

(EDITORIAL COMMUNICATION.)

THE enactment of the Harrison Act marks an epoch in the history of narcotic legislation. It furnishes a new and original method of controlling the manufacture, sale and use of narcotic drugs, through the U. S. Treasury Department. It is both a police and revenue measure. It is intrastate as well as interstate in scope, covering both the states and the nation, and to a degree, if not altogether, it eliminates the necessity for state narcotic laws.

The Harrison Act, with its system of registration and recording, is an experiment in narcotic legislation, and the results will be studied with deep interest, both at home and abroad.

Each state has its sovereignty. The Harrison Act cannot abridge or interfere with the operation of the laws of any state respecting the manufacture, sale and use of narcotic drugs unless such laws are in direct conflict with the Federal statutes.

There is a general tendency on the part of the states to amend existing narcotic laws, or enact new ones, along the lines of the Harrison Act, and this attitude raises a very important question:—

Is it desirable *at this time* for the states to legislate, or is it not more desirable, in view of the experimental nature of the Harrison Act, and the possibility that Congress may amend it at the next session, to await the results of the experiment, and then amend or delete?

At the March meeting of the Philadelphia Branch, A. Ph. A., a resolution was offered by Dr. F. E. Stewart, seconded by Professor J. P. Remington, and carried unanimously: "That the Philadelphia Branch of the American Pharmaceutical Association hereby suggests to the Senate and House of Representatives of Pennsylvania that further legislation regarding the possession, sale, distribution and dispensing of habit-forming drugs be held in abeyance until a proper trial shall be given to the recently enacted Harrison Act intended for the control of the same, and that, therefore, further action regarding the bills now before the Senate and House relating to this subject be postponed in accordance with this resolution."

---

• Senate Bills Nos. 177, 185 and 198.

The following letter, addressed to the members of the Senate and House of Representatives of Pennsylvania, has been issued by the Philadelphia Drug Exchange:—

"A number of bills\* have been introduced in the Legislature of the State of Pennsylvania modeled after the Harrison Act (H. R. No. 6282) for the regulation of the purchase, sale and possession of opium, coca leaves, their salt, derivatives or preparations, recently enacted by Congress and made effective as of March 1, 1915.

The Philadelphia Drug Exchange is in hearty accord with the purposes of the Harrison Act, but wishes to enter its most earnest protest against the enactment of State legislation along the same line, because it is absolutely unnecessary.

The Harrison Act is the result of years of study by experts of the Federal Government and representatives of Medicine and Pharmacy from all parts of the country, who carefully studied state and local conditions and framed a law that met the requirements of all sections.

From our technical knowledge of the conditions under which drugs are sold, we believe that the Harrison Act will prove to be the most effective law yet devised for minimizing the "dope evil" and that it should be given a fair and reasonable trial to demonstrate its possibilities and limitations before legislation of a similar character is enacted by the State.

Under the Harrison Act, dealers must keep a record of their purchases and sales of the interdicted drugs. Now, if each of the 48 states passes a law similar to the Harrison Act, dealers doing a national business will have to keep 49 sets of records, probably with widely varying requirements. Such a task would be most burdensome and with no compensating advantages to the public.

We trust you may see your way clear to oppose all narcotic legislation at this session of the Legislature."

At present, the existing state narcotic laws do not provide for the registration and recording of the manufacture, sale and use of narcotic drugs, and this omission makes them far less efficient than the Harrison Act.

It is claimed that the Federal law really does not go beyond the means of furnishing evidence to detect violation of the state laws, and that a state board of pharmacy securing evidence for prosecution under a state narcotic act would have access to the records required by the Harrison Act; but, the Commissioner of Internal Revenue has decided "that the board could get (and then only upon the payment of a fee) nothing in the way of a record except a verified copy of the statement of *purchases*, which revenue collectors may require; no records of any sales by wholesalers or manufacturers could be obtained in any manner unless it would be by the impracticable, almost impossible, procedure of getting the revenue collectors of districts to supply verified copies of a record of the purchases of every person registered in their districts—and this would not account for sales to persons outside the state. And when it had these records—if they could have been obtained—what could the board of pharmacy do? Nothing but report any discovered illegality under the Harrison Act to the Federal authorities!"—(N. A. R. D. Journal, 1915, 1159.)

If state narcotic laws are amended or enacted, and do not require the keeping of records, but depend upon the records of the Internal Revenue Department as evidence for prosecution, then the state will face the practical difficulties above mentioned, or if the state requires the keeping of records, also, then the work of the Harrison Act will be duplicated many times, and dealers doing a national business, or even business in a number of states, will have to keep numerous records and make numerous reports to the state authorities, and the result will be confusion worse confounded.

If the state narcotic laws are in conflict with the Federal Act, it should be determined whether such differences are important or unimportant, and then, of

course, if the differences are serious, the state laws should be made to conform with the Federal statute and with each other, *but*,

"Is it really necessary *at this time* to enact state legislation similar to the Harrison Act, in order to ensure proper and sufficient protection of the public?" Would it not be better for the states to wait until the Harrison Act has been tried-out? The Harrison Act is a good law, the best that has yet been devised, but its possibilities and limitations have not been determined, and its administration will doubtless reveal some defects. Why not wait, and then, in the light of experience with the Act, amend or enact state laws, if necessary, especially adapted to state conditions and in co-ordination with the Federal Act?

The arm of the Federal Government is longer than that of any state or municipality and much more efficient. It reaches into the remotest sections of the country, and experience may show that the Federal Act will serve the public—both general and pharmaceutical—much better than 48 state laws; and, that one law will be far less burdensome to pharmaceutical interests than 49 laws, goes without saying.

J. W. ENGLAND.

## PROFESSIONAL PHARMACY FROM THE VIEWPOINT OF THE COMMERCIAL LABORATORY.\*

---

F. E. STEWART, PH. G., M. D.

---

By commercial laboratories I mean the laboratories of the great commercial houses engaged in the pharmacal and pharmaco-chemical industries. What are these laboratories doing for the medical and pharmaceutical professions? They are making most of the chemical, pharmacal and biological preparations used by physicians in treating the sick.

Why are the commercial laboratories making these preparations? Why are not the retail druggists making them? These closely related and mutually dependent questions cannot be answered in five minutes or in an hour.

As a general proposition it may be stated that the concentration of capital and the centralization of business has brought about this change.

No well-informed person will dispute that, from an economic standpoint, the business of manufacturing and dealing in medicinal drugs, chemicals and preparations of the same, can be carried on more successfully on a large scale, than when operated in a small way. This applies to all lines of manufacture and the drug business is no exception. The great department store is an outcome of this economic fact. The great manufacturing plants in all lines, exist because of it. The so-called trusts exemplify the same principle. The retail druggists, as a dealer in ready-made goods, is in competition with the department stores. As stated by the widow of an old-time prominent druggist in Philadelphia, "When I was a girl, no one thought of going anywhere but to a drug store for a sponge or tooth-brush, but now nobody thinks of going to a drug store for either. Everybody goes to the department store for both." While this statement is somewhat exaggerated, it illustrates the tendency of the times.

---

\* Read at the February Meeting of the Philadelphia Branch A. Ph. A.

All will agree that true pharmacy is developing along the lines of higher education and greater technical skill. The standardization of medicinal drugs, chemicals and galenical preparations required by the Pharmacopœia is for the most part impractical except when conducted on a large scale, thus raising the practice of pharmacy, in this respect, above the reach of those retail druggists who are not doing sufficient business to make standardization work practicable.

The retail druggist, as a manufacturer of chemicals, is in competition with the great chemical houses with their laboratories and skilled chemists. What chance has he in such competition? Is there any reason why he should not purchase his supplies from the chemical manufacturing houses?

The retail druggist, as a manufacturer of galenicals, is in competition with the great commercial laboratories of the pharmaceutical manufacturing houses. While his chances in competition may be somewhat better than in competing with the chemical houses, the very fact that galenical manufacturing has been drifting away from the retail drug store into the great commercial laboratories, is a strong argument against the claim that the retailers can manufacture just as economically as the large laboratories. If he can purchase his supplies of galenical preparations from the manufacturing pharmaceutical houses at greater advantage than to manufacture them himself, is there any good reason why he should be denied the privilege? If he can prepare his chemicals and galenicals with greater economy in his own laboratory than to purchase them, he certainly does not display business ability if he does not do so.

There are of course two classes of pharmacists and manufacturing houses. One class regards pharmacy simply as a commercial business of barter and sale and the other class regards it as a profession. The former considers it perfectly legitimate to manufacture and sell almost anything for which there is demand or for which a demand may be created by advertising. The latter hold themselves responsible as professional men and experts in drugs and realize that the commercial methods of the former are incompatible with scientific and professional requirements. Professional experts cannot afford to employ misleading methods of advertising or give countenance to pretense and error in conducting their business. The moment the public has occasion to doubt the sincerity of their statements, their reputation as experts is gone, and they sink to the level of the charlatan and quack. Pharmacists in purchasing their supplies from manufacturing houses should not forget this distinction between professional pharmacy and pharmaceutical quackery, and should discriminate in favor of manufacturers who refrain from using such illegitimate commercial methods in their business or supply quacks with the products of their laboratories for carrying on the business of quackery.

The retail druggist, as a manufacturer of nostrums, is in competition with the commercial laboratories of the great manufacturing houses engaged in the nostrum business, but the nostrum business is not pharmacy. The nostrum business is the quack medicine business, whether carried on by a so-called patent medicine house or by the great manufacturing houses engaged in the pharmacal and pharmacochemical industries. True pharmaceutical practice consists in the selection, preparation, preservation, compounding and dispensing of medicines, prepared in accordance with common standards jointly adopted by the medical and pharmaceut-

ical professions and conforming with scientific and professional usages in their manufacture and sale. This is the true ideal of pharmaceutical practice. The false ideal is every pharmacist a manufacturer of his own nostrums and a prescriber of the same by recommending them over the counter as specifics or cures. The retail druggist who manufactures and recommends his own nostrums or the nostrums of manufacturing houses thereby becomes a quack doctor. He prescribes without a diagnosis and thereby violates the first essential to correct prescribing.

Before the advent of the advertising business, the retail druggist as a nostrum manufacturer was an individual quack doctor. The advent of the advertising business changed all this and to a large extent the retail druggist became an agent for the sale of nostrums manufactured by great nostrum manufacturing houses. The great manufacturing houses engaged in the nostrum business in advertising nostrums to the public are prescribing at long range without a diagnosis. The principle is the same whether the prescribing is done at long range without a diagnosis or at short range without a diagnosis.

Individualism in the practice of pharmacy is taught by every college of pharmacy and to the extent that such individualism is practicable, the ideal is correct, but individualism in the practice of quackery by pharmacists is not pharmacy. Such practice means pharmaceutical degradation.

Much of the so-called new remedy business carried on by the great manufacturing houses advertising to the medical profession is but another phase of the nostrum business. One class of nostrums is advertised in the newspapers to fool the people and the other class is advertised in the medical journals to fool the doctors. During the past thirty years tens of thousands of alleged new remedies have been introduced to the medical profession as wonderful discoveries in therapeutics. Not one-tenth of one *per cent.* of them have proved of any special therapeutic merit in comparison with older and better-known drugs used for the same purpose.

Now, it must be perfectly apparent that the retail druggists as manufacturers of nostrums and quack medicines cannot successfully compete with the great manufacturing houses engaged in this business.

It has been said that the retail druggist is threatened with extinction and this is not surprising under the circumstances. The question for us is:—What are you going to do about it? Many remedies have been suggested, one of which is the coöperative manufacturing of nostrums by commercial laboratories conducted under the control of retail druggists' organizations. But this plan is similar to that of the fish who jumped out of the frying pan into the fire to save himself from being served up for breakfast.

The pharmacists of New York recently had an opportunity to do something about it that would have placed pharmacy in the city of New York on a professional basis and gained public confidence. What did they do about it? Did they coöperate with Commissioner Goldwater in his attempt to force the nostrum manufacturers to publish their formulas so the public might be no longer deluded? No. They missed their opportunity and joined with the nostrum manufacturers in a protest against this. How can pharmacy expect to be ranked as a

professional vocation when the pharmacists as a body align themselves with those who prey upon the gullible public and exploit the sick.

I am saying nothing against the supplying of the public with pharmaceutical preparations made in accordance with scientific and professional requirements and dispensed to meet the demands of the public for legitimate household medication. That is one of the functions of the pharmaceutical profession. I am saying nothing against chemical and pharmacal manufacturing houses who introduce new and valuable therapeutic agents to the medical profession.

While we have all been debating what to do about it, the public has been waking up to the situation and the results are before us in drastic legislation which has been enacted and is being proposed for the protection of the public against fraud in the drug business. Why was it necessary to pass the Pure Food and Drugs Act? Why was it necessary to pass the Shirley amendment for the prevention of lying in advertising? Why was it necessary to pass the Harrison Bill to prevent the public from being debauched by habit-forming drugs? Were these bills aimed at the practice of true pharmacy, namely, the business of manufacturing and dispensing medicines, prepared in accordance with common standards jointly adopted by the medical and pharmaceutical professions, and dispensed to meet the demands of legitimate pharmaceutical and therapeutic practice? Were they not rather aimed at illegitimate practices on the part of physicians, druggists and the manufacturing houses?

Now, what is the remedy? Is not the remedy to be found in coöperation between the medical and pharmaceutical professions and the great manufacturing houses with their commercial laboratories having as its object the legitimate practice of pharmacy and medicine? Such coöperation means the elevation of pharmaceutical practice to the position of a learned profession, ranking as a peer with the other learned professions. It means the raising of the pharmacist to a higher position socially. The great commercial laboratories under such a system of coöperation would no longer be used for illegitimate purposes. They would be no longer employed for the manufacture of nostrums and quack medicines. They would be employed in the production of medicinal drugs, chemicals and preparations of the same, prepared in accordance with the latest scientific and professional requirements. The proper enforcement of pure food and drug laws, including amendments intended for the abolition of lying in advertisements, will bring this about. The educated and trained pharmacist will then be protected from unfair competition with quacks and pretenders. To the extent that each individual pharmacist is provided with capital and facilities to do his own manufacturing, he will purchase his supplies from the great commercial laboratories. If not properly provided with capital and laboratory facilities, he will be protected in so doing. To the extent that he cannot do his own manufacturing, he will maintain his individual responsibility as a professional man because he will be in position to guarantee that the medicines he dispenses in prescriptions and over the counter are made in accordance with common standards, jointly adopted by the medical and pharmaceutical professions.

It does not mean that new therapeutic agents will not be discovered and introduced commercially, but it does mean that this work will be done in coöperation

with the medical profession through the channels of original *materia medica* research. The work will be coöperative. In the coöperation the universities with their laboratories, hospitals and clinics will take part, and also the commercial laboratories of the great manufacturing houses engaged in the pharmacal and pharmaco-chemical industries. Thus the commercial laboratories instead of being a menace to professional pharmacal and medical practice will become of great service to the medical and pharmaceutical professions, to the science of medicine and to the cause of humanity.

---

THE HOUSE OF DELEGATES OF THE A. PH. A.  
IN REGARD TO ITS BETTERMENT.

---

PROF. HENRY P. HYNSON.

---

The forty and more well organized and active state pharmaceutical associations which are most satisfactorily and efficiently protecting and promoting general pharmaceutic interests in the several states of which each is a part, are a positive pride and especially gratifying to all loyal and ambitious pharmacists.

All these state associations, you may be reminded, have exactly the same comprehensive character of membership. They include all the different phases of pharmacy and the basis of organization and the objects to be obtained are practically the same in all of them. So far as their diversified membership and the work they are doing is concerned, they are also in exact accord with the American Pharmaceutical Association of which they are proudly accepted children.

These state associations are in no way justly subject to adverse criticism, yet, they, like many other good things, should progress naturally, and their usefulness and helpfulness should be steadily extended. Indeed, notwithstanding all that has been accomplished by them, these organizations may be made of still more value to their local constituents and of immensely more assistance, nationally. How?

By giving them equal uniform and exclusive representation in a national body composed of their delegates. This may be done by giving them sole control of the House of Delegates of the A. Ph. A. Why?

Because, owing to the character of their membership, which is catholic, pharmaceutically, and not restricted to any special branch of pharmacy, the A. Ph. A. is the only national body with which they can consistently be connected, and the only one with the objects and work of which they can perfectly harmonize. In fact, they are now practically state divisions of the American Pharmaceutical Association; certainly, they are more possibly so and more nearly so than are any other class of local associations.

What advantages would follow correlating these state associations and more closely attaching them to the A. P. A.? Any one giving a moment's open thought to the subject will see. The assistance and interest of other state associations may be secured to further progressive measures originating in any one of them, if the measure is not strictly local. The accomplishments and the helpful experiences of one may be passed on to the many. The voice of each local association

may be heard by the others on national issues and the greatly desired uniformity of state laws and state measures may be more quickly secured, for instance, state pure food and drug acts, mercury bichloride regulations, poison labeling, weight and measure laws. There will always be interesting and helpful suggestions coming from the local bodies, regarding subjects that have been intelligently discussed "at home."

Representation in a national body will greatly stimulate and encourage these state associations, by giving them an outlet for their views and conclusions regarding national questions. It will give them vastly increased opportunities for action, such opportunities as they are seeking and must have.

To the A. Ph. A., the advantages of this more formal and more orderly connection will be manifold and far-reaching; the establishment of such a House of Delegates will at last make the American Pharmaceutical Association truly the national representative of pan-pharmacy, geographically and otherwise, and pan-pharmacy needs such representation just now to enable it to present a dignified, worthy and effective front when coöperating with other comprehensive representative bodies, such as the American Medical Association, the American Public Health Association or the American Chemical Society. Such a house of delegates will undoubtedly increase interest in the parent body and must, of necessity, bring greater loyalty for the A. Ph. A. in all state associations that have become an integral part of it through the House of Delegates. This greater interest will surely add individual members to the A. Ph. A., especially if such membership is made a pre-requisite to the office of delegate. It would be a happy sequel, indeed, if, finally, all members of the state associations should feel, in duty bound, to become members of the mother body, whose House of Delegates is composed solely of their delegates. It is safe to predict that these state associations *will* sooner or later get together just as the state boards have already become correlated. Why should it not be now and with the A. Ph. A.? This would be good for them and for it.

Now, then, what are the difficulties in the way? None, the getting rid of which would not greatly benefit and more consistently place all those involved. The disposal of the delegations that have been taking part in the transactions of the House of Delegates is absolutely all that is in the way of making it a creditably consistent, unusually useful, deservably desirable body.

Ninety-nine organizations appointed delegates and forwarded their credentials to the A. Ph. A. last year. Of these, six were purely local associations of retail druggists, which may have or should find national representation, like other such organizations in the National Association of Retail Druggists. Eleven sending credentials were local branches of the A. Ph. A., which already have full representation in the Council. Two were women's organizations, one of these an auxiliary of a national association, the other a local body; both could find agreeable placement in the Women's Section. Thirty were schools of pharmacy for which splendid national representation is offered in the American Conference of Pharmaceutical Faculties. Three were college alumni associations, which could more properly secure national representation through their respective schools or through the state association of the commonwealth in which their organization is

located. One, only, was a medical school, which is effectively represented, nationally, by the American Association of Medical Schools.

Delegates, representing the Executive Departments of the U. S. Government, the Republic of Cuba and the American Medical Association should, without question, be accorded much more respectful recognition at the General Sessions and should not be placed on an equal footing with the delegates from very small local associations, college alumni associations, local branches, *et cetera*.

There now remain but the six national pharmaceutic bodies, each specifically representative of some particular phase of pharmaceutical pursuit; these were N. W. D. A., N. A. R. D., N. A. B. P., A. A. P. C., A. M. M. P., N. A. D. C., and the thirty-six uniform state associations.

It is contended that the *National Associations* representing, nationally, the different phases or divisions of pharmacy should be given recognition at the general sessions, or should be formed into a congress to themselves, where they may equally discuss such matters as are of general interest to such national bodies as a whole.

Attempt has been made, and it is hoped that the attempt has been successful, to show that the already organized fully equipped state associations, which represent localities and not phases, so many as thirty-six of which appointed delegates last year, are the only bodies of the many, which can orderly and equally take part in such a house of delegates, also to show that such a body of delegates would be most helpful to the state associations and equally as helpful to the American Pharmaceutical Association and to American pharmacy as a geographical whole. What is your verdict?

Changes in the By-Laws. The only necessary change required in the By-Laws of the House of Delegates of the A. Ph. A., to accomplish that which is herein suggested, will be a change of Article 1, Chapter 11, which reads as follows:—

"Article 1.—Representation. The membership of the House of Delegates shall consist of three regularly-elected or appointed delegates from the Local Branches of the American Pharmaceutical Association, State and Local Societies, Colleges and Schools of Pharmacy and delegates from the National Association of Retail Druggists, National Wholesale Druggists' Association, American Medical Association, National Association of Boards of Pharmacy, Women's Organization of the National Association of Retail Druggists, National Association of Manufacturers of Medicinal Products, American Chemical Society, Association of National and State Food and Dairy Departments, Association of Official Agricultural Chemists, and from the departments of the Army, Navy and Public Health and Marine Hospital Service, the American Association of Drug Clerks, the credentials of whom shall be approved by the Council; together with the member of the Council, appointed by the chairman of the Council. The President, President-elect, Treasurer, General Secretary and the Chairman and Secretary of the Council shall be members *ex officio*."

With the greatest possible respect for the incongruous mass of organizations named in the Article, it is thought no harm or discourtesy will be done to any of them and much greater respect will be shown for a number of them, by changing the Article to read:—

"Article 1.—Representation. The membership of the House of Delegates shall

consist of three regularly-elected or appointed delegates from the several state pharmaceutical associations and from associations of a similar character regularly organized in the several territorial and insular possessions of the United States, provided such delegates are members of the American Pharmaceutical Association at the time their credentials are signed."

It will, probably, be desirable to have it understood and stated in the By-Laws that any action of the House of Delegates will be an expression of the sense of the assembled delegates of the state associations, also that the House of Delegates may appoint committees to execute its orders, but that no action of the House of Delegates will be binding upon the A. Ph. A., unless endorsed by the Council.

Messrs. F. H. Freericks, Joseph L. Lemberger, W. C. Anderson and F. M. Apple, members of the Committee appointed, with myself, at Detroit, "to investigate the House of Delegates and see if its usefulness could not be improved," are especially requested to make comment upon the subject in hand and communicate these comments to the other members of the Committee, including the chairman. Members of the House of Delegates and officers and members of the American Pharmaceutical Association are requested to make comments and communicate them to the chairman and other members of the Committee, either directly or through the Pharmaceutical Press. The editors of the Pharmaceutical Press are urgently requested to study the subject and take part in this discussion.

## THE PERCENTAGE OF MOISTURE LOST IN THE PREPARATION OF SOME OFFICIAL AND UNOFFICIAL DRUGS.\*

EDWIN L. NEWCOMB, P. D.

The following compilation of data, concerning the moisture lost in the drying of vegetable drugs, has been prepared from the record of student work in Pharmacognosy at the University of Minnesota. The drugs were collected during the first few weeks of each college year (September and October). Where washing was necessary to remove adhering soil, care was taken to remove all wash water before weighing the fresh drug. All drugs were dried at a temperature of about 80° C., except where otherwise stated. The drying was continued where artificial heat was employed, until all but two to four *per cent.* of the water was removed. A battery of five iron double-walled, gas-heated ovens were utilized for this purpose (v. 84, pp. 201-214, American Journal of Pharmacy). "Room temperature," as used in this paper, means from 68° to 70° F. This temperature was maintained by automatic thermostat controls.

	<i>Percentage of Moisture</i>
<i>Belladonna Folia</i> :—	
(a) 1913 Crop, leaves and tops not over 7 mm. dia., with flowers and numerous berries. (Average <i>percentage</i> of moisture lost in 30 samples).....	71.00
(b) 1914 Crop, leaves only.....	82.00
<i>Belladonna Radix</i> :—	
(a) 1913 Crop. (Average of 29 samples).....	75.00
(b) 1914 Crop. (Average of 2 samples).....	73.6

\* Presented to the Scientific Section, Minn. State Pharm. Assoc., St. Paul, Feb. 10, 1915.

*Stramonium, (Datura Stramonium):—*

- (a) 1913 Crop, leaves and flowering tops with stems not over 7 mm. in dia. .... 65.3  
 (b) 1911 Crop, leaves alone. .... 83.00  
     (a) Average of 24 samples.  
     (b) Average of 30 samples.

*Datura Tatula, (Stramonium, U. S. P. IX):—*

- (a) 1913 Crop, leaves and flowering tops with stems not over 7 mm. in dia.  
     (Average of 19 samples)..... 65.7  
 (b) 1914 Crop, leaves only. (Average of 48 samples)..... 82.7

*Datura fastuosa flava:—*

- 1911 Crop, leaves only. (Average of 7 samples)..... 81.00

*Datura fastuosa alba:—*

- 1911 Crop, leaves only. (Average of 27 samples)..... 81.2

*Digitalis purpurea:—*

Leaves of first year's growth. Cleaned from adhering soil and dried quickly  
 at 80 to 100 degrees Cent.

- (a) 1913 Crop. (Average of 95 samples)..... 80.9  
 (b) 1913 Crop. (Average of 62 samples)..... 81.6  
 (c) 1914 Crop. (Average of 28 samples)..... 80.3  
 (d) 1914 Crop. (Average of 51 samples)..... 81.71

*Digitalis grandiflora:—*

Leaves of the first year's growth, prepared the same as *D. purpurea*  
 (Average of 21 samples, 1913 crop)..... 79.4

*Digitalis lutea:—*

Leaves of the first year's growth, prepared the same as *D. purpurea*

- (a) 1913 Crop. (Average of 21 samples)..... 80.5  
 (b) 1911 Crop. (Average of 4 samples)..... 81.06

*Digitalis lanata:—*

Leaves of the first year's growth, prepared the same as *D. purpurea*.

1913 Crop. (Average of 7 samples)..... 81.1

*Digitalis ferruginea*

Leaves of the first year's growth, prepared the same as *D. purpurea*. 1913

Crop. (Average of 11 samples)..... 78.6

*Salvia sclarea:*

Leaves of the first year's growth, cleaned from adhering soil and dried at

room temperature. (Average of 15 samples.) 1913 Crop. .... 81.4

*Verbascum phlomoides:*

Leaves of the first year's growth, prepared like *Digitalis*. (Average of 29

samples.) 1913 Crop. .... 81.8

Percentage of  
Moisture

*Althaea officinalis*:—

Leaves of the first year's growth, cleaned and dried at room temperature.  
(Average of 22 samples.) 1913 Crop..... 66.8

*Symphytum officinale* and *S. asperrium*:—

Leaves of the first year's growth, prepared the same as *D. purpurea*.  
(Average of 22 samples.) 1913 Crop..... 81.4

*Mentha Piperita*:—

- (a) Leaves and tops not over 10 cm. in length, cleaned and dried at room temperature. 1913 Crop, average of 51 samples..... 73.5  
(Humidity was high during the drying.)
- (b) 1914 Crop, dried same as above, average of 51 samples..... 80.00  
(Humidity was low during the drying.)

*Salvia*:—

- (a) Leaves and tops not over 10 cm. in length, cleaned and dried at room temperature. 1913 Crop, average of 49 samples..... 70.4
- (b) Leaves only, cleaned and dried at room temperature. 1914 Crop, average of 9 samples ..... 73.2

*Marrubium*:—

- (a) Leaves and tops not over 10 cm. in length, cleaned and dried at room temperature. 1913 Crop, average of 20 samples..... 67.6
- (b) Leaves only, 1914 crop, dried as above, average of 9 samples..... 74.00

*Humulus*:—

- (a) Strobiles dried at room temperature, 1913 crop, average of 17 samples.... 71.7
- (b) Strobiles dried at room temperature, 1914 crop, average of 25 samples.... 76.8

*Cannabis sativa*:—

- (a) Pistillate tops dried at room temperature, sample contained many seed, average of 27 samples..... 69.2
- (b) 1914 Crop, prepared as above, also containing some seed, average of 24 samples ..... 69.7
- (c) Pistillate tops collected from wild growing plants, with very few seeds present. Average of 6 samples..... 70.7

*Ruta*:—

- (a) Leaves and tops not over 10 cm. in length, 1913 crop, dried at room temperature, average of 14 samples..... 72.7
- (b) Leaves only, 1914 crop, dried at room temperature, average of 6 samples.... 76.1

*Valeriana*:—

- (a) The carefully cleaned rhizome with about 10 cm. of the roots, dried at room temperature, 1913 crop, average of 46 samples..... 73.3
- (b) 1914 Crop, prepared as above, average of 41 samples..... 74.4
- (c) 1913 Crop, prepared as above, average of 29 samples..... 75.00

*Levisticum*:—

- (a) The roots and crown carefully cleaned by washing, and dried at room temperature, 1913 crop, average of 32 samples (2-year-old plants)..... 75.7
- (b) Prepared same as above, 1914 crop, average of 5 samples (3-year-old plants) ..... 64.00

*Inula*:—

The roots carefully cleaned by washing, and dried at room temperature.  
1913 Crop, 2-year-old plants, average of 32 samples..... 66.6

*Taraxacum*:—

The roots carefully cleaned by washing, and dried at room temperature.  
1913 Crop, 2-year-old plants, average of 32 samples..... 73.4

*Althaea*:—

The roots carefully cleaned by washing, and dried at room temperature, not peeled. 1913 Crop, 2-year-old plants, average of 27 samples..... 65.6

*Phytolacca:—*

The roots carefully cleaned by washing, and dried at about 80° Cent. One-year-old plants, average of 18 samples..... 74.9

*Apocynum:—*

The roots and rhizomes carefully cleaned by washing, and dried at room temperature. Average of 6 samples..... 60.00

## A CRITICISM OF THE UNITED STATES PHARMACOPEIAL DESCRIPTIONS OF VEGETABLE DRUGS.

---

A THESIS SUBMITTED TO THE FACULTY OF PURDUE UNIVERSITY.

---

CHALMERS JOSEPH ZUFALL.

---

### INTRODUCTION.

The inspection of crude drugs in a pharmaceutical manufactory requires continual reference to the descriptions of official drugs in the United States Pharmacopœia. While these descriptions are considered authentic, the question often arises, are they really accurate and correct for commercial drugs? Comments and criticisms are repeatedly found in the pharmaceutical journals which lead one to suspect inaccuracy on the part of the pharmacopœia committee which wrote these, and the purpose of this investigation is to determine how well these descriptions can be applied to the drugs of commerce and to authentic specimens.

The drugs are to be taken, one at a time, and large quantities of the material studied. The conditions for this study at the Eli Lilly and Company's plant are almost ideal, for we are able to see more than a mere sample from each bag; we can see the entire contents of the bags and bales as they are emptied in the mill-room ready for grinding. Then the pharmacopœial description is compared with as many authentic specimens as possible. The herbarium specimen is first checked up with the botanic authorities and then the crude drug, the herbarium specimen and the pharmacopœial description are compared. In many cases, three to five mounted specimens of the one species from widely-separated regions were used, thus giving any variations due to climatic conditions.

*Aconite*—The six lots and ten samples examined show that the pharmacopœial description is correct for *Aconitum napellus* except as to the thickness of the root. Many roots were found to be 35 mm. in diameter at the crown. The pharmacopœia gives this diameter as "10 to 20 mm." It should be given as "10 to 35 mm. in diameter at the crown."

In order to aid in distinguishing the official drug from *A. fischerii*, which is being offered on the market as the true aconite, the pharmacopœia should add that the "starch grains are 4 to 12 microns in diameter." Those of *A. fischerii* are much larger, being 10 to 22 microns.

*Apocynum*.—The pharmacopœial description of *Apocynum* is "The dried rhizome of *Apocynum Cannabinum*, *Linne*, or of closely allied species of *Apocynum*."

The phrase "or of closely allied species of *Apocynum*" should be omitted, for this includes *A. androsaemifolium*, a "closely allied" species, so closely resembling *A. cannabinum* that it is difficult to distinguish between the two species, even when the plants are in flower. Yet, *A. androsaemifolium* has different medicinal properties and is used under the name of "Bitter Root." The foremost pharmaceutical botanists admit that they do not know the difference, and Henry Kraemer of the Philadelphia College of Pharmacy states that the only difference between these two roots is the presence of stone cells in the cortex of *A. androsaemifolium* and not in *A. cannabinum*. We have collected several specimens of the different species of *Apocynum* and are trying to establish the differences between these two species.

PLATE I.

SAVIN ADULTERANT—TRANSVERSE SECTION OF LEAF.

E, Epidermis; H, Hypodermis; R, Resin duct; S, Sclerotic cells.

*Belladonna Leaves*.—*Belladonna* leaves are often adulterated with the leaves and fruit of *Scopola carniolica*. The leaves of this adulterant resemble those of *Belladonna* so closely that it is almost impossible to detect it unless the fruit is present. So it seems wise to replace the phrase "frequently with the flowering tops intermixed," with the following, "usually with the tops possessing the dark, brown or black, globular, indehiscent fruit, showing above the reflexed calyx

lobes." This will exclude the tops of *Scopola* which usually possess the yellow or light brown, subglobular, transversely dehiscient fruit which is almost completely enclosed by the thin, paper-like calyx.

The requirement of 0.3% alkaloids is too low for *Belladonna* leaves. In 61 assays of samples and lots made in the last five years only three have been as low as 0.3%. The average of these 61 assays is 0.44%. This indicates that the pharmacopœial requirement is too low for prime drug and should be raised to at least 0.4%.

*Berberis*.—During the examination of six lots, many *Berberis* roots were found to be 40 mm. in diameter so that the size should be changed from "3 to 20 mm." to "3 to 40 mm."

A peculiarity of *Berberis* not seen in other roots is that it splits upon drying. It would be well to state this in the pharmacopœia as one of the characteristics of *Berberis*.

*Buchu*.—It is impracticable to obtain *Buchu* without some stems. Some of these stems are thick, woody and undoubtedly inert while "others are thin and contain the active constituent in considerable amount." (1)

The *per cent.* and character of these stems should be controlled by the pharmacopœia.

The stems in five lots and of seven good samples offered for sale average .8%. The pharmacopœia should exclude *Buchu* containing more than 10% stems. The stems permitted should not be more than 1 mm. in diameter.

*Capsicum*.—During the last year, it was found difficult to obtain the real *Capsicum fastigiatum*. The Japanese pepper was offered continually for *Capsicum*. The small Japanese variety answers the pharmacopœial description, but they are of a lower quality and are less pungent. The description should include the following and thereby exclude all but the genuine *Capsicum*. "The cells of the pericarp are usually quadrilateral, 20 to 55 microns in diameter, more or less wavy in outline, walls indistinctly beaded and, which is most noticeable, arranged in distinct longitudinal rows." (2)

*Cardamom*.—While the pharmacopœia describes the cardamom "fruit" as official, it adds that "the seeds alone contain active and valuable constituents."

The seeds alone should be made official, since they alone are of value, and thereby lessen the amount of inert material in the preparations.

These inert pods may vary considerably, for some pods may be full while others may contain only a few seeds or may be empty. These empty pods, being much lighter than the seeds, will accumulate at the tops of the bag on being handled. Thus the druggist may get a large *per cent.* of pods in his first preparations made from a bag, while there may be very few in the last preparations; thus his products will vary considerably.

Since the seeds or "decorticated cardamoms" are plentiful on the market, there seems no reason why they should not be made official instead of the "fruit."

*Coca*. The requirement of "0.5% ether-soluble alkaloids" is too low.

The average of 21 assays of lots and samples is .85% ether-soluble alkaloids, the lowest assaying .66%.

From these results it seems that the requirement should be raised to at least .75% ether-soluble alkaloids, for, if *Coca* leaves are properly gathered, properly

shipped and properly stored, they will give a much higher assay than the pharmacopœia requires.

*Colchicum Seed*:—The pharmacopœia requires only 0.45% Colchicine which would include rather poor seed. The average of 18 assays is .66% colchicine, the lowest being .53%.

These results indicate that first-class *Colchicum* seed will assay at least 0.6% colchicine, and the pharmacopœial requirement should be raised to this *per cent*.

*Cubeb*:—Cubeb berries grow in spikes, and in gathering the drug the whole spike is picked, which includes the peduncle. In drying and handling the drug, the berries become detached from the peduncles, which then occur as "stems."

PLATE II.

JUNIPERUS SABINA—TRANSVERSE SECTION OF LEAF.

E, Epidermis; H, Hypodermis; R, Resin duct; M, Mesophyll.

Some berries on the market have no stems at all, while others have an excess of them. This indicates that the stems are removed from a part of the drug, for which a higher price is obtained, and these stems mixed with other lots and the average price obtained for it.

If stems are not deliberately added to Cubebs they will make a rather constant *per cent*. of the drug, so the pharmacopœia should specify that there shall not be more than 10 *per cent*. stems, and these should not be more than two mm. in diameter.

*Ergot*:—The examination of six lots, consisting of 154 bags, indicates that a few changes should be made regarding the color of the fracture and the pharmacopœia made to read as follows: "fracture short, gray, pinkish, blue or purple," instead of "pinkish, or reddish-white."

The thickness should be "from 3 to 5 mm." instead of "about 3 mm."

*Grindelia*:—The pharmacopœia states, "The dried leaves and flowering tops of *Grindelia robusta* and *G. squarrosa*," but does not state how much of the "tops." Since the activity of this drug evidently resides in the resinous exudation and since the resin is not found in the larger stems, the length of the "flowering tops" should be given so as to exclude the larger, inert stems. The maximum length should be 30 cm.

From the description in the pharmacopœia, one would infer that the two species, *G. robusta* and *G. squarrosa*, were very much alike, whereas the leaves and scales of the involucre are distinct in the two species. The pharmacopœia describes the leaves as "about 5 cm. or less long," whereas leaves 7 cm. long were found. "Lanceolate" should not be used in describing the leaves because that includes the leaves of *G. lanceolata*, while the leaves of the two official species do not approach the lanceolate shape. Instead of "pale green" the leaves vary from pale green to greenish yellow.

The leaves are further described as "somewhat coriaceous, brittle." The leaves of *Grindelia* become very brittle upon drying and are not coriaceous.

From these discrepancies it seems best that the two species should be described separately because very often lots of drug arrive which are made up entirely of one species.

It seems that the following descriptions would be more scientific and workable than the one given in the pharmacopœia:—

*Grindelia robusta*:—Leaves 7 cm. or less long, broadly spatulate or obovate, sessile, more or less clasping at the base, finely to coarsely serrate, obtuse, light green to greenish-yellow, finely dotted, brittle; heads resinous-viscid, many-flowered, depressed-urceolate, 1 cm. broad, composed of numerous imbricated, linear-lanceolate spreading bracts; ray-flowers yellow, ligulate, pistillate sometimes absent, disk-flowers yellow, tubular, perfect; pappus of two or three mostly unequal awns about the length of the disk-flowers; taste pungent and bitter, odor aromatic and balsamic.

*Grindelia squarrosa*:—Similar to *G. robusta* except the leaves which are 4½ cm. or less in length and 8 to 15 mm. wide, usually decidedly oblong or oblong spatulate, obtuse, more or less clasping at the base, sharply spinulose-dentate, sometimes lacinate. The bracts of the involucre strongly squarrose.

*Lupulin*:—The results of examining five lots and 16 samples indicate that prime Lupulin has an amber-yellow color which should be given instead of "brownish-yellow." The latter color is seen only in drug which is not fresh.

There have been suggestions that the maximum ash limit is too low, but from our experience we know that it is not. Careless handling or willful adulteration are the only causes for the presence of the foreign mineral substance which causes the high ash in some Lupulin.

*Savin*:—The pharmacopœial description of *Sabina* is not specific enough to exclude several other species of *Juniperus*. Consequently, these other species are

found on the market offered for savin. The oils of these species are inactive and undoubtedly this is the cause of savin falling into disuse.

It is difficult to identify a species of the *Juniperus* from a twig alone, without specimens of the fruit and without knowledge of the form and habit of growth of the plant. The difficulty is twofold. In the first place, two plants which undoubtedly belong to one species, develop, if grown under varying conditions of soil and climate, very marked differences, both in general habit and in the character and mode of arrangement of the leaves. *Juniperus sabina* when found in the natural state, has decussate, ovate-lanceolate leaves, while the cultivated plant bears leaves which are more needle-like and sometimes in whorls of threes.

PLATE III.

*JUNIPERUS OCCIDENTALIS*—TRANSVERSE SECTION OF TWIG AND TWO LEAVES.

E. Epidermis; H, Hypodermis; R, Resin duct; S, Sclerotic cells.

In the second place, plants of different species have adopted a similar habit; for instance, forms of *J. sabina*, *J. phoenicea*, *J. thurifera*, *J. barbadensis*, *J. virginiana*, L. and *J. scopulorum*, Sarg. possess closely imbricated, acute or acuminate leaves, tightly appressed to the stems, and are externally almost indistinguishable one from another.

So variable are some of these plants that, of *J. Sabina*, seven varieties are recognized by Biessner and described by him in his "Handbuch der Nadelholzkunde."

In 1902, there was published by the Ecole Supérieure de Pharmacie, Paris, a

thesis by H. Henri Mongin, entitled "Etude Anatomique de la feuille des Juniperinees." He pointed out that, in the drug of commerce, besides *J. sabina*, there were to be met with *J. thurifera*, L., and its variety *gallica*, and *J. phoenicea*, L. Most people would find it practically impossible to distinguish non-fruited twigs of these species from the typical form of *J. sabina*. All have small leaves, closely appressed to the stem, giving the branches a cylindrical appearance. With fruiting specimens available, *J. phoenicea* is readily separated, having larger yellowish fruits, while the fruits of *J. sabina* and *J. thurifera* are small and bluish, resembling those of *J. communis*.

In 1874, M. E. Collin pointed out that the leafy twigs of *J. phoenicea* substituted for those of savin in French commerce. In 1902, M. Mongin found that they were still so employed in France, and indeed constituted the greater part of the drug met with in that country. He also points out that the oil of *J. phoenicea* is inactive, being similar to that of *J. communis*.

Mongin's work renders it possible to distinguish between *J. sabina* and these substitutes, even when only the young branchlets, usually met with in the commercial drug, are available for examination. *J. sabina* and *J. thurifera* and its varieties have the leaves in pairs, each pair being at right angles to the succeeding pair, i. e., they are decussate. In *J. phoenicea*, on the other hand, the leaves are not decussate, but are arranged more or less spirally with five leaves inserted almost at the same level.

Mongin further shows that large sclerotic or stone cells are found in the mesophyll of the leaf of *J. phoenicea* and less abundantly in *J. thurifera*, whilst they are completely absent in *J. sabina*. Another point of difference is the continuance of the hypodermal layer over the resin duct in the leaf of *J. phoenicea*, while in *J. sabina* the resin duct abuts directly on to the epidermis.

In 1905, Freeman stated that there occurred in commerce in Great Britain a form of savin "with more convex, less acute leaves, which are so closely appressed to the stem as to give a cylindrical appearance to the branchlets, very different it is true from the typical savin, but so closely resembling some of the forms of *J. sabina* that in the absence of fruit it is impossible to separate them by a microscopic examination." (3).

From these references we may conclude that savin has been adulterated for at least 40 years.

For some time there have been large quantities of so-called savin on the market which consists of twigs resembling somewhat the twigs of *J. sabina*, but the leaves are more convex, less acute and have an oval gland. By careful inspection it is noted that the arrangement of the leaves is not the same on all twigs. The drug is a mixture of about one-half twigs whose leaves are in whorls of threes and one-half twigs having decussate leaves. Branching twigs showed a peculiarity in that the branch had decussate leaves while the leaves of the twig were in whorls of threes. The latter fact indicates that the pharmacopœia is at fault, for these branchlets answer its requirements while the main twig of the same species does not.

In microscopic sections of this substitute, both the decussate leaves and those in whorls of threes, show the following characteristics as brought out in plate 1:

large sclerotic or stone cells in the mesophyll beside the resin ducts and the hypodermal layer extending between the resin duct and the epidermis.

A pressed herbarium specimen of *J. Sabina* showed the leaves all decussate, apex decidedly acute, longer, less convex and the gland linear-oblong. Microscopic sections show the absence of sclerotic or stone cells and the resin duct abuts directly on to the epidermis as shown in plate II. These characteristics indicate that, according to M. Mongin, the pressed specimen is properly named and that this substitute is not obtained from *J. sabina*. The leaves of the commercial drug are not arranged spirally, hence it is not obtained from *J. phoenicea* and the

PLATE IV.

CRAMP BARK—COMMERCIAL DRUG—TRANSVERSE SECTION OF BARK.

B, Bark; L, Bast; K, Corky layer.

leaves are not all decussate, hence it is not *J. thurifera*. But pressed specimens of *J. occidentalis*, Hook, have short, oval, convex leaves with stone cells beside the resin duct and the resin duct separated from the epidermis by the hypodermis. This form shows the peculiarity of having the leaves in whorls of threes on the large branches, but the branchlets from these have decussate leaves. This indicates that the substitute which has been offered for savin is undoubtedly from *J. occidentalis*.

Three specimens of *J. sabina* obtained from the New York Botanic Garden show the following characteristics in contrast with those of this substitute; leaves

spreading, acuminate, all decussate no stone cells in the mesophyll and the resin duct abutting directly on to the epidermis."

In order to exclude all but *J. sabina* the pharmacopoeial description should read as follows:—

Thin quadrangular branches bearing green, decussate leaves which are scale-like, ovate-lanceolate, acute or acuminate, appressed or spreading, imbricated; having on the back a shallow groove containing a linear-oblong gland; odor strong, penetrating, terebinthinate; taste disagreeable, resinous and bitter. In cross-section the leaves should show no stone cells and the resin duct abutting directly on to the epidermis."

PLATE V

OLEOPHYLLUM. TRANSVERSE SECTION OF BARK AND WOOD.

B, Bark; L, Bast; K, Corky layer; W, Wood.

The fact that the pharmacopoeia states that the leaves are dark green and have an oblong or roundish gland indicates that the description may have been made from commercial drug and not from known specimens of *J. sabina*.

*Scoparius.* A more definite description would be obtained if, "Thin, flexible branched twigs, 2 to 3 mm. thick, externally dark green" were replaced by "Flexible, round light green branches with five low, narrow ridges, 2 to 3 mm. thick; the smallest branches being uniformly 1 to 15 mm. thick, dark green, with five distinct wings."

*Viburnum Opulus*.—The pharmacopœia states, "The dried bark of *Viburnum opulus* Linne," and then describes the bark of *Acer spicatum*. Consequently the Cramp Bark on the market for the last twenty years has been the bark of *Acer spicatum* and, although it answers the pharmacopœial description, it is not the bark desired.

In 1912, Nathan S. Slatter, of Bennington, Vt., discovered that the Cramp Bark on the market was not the same as the bark of *Viburnum opulus*, but was that of *Acer spicatum*. He exposed the fact to Oliver A. Farwell, of Detroit, who confirmed Slatter's statement by comparing Cramp Bark of commerce with authentic specimens of *Viburnum opulus* and *Acer spicatum*.

PLATE VI.

VIBURNUM OPULUS—TRANSVERSE SECTION OF BARK AND WOOD.

B, Bark; W, Wood; C, Calcium oxalate crystals; K, Corky layer.

2. Winton "Microscopy of Vegetable Foods," pp. 523 and 524.
3. "A Comparison of The Savin Leaves of Commerce," by Wm. G. Freeman in The Pharmaceutical Journal for Dec. 16, 1905, p. 829.
4. "Confusion Over Cramp Bark," by Oliver A. Farwell. The Bulletin of Pharmacy, Vol. 27, p. 65.  
 "Manual of the Trees of North America," by Charles Sprague Sargent.  
 "New Manual of Rocky Mountain Botany," Coulter and Nelson.  
 "Illustrated Flora of the Northern States and Canada," Britton and Brown.  
 "Flora of The Southeastern United States," John K. Small.  
 "Pflanzenfamilien," Engler and Prantl.  
 British Pharmaceutical Codex.

Farwell found that in 1895, a pharmacopœial committee of revision which tried to show the difference between *Viburnum opulus* and *Viburnum prunifolium*, used *Acer spicatum* for an authentic specimen of *Viburnum opulus*. This specimen was obtained from a large pharmaceutical manufactory and indicates that *A. spicatum* was used at that time for Cramp Bark. (+)

The sixth revision of the pharmacopœia under *Viburnum opulus* gives characteristics undoubtedly those of *Acer spicatum*. Such characteristics as "fracture tough, the tissues separating in layers," are surely not those of *V. opulus*, for the bark of the latter is very brittle and gives a sharp, clean fracture.

The findings of these two men led F. A. Miller to investigate the situation. He

obtained specimens of both *Acer spicatum* and *Viburnum opulus* from Arnold Arboretum, Missouri Botanic Garden, Baltimore Nursery, Kew Botanic Garden, and the German Botanic Garden. Sections and drawings of these were made and of commercial Cramp Bark. See plates 4 and 5. These drawings show clearly that commercial Cramp Bark is taken from *Acer spicatum*, for both show the bands of bast fibres and the absence of calcium oxalate.

The accompanying illustrations are representative of all the drawings made and show the desired points.

The pharmacopœia should replace the present description by the following:—"In transversely curved pieces or quills, of variable length, and one mm. or less thick; outer surface gray, longitudinally furrowed, small oval lenticels; inner surface brownish yellow, very smooth; fracture short and clean; transverse sections show an abundance of calcium oxalate crystals in rosettes, no bast fibres; taste at first bitter and then astringent."

*Viburnum Prunifolium*.—Two characteristics of this drug should be added which will aid considerably in its identification. These are the sour odor and the peculiar, short, smooth stripe on the inner surface of the bark.

*Laboratories of Eli Lilly & Company, June, 1914.*

## REVIEW OF CURRENT PHARMACEUTICAL LITERATURE.\*

PROF. JULIUS W. STURMER.

### PHARMACEUTICAL ERA. (January.)

*Stable Bichloride Solution*.—Mercuric Chloride in aqueous solution containing also Sod. Silicate Sol. does not precipitate with ammonia. As the resulting ammoniacal sol. does not attack steel instruments, it may be found serviceable by the surgeon.

NOTE.—The author does not give bactericidal power of this solution as compared with ordinary Bichloride Sol. (J. W. S.)

Saccharin (and in particular its sodium salt) is converted into a bitter compound by action of fruit acids. The change takes place slowly at ordinary temperatures, more rapidly on application of heat.

### CHEMICAL ABSTRACTS. (Jan. 20.)

*Temperature of slaking lime*.—1. At temperatures of about 270-300° wood is partially carbonized, and in the presence of oxygen, i.e., air, it ignites. A sample of lime from marble was found to attain a temperature of 390° during slaking, and the experiment proved that the slaking lime could ignite wood.

### PHARMACEUTICAL JOURNAL. (Jan. 2.)

*Ammoniated Mercury, constitution of*.—The reaction with Hydrofluoric acid:— $2\text{NH}_3 + \text{HgCl}_2 + 4\text{HFl} = \text{HgCl}_2 + \text{HgFl}_2 + 2\text{NH}_4\text{Fl}$  points to the formula  $\text{HgClNH}_2$ . That is, Mercuric Chloride with one Chlorine atom replaced by  $\text{NH}_2$ .

### JOURNAL OF INDUSTRIAL AND ENG. CHEMISTRY. (February.)

*Hard Wood Distillation Industry in America*.—Interesting nine-page article by Edward H. French and James R. Withrow.

\* Read before Philadelphia Branch, February meeting.

## MERCK'S REPORT. (January.)

*Viscose Sponges*:—The viscose which forms a dough with Sod. Hydroxide is kneaded with hemp fibre, and Sod. Sulphate Crystals are imbedded; then oval cakes are formed and immersed in Dilute Sulphuric Acid, which hardens the viscose. Finally, the Sod. Sulphate Crystals are dissolved by means of water, thus leaving cavities, which give to the mass a sponge-like appearance.

## BRITISH PHARMACEUTICAL JOURNAL. (Jan. 16.)

*Magnesia Carbonate, absorptive power of*:—The experiment reported consisted in placing pieces of camphor wrapped in three layers of paper upon a cube of Mag. Carbonate also wrapped in paper. After two months the Mag. Carbonate had only a feeble odor of camphor, but on triturating the Carbonate with water a stronger odor developed, and on dissolving the Mag. Carbonate by the addition of citric acid, the odor developed was equal in strength to that of Spirit of Camphor. Accordingly, it is reasoned that Mag. Carbonate, like Charcoal, must be kept in air-tight containers lest it become contaminated with volatile drugs.

## AMERICAN DRUGGIST. (January.)

*Peroxide Creams*:—The article points out that animal and vegetable fats cause decomposition of peroxides, and that these fats are therefore inadmissible in peroxide cold creams. Petrolatum, starch paste, tragacanth paste, and also glycerin are recommended by the author as being unobjectionable, and suitable bases for such creams.

*Liquid Petrolatum*:—(February. Reprinted from the Report of the Council on Pharmacy and Chemistry of the A. M. A.) The article deals with the limpid oils used for atomizer sprays, and with the more viscid oils, obtained principally from Russian sources and used in intestinal stasis.

## DRUGGIST'S CIRCULAR. (February.)

*Spurious drugs*:—An article well worth reading by John Uri Lloyd.

## THE WOMEN'S SECTION AND WOMEN PHARMACISTS.

ZADA M. COOPER.

The first clause of the second article of the Constitution of the Women's Section reads like this: "The object of this Section shall be to emphasize the right and capability of women to engage in pharmaceutical pursuits as a means of livelihood." Other objects follow, all of them laudable, but this one statement is the basis for what I want to say. Under the circumstances, I suppose I cannot be altogether altruistic, but one very practical way suggests itself to me, one that I believe would benefit not only women pharmacists, but be of great value to women generally. I am also firm in the opinion that it would mean increased business to pharmacists, a fact that should enlist the interest of the women of this section who are not themselves pharmacists. But for its length, a better title for this paper would be, "How to convince druggists, now employing only men, of the need of women pharmacists, also."

To come at once to the point, the Women's Section might formulate resolutions expressing women's preference for drug stores where they can do business with women pharmacists; stating also their belief in the advantage to business; and requesting pharmacists to consider seriously the employment of women. If the resolutions should be approved by the Association they would eventually reach all

the members through the Journal of the Association. Perhaps the expense of sending copies by mail might be justified. Some other journals might publish them also, so that practically all druggists would be reached. At least, all that are worth reaching, all that we dare to hope to influence could be reached in this way. The druggist who takes no drug journal is unworthy of the title. He must be a mercenary individual or depraved and beyond reach of reform.

It would take generations to accomplish singly what the organization could do in a few years. Even if each woman were to say to the pharmacists of her community that she would like to deal with women pharmacists, it would have little effect. Men would think it only an individual whim, but if the Women's Section as a part of a great national organization so expressed itself, it would be taken more seriously and would have much greater weight. Men have known the powers exerted by organized effort for many years, but it is in comparatively recent times that women have learned the importance of coöperation. Club work is probably responsible for their getting outside themselves and overlooking minor differences sufficiently to make team-work possible. Evolution has taken us beyond the sociological stage where we "worked alone in tragic seriousness, unrelieved by a sense of humor." It has led us out into a broader usefulness where we are willing to coöperate with others. This is only one of the opportunities opening to members of the Women's Section for united constructive effort.

Without doubt there are some men who are honestly opposed to women pharmacists. They may perhaps admit a woman's abstract right to enter the profession if she so wills; they may even admit her value in *some* stores, but personally will have nothing to do with her. Even if all the women in America were to express themselves as preferring to do business in a pharmacy where there was a woman, still they would employ only men, either because they want only men's business or else because they do not want a woman about the establishment. We shall not quarrel with them, that is their privilege. On the other hand, there must be quite a proportion of druggists who have not given the question serious thought, at least from the point of view of their women patrons and the advantage in the way of increased business. It might be only necessary to bring the subject to their attention, to let them know that women are thinking about it, that women want it. Fair-minded individuals would be likely to investigate and honest consideration would convince some, not because they are so eager to grant women's requests, but because it is a plain business proposition. Women would not make such a request if it were only a passing whim. They believe that the druggists would reap some benefit as well as please them.

It is only right that it be made plain that eighty-five *per cent.* of the general merchandise sold is purchased by women and that something like the same percentage could hold with a druggist's wares. In the face of such a fact, druggists ought to see the importance of pleasing women; if a woman pharmacist is a factor in making satisfied customers, there should be no hesitancy in employing her. It is unquestionably true that lack of women pharmacists drives women to department stores for all sorts of sundries like toilet articles and toilet preparations and rubber goods that are legitimate sidelines for a druggist. Once there, they are led to buy drugs also. The pharmacy that numbers among its employees

a woman should get both the drugs and the sundry business of these people. There could be no objection to a druggist advertising the fact that his force includes a woman. Of course, it should not be sensational in character, but it is certainly proper to call the attention of women patrons to her presence. Possibly an announcement by letter might be excellent. It would only be necessary to say in a few well-chosen sentences that she is a competent pharmacist and that she is there to serve the woman patrons.

In any appeal to men-druggists, the Women's Section should assert the belief that every pharmacy in America employing more than one clerk, and even some of those should have a woman. We must concede that a druggist in a small town where paints and oils and wall-paper are handled, must have a man, unless he wants to do all that work himself. But if he does not deal in sundries requiring for their handling considerable more strength than women possess, even in a village a woman pharmacist would be desirable. In fact, I am inclined to believe that country women and women in small towns might appreciate a woman pharmacist more than their city sisters because they are possibly more reticent if not more modest than women of the cities. In the larger pharmacy employing several people, the proprietor can have no good excuse for not having one woman—no good excuse; he may offer many that seem good to him, but if he is conducting a decent honorable business, that very business would be increased by having a woman. If his business is not honorable and clean he does not need a woman, for he will have few women patrons. Women soon learn to avoid the saloon drug store or the one that has had a reputation for catering to "dope fiends"—usually one and the same.

Now and then I hear the statement that women are not loyal to their own sex, that they do not have faith in their professional ability. For instance, it is said that a woman who is seriously ill wants a man physician, even though she is in the habit of consulting a woman physician for minor ailments. If this be true, then it would be natural to conclude that women would not have faith in the capability of the woman who compounds her prescription, for the medicine may involve life or death as truly as the physician's diagnosis. Following the reasoning to a logical conclusion, all of the preceding appeal is in vain, but of that I cannot judge. If the idea has merit, it may bring results; at any rate, it may do no harm.

---

#### SENNA DRUG TRADE DIVERTED.

The export of senna from Egypt has been prohibited except to the United Kingdom and France. This measure is expected to center in London the trade in this useful purgative drug. The United States has been importing 2,500,000 to 3,000,000 pounds of senna leaves yearly. The Alexandrian senna commands the highest price, the March, 1915, quotations in New York City being quoted at 35 to 40 cents per pound for whole leaves. The Tinnevelly leaves from India are quoted at 16 to 17 cents, while pods are priced at 6 to 7 cents per pound. The Egyptian senna leaves are derived from *Cassia acutifolia*, which grows in Nubia and Kordofan, while the Indian or Tinnevelly leaves are derived from *Cassia augustifolia*.—*U. S. Commerce Reports*, No. 63.

## Proceedings of the Local Branches

### BALTIMORE.

The March meeting of the Baltimore Branch of the American Pharmaceutical Association was held Wednesday evening, March 17, in the Hynson, Westcott & Company assembly room at Charles and Franklin Streets, with President E. W. Hodson in the Chair.

The Executive Committee reported in regard to publicity for the Harrison act, that interviews had been held, conferences had been attended, letters had been written, copies of the law had been sent out, personal talks had been made and that the daily papers had printed lengthy and frequent articles about it, so that it was considered that everyone concerned should be informed as to its workings.

It was also brought out that the internal revenue officials had ruled that doctors need only sign their surnames in full to prescriptions and that initials would do for their given names.

The regular program was "Factors from Facts," the Secretary presenting a few factors which have been of considerable value in the day's work, both as time-savers and short-cuts. Little journeys were made through four of the Drug Journals by Messrs. Neal, Meyer, Morgan and Lowry, it being the intention to present one or some of the important items from the journals each month.

Mr. Lowry read extracts from a paper which had been presented to the Association and explained, that, as the part read contained some factors, the use of which might have a tendency to postpone the exclusive use of the

the safest factors to facilitate the use of U. S. P. and N. F. or any formula in the Metric system, were the weights and measures themselves. Yet, when we buy by the ounce, pound, pint and gallon and sell in the same old-styled, cumbersome but popular, customary, ever-present and always-with-us way and have to figure out cost, profit and selling price on the same basis, the old way is very convenient. If we need exactly one gallon of a preparation and make four thousand cubic centimeters, multiplying the one thousand formula by four, we will have almost a half pint too much.

The factors presented were multiplying ones and were intended to be used when the formula called for 1000 cc. of finished product.

A gallon is equivalent to 58418 grains, or 61440 minims.

If a formula for a gallon of a preparation calculated for 1000 cc. is wanted, all that it is necessary to do, is to point off three places in either of these two figures and multiply the quantities in grammes by 58.418, the product will be in grains, which can be reduced to avoirdupois pounds, ounces and grains; and to multiply the quantities in cubic centimeters by 61.44, the product will be in minims, which can be reduced to pints, fluid ounces, drachms and minims.

If tables be kept of the number of grains or minims in each ounce from 1 to 16, as well as tables by 500's from 500 to 7000 showing the equivalents in ounces and grains and in fluid ounces, drachms and minims, the conversion becomes easy.

For pints, divide either of these factors by 8 for quarts by 4, for a multiple number of gallons, multiply by the number of gallons wanted.

As an example, the U. S. P. formula for Syrup Orange Peel was cited. To make one gallon take,—

Tincture Sweet Orange Peel....	50 cc.x	61.44	3072 mn.=6 oz.	192 min
Citric Acid .....	5 gm.x	58.418	= 292 gr.	= 292 gr.
Magnesium Carbonate .....	10 gm.x	58.418	= 584 gr.	= 1 oz. 147 gr.
Sugar .....	820 gm.x	58.418	= 47903 gr.	= 6 lb. 13 oz. 215 gr.
Water, a sufficient quantity to make	1000 cc.x	61.44	= 61440 min.=1 gal.	

Metric system, that the parent body in its wisdom thought it best not to publish this part of the paper.

He uses them regularly and finds them so convenient, that he felt others might also find them useful. He said that he realized that

Mr. Meyer mentioned that a quick way of approximating the price of a single item which has been priced by the gross is to multiply by .007. Example,—price \$30.00 per gross,  $30 \times .007 = 21$ , or 21 cents.

A gross of an item priced at the thousand

will cost practically 1/7 of the thousand price. Labels costing \$2.80 per M will cost about 40 cents per gross. 1/7 of 2.80=40.

In reviewing the journals, the article which seemed to create most interest was one entitled "The Gold Mines of Pharmacy."

This caused quite a lengthy discussion. Mr. Hynson remarked that pharmacy *per se* is better now than in the so-called "good old days," and is on a higher plane and that the men engaged in it are of as high a class as they ever were, but that it is the environment of pharmacy that has caused so many to misjudge it.

In the so-called "good old days," it was associated with paints and putty, oils and glass, *et cetera*, and now it is associated with so many diversified interests that in many cases the drug stores of to-day are, in reality, department stores and, although the environment is different, yet the pharmacy in these stores is, as a rule, conducted on a high plane, and in some of these the pharmacy department is almost ideal.

Mr. John F. Hancock, who began his apprenticeship January 30, 1854, talked of what he believed were the "good old days," and grew quite reminiscent, naturally having a very deep feeling for the men with whom he had been associated.

Mr. Meyer and Mr. Schulze both emphasized that the head of the store should set the standard and be a good example both for the clerks and the public, and Mr. Morgan sized up the situation accurately when he arose and ended the discussion by saying: "The proprietor should be the pacemaker."

In criticising answers given by the journals to some of the queries, it was pointed out, that in many cases the answers show a lack of real knowledge and are therefore misleading; one answer carried out the common misconception that ichthyol is soluble in oil while it is a water-soluble complex ammonium salt or salts.

In an effort to find a remedy for the great changes in colors in the guaiac, honey and acacia mixture rather much used in Baltimore, it was suggested that the acacia be heated to 100° C. (212° F.), thus destroying the oxydase, and while this treatment would kill the ferment, it would not effect the emulsifying properties of the gum. The same treatment was suggested for drugs containing ferments which were useless medicinally and

which caused trouble or decomposition in the finished product.

The mentioning of guaiac in this prescription caused Mr. James Hancock to say that he rejected a large shipment of the resin which contained 37 *per cent.* of "exhausted tolu."

Attention was called to a new insecticide, Para-Dichlorobenzene, which has been given the O. K. by the United States Department of Agriculture. It is a non-inflammable and inexpensive crystalline substance which readily vaporizes, and as this vapor is heavier than air, it is placed above the articles to be treated, the vapor penetrating to the bottom. It ranges from 23 cents a pound in 5-pound lots to 15 cents a pound in barrels.

In discussing cold creams, it was pointed out that the solution of borax should be heated to boiling and the melted fats should also be hot, the hot borax solution should be added to the hot liquid fat and the mixture beaten till cold. Ointment of rose water of the Pharmacopœia made this way was much superior to one made by strictly following the directions. No change in the formula is necessary.

WM. J. LOWRY, JR., Secretary.

<>

#### CHICAGO.

The March meeting of the Chicago Branch held Tuesday evening, March 16, was attended by a large number of druggists, the attractive feature being a discussion of the operation of the Harrison Anti-narcotic Law lead by the Deputy Collector of Internal Revenue at Chicago. Deputy Collector Mahany read the most recent rulings from the Treasury Department at Washington and answered many questions. He stated that more than 12,000 applications for registration had been filed at the Chicago office, that the extra work involved had nearly swamped the office force, but that they would soon have things running smoothly. A number of additional inspectors have already been appointed and a strict enforcement of the law is certain.

In the discussion two points were brought prominently forward: First, the tendency on the part of newspapers to unjustly stigmatize pharmacists as "dope sellers," and, second, the very exaggerated exploitation of "doping" by the newspapers to furnish "scare-heads." As President Craig put it, "every crime in

the calendar from chicken stealing to murder is ascribed to 'dope' using or to 'dope' fiends."

Dr. Beal presented a resolution to the effect that the Branch formally protest against a statement published in the Chicago Tribune over the name of Dr. W. A. Evans. This statement, quoted from *The Pharmaceutical Journal*, was ascribed to a druggist and was to the effect that for every ounce of laudanum used in compounding physician's prescriptions, he sold a gallon over the counter, mostly to dope users. Dr. Beal said that this condition was certainly untrue of American pharmacy and unjust to American pharmacists and that because a few unscrupulous or criminal druggists sold dope was not a reason why all professional pharmacists should be so condemned. No more so than that because ten thousand persons are arrested, charged with crime, every year in Chicago, every inhabitant of Chicago should be stigmatized as a criminal. The statement of one druggist in England to the effect that he sold dope should not be applied to American Pharmacy, and, furthermore, Dr. Beal strongly questioned whether this statement by any means represented a general condition of British pharmacy.

William Loesch, speaking for the Economical Drug Co., stated that his firm filling more than 400 prescriptions daily, used but two gallons of laudanum in 1914.

James H. Wells, also in the loop district of Chicago, affirmed that his store used less than one pint of laudanum annually.

W. K. Forsyth, in the business district of the South Side, stated that he used less than one gallon of laudanum yearly and that most of this was employed in one physician's prescriptions for liniments and that he sold no laudanum over the counter. C. E. Storer, a North Side druggist, uses annually less than one-half gallon of laudanum, and this mostly in veterinary prescriptions. S. K. Sass, a prominent West Side pharmacist, uses not more than 1500 cc. of laudanum annually, and this exclusively in prescriptions, and these largely liniments. Never sold any over the counter.

These statements and other similar ones made by pharmacists in attendance at the meeting were all positively affirmed to be true, and so far as their experience went the same condition is true in most of the other

drug stores. Furthermore, the city code prohibits the sale, except upon prescription, of opium and its alkaloids, cocaine and other narcotics, and during the past year, despite the fact that a vigorous investigation has been carried on so that most of the eleven hundred drug stores in Chicago have been visited, the inspectors have been able to convict less than twenty druggists for violation of this law.

Dr. Beal's resolution was unanimously adopted.

E. N. GATHERCOAL,  
Secretary.

<>

## CINCINNATI.

The monthly meeting of the Cincinnati Branch took place at Lloyd Library, Tuesday evening, March 16, 1915.

The meeting proved a very interesting and enthusiastic one and was well attended by the members and their friends.

A special feature of the meeting was the presentation of a highly interesting paper by Dr. John Ranley, entitled "Relations Between Doctors and Druggists."

The way the doctor discussed the Theory and Practice of Ethics from the medical as well as the pharmaceutical view-point was instructive to the appreciative audience, and it led to a spirited discussion, in which a number of members took part.

Prof. Theo. D. Wetterstroem followed with "A few simple tests," same tests being capable of being applied by the pharmacist, and being mostly dependent upon the physical senses: Smell, sight, taste, hearing, touch, as well as the solubility, color reaction, chemical reaction, rotation and refraction of light. Of special interest may be mentioned the applied tests for fixed and volatile oils, as well as those determining mineral oils in linseed or similar oils.

The paper of Prof. Wetterstroem was appreciated by the members and, upon motion, was referred to the Committee on Progress of Pharmacy for further discussion.

The President appointed the following Nominating Committee, with instructions to report at April meeting: William Lakamp, Louis Werner, Fred W. Weissmann, Chairman.

CHAS. A. APPEYER,

Secretary.

## DETROIT.

The fourth meeting was addressed on March 19, by Prof. C. W. Edmonds of the University of Michigan on the subject of "Twilight Sleep." Professor Edmonds' talk was extremely interesting and was listened to very intently by all present.

He traced the history of this treatment from the use of morphine and scopolamine by Dr. Schmeidburg as a surgical anæsthetic in 1900, to its application for obstetric purposes in 1902, and the development of the method since. Articles on the subject in popular magazines were referred to as sensational and misleading. The alleged difference between scopolamine and hyoscine he thought had no foundation in fact, and that differences in effects are more probably due to personal characteristics and the frequency and amount of the doses.

The pharmacology of the treatment was described in detail, then general conclusions drawn from a study of about 800 cases as to its value.

The method is designed to destroy the memory of pain rather than to entirely deaden the pain itself, and when properly used, this effect is reached. The mother comes through the ordeal with less exhaustion and probably less suffering than without it. It needs continuous watching by the physician, however, and sometimes induces delirium, and so is not adapted to use outside of hospitals.

The effect on the child is more questionable, since the scopolamine narcotizes the reflex centers and hinders breathing, and a few cases of the death of the child have occurred due to its use. It probably lengthens the time of labor, and increases the need of the application of forceps.

The paper was discussed by Drs. Judd, Kamperman and Bell, who agreed in general with Prof. Edmonds' conclusions. Prof. Schlotterbeck discussed the question of the identity of hyoscine and scopolamine, and declared that there is no ground for considering them anything but identical.

The next meeting of the Branch will be addressed by Prof. V. C. Vaughan on the subject of "The Poisonous Group in the Proteid Molecule." This will be a joint meeting held on April 19 in conjunction with the Wayne County Medical Society, and the Detroit Retail Druggists' Association.

WILBUR L. SCOVILLE, Secretary.

## NEW YORK.

The regular meeting of the New York Branch was held in the New York College of Pharmacy Building, February 8, 1915, President Roemer in the chair.

After dispensing with the reading of the minutes of the preceding meeting, the Treasurer's report was received with thanks. Mr. McEhlenie reported that the Council had referred the election of an editor for the Journal to a special committee and asked for instructions. The following resolution, "That it is the sense of the Branch that its representative in the Council cast his vote for the candidate for Editor of the Journal recommended by the special committee having the matter under consideration," was adopted.

The chairmen of the committees on Membership, Legislation and Education, and Fraternal Relation being absent, no reports were received.

Dr. Diekman, Chairman of the Committee on Progress of Pharmacy as usual had a very interesting number of abstracts. Among others he read the following: Distinguishing between natural and artificial camphor, a criticism of the methods of identification and purity of *Cera flava* of the P. G., detection of caramel with phenol-sulphonic acid, a new method for melting point determination of fats, a method for the estimation of boric acid in ointments, the stability of phosphorous when dissolved in fixed oils, cod liver oil as a remedy for insect bites and its uses in destroying the mosquito, misbranding of codein tablets, as well as a list of recent foreign proprietaries.

Mr. C. O. Bigelow as Chairman of the "Mayo Dinner" Committee reported that a surplus of \$1.55 was on hand. The committee was discharged with thanks and the surplus ordered turned over to the treasurer.

A communication from the Board of Estimate of New York City referring to the standardization of pharmaceutical conical graduates was received.

Dr. Jacob Diner of Fordham University then read a paper on "Serum Diagnosis."

The speaker briefly reviewed the progress of serum diagnosis, beginning with the work of Gruenbaum and Gruber, the results of which led up to what is now known as the Widal reaction for typhoid fever.

After discussing the theory of agglutination and the technic of the method, with some explanation as to how to obtain the serum,

and how to interpret results, the speaker led up to the second important step in serum diagnosis, viz.: the Wasserman reaction for the diagnosis of syphilis. The theory and technique were explained in detail, particularly the line of reasoning and experimentation that led up to the use of the so-called cycles or systems. After describing in detail the three essential factors necessary to produce hemolysis, viz.: 1, the blood corpuscles of the same species which were used for immunization, called *antigen*; 2, the specific immune bodies created by the immunized animal after frequent injection of that particular antigen, called *amboceptor*; 3, the substance destroyed by heating the immune serum (thermolabile) and restored by the addition of normal, non-immune serum, from animals of the same species, called *complement*; the speaker demonstrated how the reaction is carried out.

Brief mention of the work done by McDonagh and Klein in their application of the foregoing principle to the diagnosis of gonorrhea was followed by the description of the Abderhalden reaction first used to diagnose pregnancy in its early stages, based upon the presence or absence of ferments in the blood of the patient capable of digesting albumins and thus causing them to become dialyzable. This reaction is now largely being used in the diagnosis of cancer.

The very interesting paper was discussed at length by Messrs. Weinstein, Hohman, Roemer, Wimmer, Raubenheimer and Mayo.

Many queries were answered by the author. A rising vote of thanks was then extended to the latter.

During the transaction of routine business, President Mayo of the parent association entered, accompanied by Professor Hynson of Baltimore. They were given a rousing reception and responded with some very apt and well-chosen remarks.

JEANNOT HOSTMANN,  
Secretary.

#### NORTHWESTERN BRANCH.

The March meeting was held at the Nicolet Hotel, Minneapolis, Thursday evening, March 18, 1915. The meeting was preceded by a dinner and by a brief business session of the Minneapolis Retail Druggists' Association. As this was the annual meeting of the Branch, reports were received from the various officers, and the annual election took

place. Secretary Newcomb reported briefly upon the work of the past year and referred to the sixteen new members acquired by the Branch since the last annual meeting.

The Nominating Committee reported the following names as nominations for office during the coming year: President, A. D. Thompson, Minneapolis; Vice-President, Truman Griffen, Minneapolis; Secretary-Treasurer, E. L. Newcomb, Minneapolis; Executive Committee, F. A. U. Smith, St. Paul; F. M. Parker, St. Paul; S. W. Smetana, Hopkins; A. J. Kline, Minneapolis. The names as presented by the committee were unanimously elected.

By motion the Branch voted an assessment of \$1 upon each active member to defray the expenses of the Secretary in connection with the sending out of meeting notices, etc.

Communications were read concerning the preliminary report of the Transportation Committee and copies of the report were distributed among those present.

The Branch concurred in the resolution concerning the death of Mr. Frank W. Klenert, adopted earlier in the evening by the Minneapolis Retail Druggists' Association.

The regular program for the evening was as follows:

1. The Assay of Spiritus Aetheris Nitrosi and Acidum Hydrochloricum Dilutum, with demonstrations. By Prof. G. Bachman.

2. A continuation of the discussion on Spiritus Aetheris Nitrosi, Acidum Hydrochloricum Dilutum, etc., begun at the Scientific Section meeting of the Minnesota State Pharmaceutical Association. The best methods for the preparation and preservation of the above-named products.

3. The latest rulings on the Harrison Anti-Narcotic Law.

4. The State Anti-Narcotic Bill and its provisions.

Professor Bachman's demonstration of the assay of Sweet Spirit of Niter was highly appreciated by the members present and elicited many questions. The apparatus designed by Prof. Frank N. Merck was exhibited and its use demonstrated. Prof. Bachman submitted the following concerning Sweet Spirit of Niter and urged each pharmacist to give strict attention to this preparation in order that the physician may obtain the result which he has a right to expect:

1. Do not make up more than the quantity

sold within a month. Buy the concentrated Spirit Niter, preferably in hermetically sealed tubes. The contents of one of which will make a pint of Sweet Spirit of Niter.

2. Keep the Spirit in completely-filled bottles in such sizes as are usually called for by the trade and these should be stored in a cool place protected from light.

3. Air space in the bottle has much to do with the decomposition of the Spirit.

4. Do not expose the spirit to sunlight, as this is one of the chief causes for spoiling.

5. Amber-colored bottles afford good protection to the Spirit.

The paper by Prof. Bachman was discussed by Messrs. Griffen, Frost, Pres. Thompson, Dean Wulling, Schmidley, Kline, Danek and others. Mr. F. A. U. Smith explained in detail the reasons why amber-colored bottles afford a protection to the substance contained therein, which are susceptible to the actinic rays of light. Attention was called to the indiscriminate use of blue bottles for preparations which should receive the greatest protection from chemically active light rays.

Following this discussion, the matter of a joint meeting between Twin City physicians and Twin City pharmacists was brought up and after discussion, the following motion was unanimously passed: "Moved by Dean Wulling, seconded by Mr. Frost, that the Secretary be instructed to communicate with the Chairman of the Minneapolis Retail Druggists' Association and the Chairman of the St. Paul Druggists' Association, requesting each to appoint one pharmacist, who with a member of the Northwestern Branch, A. Ph. A., to be appointed by the President, are to constitute a committee of three to bring about not later than early May, a joint meeting of pharmacists and physicians of Minneapolis and later a joint meeting of pharmacists and physicians of St. Paul, the committee to have power to make necessary arrangements."

Mr. John P. Jelinek, Chairman of the Legislative Committee of the State Association, spoke on the state anti-narcotic bill and its provisions and urged the support of the Branch for the passage of the bill by the 1915 session of the Minnesota legislature. After some discussion, the bill was endorsed by the Branch.

About 50 attended the dinner and meeting.

E. L. NEWCOMB,  
Secretary Northwestern Branch.

## PHILADELPHIA.

The regular monthly meeting of the Philadelphia Branch was held on Tuesday evening, March 9, at the Temple College of Pharmacy.

President E. Fullerton Cook called the meeting to order at 8:30 p. m. The minutes of the last meeting were read and approved.

The Treasurer reported receipts \$99.50, expenditures \$40.75, balance of \$58.75.

Mr. Thum moved that the Treasurer's report be accepted. The motion carried, and Messrs. Quintus Hoch and J. Atlee Dean were appointed as a committee to audit the books.

The program of the evening was then taken up and Prof. Joseph P. Remington gave an illustrated description of the U. S. P. IX in various stages of its revision.

Prof. Henry Kraemer discussed "The Botany and Pharmacognosy of the U. S. P. IX."

Prof. Charles H. LaWall gave a summary of the changes in "Standards and Tests for Inorganic Chemicals in U. S. P. IX."

Dr. Robert P. Fischelis presented "The Current Review of Pharmaceutical Journals."

After the program had been concluded, Prof. F. E. Stewart introduced the following resolution:—

Resolved, That the Philadelphia Branch of the American Pharmaceutical Association hereby suggests to the Senate and House of Representatives of Pennsylvania that further legislation regarding the sale, possession, distribution and dispensing of habit-forming drugs be held in abeyance until a proper trial shall be given to the recently enacted Harrison Law intended for the control of the same, and that therefore further action regarding the bills now before the Senate and House relating to this subject be postponed in accordance with this resolution, and

Resolved, That a copy of this resolution be sent to the several state medical, pharmaceutical and drug organizations asking their co-operation in securing the postponement of further legislation regarding habit-forming drugs until the Harrison Law has been properly tried out as aforesaid.

The resolution was seconded by Prof. Remington and passed by ballot.

The Committee on Nominations was called upon for a report, and Mr. Joseph W. England, Chairman, presented the following report:—

Your Committee on Nominations would respectfully recommend the following nominations for 1915-16:—

President—S. C. Henry.  
First Vice-President—J. W. Sturmer.  
Second Vice-President—W. G. Neebig.  
Secretary-Treasurer—J. Ed. Brewer.

## COMMITTEES.

Practical Pharmacy—Charles H. LaWall, Chairman, O. W. Osterlund and J. C. Peacock.

Membership—A. J. Staudt, Chairman, Quintus Hoch, Frank E. Morgan.

Professional Relations—William L. Cliffe, [Chairman, Francis E. Stewart, M. D., and Franklin M. Apple.

It was moved and carried that the President be instructed to cast the ballot for the officers as submitted by the Nominating Committee.

Prof. Remington introduced the new officers, preceding his introduction, with a short eulogy of each. The meeting then adjourned.  
J. ED. BREWER, Secretary.

## PITTSBURGH.

The February meeting of the Branch took place too late in the month to permit of its proceedings appearing in the journal of that month.

Dr. Blumenschein referred to the action taken at a former meeting, at which time a resolution was adopted instructing the Secretary to communicate with the distributors of Creolin-Pearson calling attention to the erroneous practice of labeling that article "Non-Poisonous," and exhibited at this time a bottle of the article from which these misleading and dangerous words were omitted, which Dr. Blumenschein said shows the usefulness of our taking up such matters and acting upon them.

A communication was read from Mr. P. Henry Utech, of Meadville, Pa., offering to present an interesting paper at an early meeting upon the subject, "European Pharmacy and Pharmacists," based upon his travels with the German Apothekers Verein, in 1911. It was accepted with thanks, and Mr. Utech will present his paper at the April meeting.

Dr. Emile F. Krapf, of the Radium Co., of Pittsburgh, was introduced as the speaker of the evening, his lecture being on the subject of Radium, with illustrations covering many features of the production of that substance, and it proved to be the most valuable and intensely interesting talk the members have ever been favored with. The source, manner of securing the carnotite ore, pitchblende and autunite, method of applying radium in the treatment of disease, and the use made of

Radio-active-Earth in plant growth and crop production were described. He also exhibited specimens of radium and made numerous tests of its powers. The radium facts presented were, as epitomized;—Discovered in 1896 by Madame Curie; the half life period of radium is 2000 years radium emits three rays known respectively as alpha rays, beta rays, and gamma rays; alpha rays are positively charged helium atoms, shot out with a velocity of 12,000 miles per second, beta rays are negatively charged particles, about 100 times as penetrating as the alpha rays and are of the same type as the cathode rays; gamma rays are analogous to X-rays, but more penetrating than the X-rays produced in a hard vacuum tube. Radium is extracted from carnotite ore, pitchblende and autunite. One gram of radium element represents about 400 to 800 tons of carnotite ore; seven hundred tons of chemicals, exclusive of water, are used in extracting one gram of radium. Twelve grams of radium element is the annual output of the Standard Chemical Co., of Pittsburgh, many times the entire European output. The price per gram of radium element is \$120,000 to \$160,000. Dr. Krapf exhibited numerous samples of ores, radio-active-earths, also clocks and watches the hands and figures being treated with radium so that the time can be readily seen in the darkest room.

A general discussion of the Harrison narcotic law was opened by Mr. Andrew Campbell, which threw much light on the law's provisions and its application.

Dr. George W. Kutscher, the new President, was inducted into office and in his inauguration talk promised to eliminate all the dead timber among the membership and utilize the live ones to the limit.

The March meeting on the 12th was treated to a very excellent paper by retiring President Andrew Campbell on the subject, "Hydrogenated Oils," from which we make but a short excerpt:

"Much has been reported and written about the possible wonderful cheapening of soap-makers' materials, but this has been considerably exaggerated, at least for the immediate future. . . . As the process becomes better developed and more widely used very material reductions in price of the products may be reasonably expected. . . . The two greatest apparent fields of usefulness for such

a process seem to be the production of edible fats and the bringing into range of soap-making materials vegetable and animal oils which have hitherto been unavailable on account of the relative softness of their products or for certain other technical reasons. Hardened oils will probably find other wide uses in the arts, for example in the manufacture of lubricants, but for the present the production of edible fats and of soap-making materials is of paramount importance in the development of the process."

BENJ. E. PRITCHARD, Secretary.

<>

#### ST. LOUIS.

At the March 19th meeting of the St. Louis Branch, Dr. H. M. Whelpley presented a paper on "How the Pharmacopœia is Revised." The paper was discussed by Francis Hemm, Leo Suppan, Julius C. Hoester, William Thaler, Carl T. Buehler, Miss Lydia Batdori and J. W. Mackelden.

JULIUS C. HOESTER, Secretary.

<>

#### WASHINGTON.

The City of Washington Branch held its regular monthly meeting at the National College of Pharmacy, Wednesday, February 24, 1915; the subject for discussion was the Harrison Law and the regulation for the enforcement of same.

Mr. P. S. Talbert, Chief of the Law Division of the Internal Revenue Bureau; Dr. B. R. Rhees, who has immediate charge of the enforcement of the law, and Dr. O. B. Adams, Chief Chemist, Internal Revenue Bureau, were present and discussed the law and the regulations from the view-point of its enforcement.

After going into the history of what led up to the enactment of the law by Congress, Mr. Talbert gave figures showing that the annual importation of opium, its salts and derivatives for the past 10 years had been about eight times more than what is required for legitimate medicinal purposes and that of cocaine and its salts more than double all conservative estimates as to legitimate requirements. The Harrison law was discussed as to the manner of its enforcement by the Internal Revenue Bureau and he said he felt sure that highly desirable results would follow and develop the way for improvements in the future. He further expressed himself

as highly gratified with the hearty coöperation of the trade generally.

Dr. Hubbard, chief of the division, that drafted the regulations, was unable to be present and his place was filled by Dr. Rhees, who made an explanation of the regulations as they affected every branch of the trade as well as the physician, dentist and veterinarian, external preparations were classed as those which were applied to the skin only and that did not come in contact with the mucous membranes whatever. The provisions with reference to registration, order blanks and inventories were so carefully gone into that there should be no question of doubt as to their provisions and what is required.

Dr. Adams spoke with reference to synthetic substitutes and explained that same could be considered from both a chemical and therapeutic standpoint, but what would be done with this question remained to be considered and determined later when regulations would be promulgated.

The members present participated in the discussion that followed and many points of value to physician and pharmacist were brought out. Joel Blanc made a strong argument in favor of a thorough trial of the law in every particular before any endeavor be made looking to amending same as has been already suggested. Dr. Kebler spoke along the same lines, and further said that the Bureau of Chemistry was in possession of much information that would be of much value to the medical fraternity if the facts were known, particularly in regard to the indiscriminate sale of habit-forming drugs in unexpected places in all of the large cities.

Dr. Henry P. Hynson took a most active part in the meeting and made a plea in closing the meeting that the indiscriminate sale and use of habit-forming drugs had long had a tendency to bring disrepute to both medicine and pharmacy and that both professions now had the opportunity, by making only slight sacrifices, to purge their ranks of such charges and elevate their respective professions. His remarks along the lines of compiling accurate records were most timely, and he made many suggestions of value as to the handling the stock of narcotics. He further stated that the law could not help but prove a blessing to physicians and pharmacists as well as a boon to humanity in curtailing the indiscriminate sale and use of habit-forming drugs.

S. L. HILTON, Secretary.

The March meeting of the City of Washington Branch was held March 24, 1915, at the National College of Pharmacy. The subject for discussion was the "Effect of the Harrison Law on the Pharmacy Act of the District of Columbia," by Mr. Alex. Muncaster, Professor of Pharmaceutical Jurisprudence, National College of Pharmacy.

His opening remarks, while usually correct, do not seem to fit in this particular case.

"Man whose privileges are curtailed by any law usually know more about the law than otherwise."

From the numerous questions that have been asked and the many inquiries made of the Internal Revenue Bureau and those connected with the drafting of the law, it would seem that this is not correct, for the reason that those affected have deferred considering this law until the same went into effect.

After taking up both Acts and discussing the main features of each as pertaining to the use and sale of narcotics, he clearly demonstrated by citing numerous court decisions relating to other laws, which would establish precedents sufficient, that both Acts could and would work in connection with each other without friction and that nothing contained in the Pharmacy Act of the District of Columbia had been repealed by the Harrison law.

Prof. Muncaster, further explained many sections of the Harrison Act and the regulations from a legal standpoint, that did much to clear the minds of those present. He said that numerous clauses of the law were apparently not as clear as was at first supposed, and that they would in the future require interpretation by the courts. As for instance, what are "synthetic substitutes?" Does this phrase apply to Cocaine, its salts or alpha or beta cocaine or any of their salts or simply to alpha and beta cocaine and their salts?

The requirement that the physician, dentist and veterinary surgeon keeping records shall note the name and address of the patient seems not to meet the situation of the veterinarian, should this not have provided that the kind of animal should be noted instead of the name and address? Then if this latter only is done, would it fulfill the requirements of the law?

The question as to whether a pharmacist could fill a prescription that was legitimate

in every way and complied with the provisions of the law and regulations, for one ounce of morphine or a large amount of any narcotic drug coming within the provisions of the Act was discussed from every view-point, the opinion expressed was, that the law contained nothing whatever to prevent the pharmacist from so doing if all of the requirements had been complied with, it would, however, no doubt cause the Internal Revenue Bureau to make inquiries and scrutinize the said physician, who would be compelled to show that the same was in the legitimate practice of his profession and not for the use by *habitues*, if in this he failed he then would be amenable to the Act and would be liable to fine and imprisonment.

The opinion as expressed by the Deputy Commissioner of Internal Revenue relative to the procedure to be followed in the selling or disposition of a business licensed under the Harrison law was also presented, it is as follows:—

"A retail dealer desiring to dispose of his entire business, should notify the Collector of Internal Revenue of this fact and the purchaser of such business should make a sworn inventory of the narcotic drugs coming into his possession and keep this on file in his place of business.

Previous to the transfer of such drugs, the purchaser should make application to the Collector for registration and the order forms he will require. The purchaser cannot make use of the order forms in the possession of the person from whom he purchases the business.

The purchaser should, upon receipt of his registry number and official order forms, make use of one of the order forms, in securing the transfer of the narcotic drugs and file the duplicate order form with his inventory.

When such transfers are contemplated, application should be made to the Collector of Internal Revenue for permission to make use of the larger size order forms, provided by the government upon which to itemize the narcotic drugs to be transferred."

Not the slightest objection was raised as to this ruling, every one present believing some such method should be followed.

Considerable discussion of minor importance relative to the Harrison law and many questions were asked that were thoroughly explained and did much to assist in carrying

out the provisions of the law, after which the meeting adjourned.

The subject for discussion at the April meeting will be, "The quality of some drugs and pharmaceutical preparations examined in the Bureau of Chemistry," by Dr. L. F. Kebler. This should be a most interesting meeting and it is expected that conditions of a startling nature will be shown as to the quality of drugs on the market.

H. E. KALUSOWSKI, President.

S. L. HILTON, Secretary.

## College and Society

### UNIVERSITY OF ILLINOIS SCHOOL OF PHARMACY.

The annual Commencement of the University of Illinois School of Pharmacy (Chicago College of Pharmacy) will be held at the new Central Music Hall, 64 E. Van Buren Street, Chicago, on Wednesday afternoon, April 28th. Professor Joseph Price Remington, Dean of the Philadelphia College of Pharmacy, will deliver the address to the graduating class. President Edmund J. James will confer the degrees. The indications are that the graduating class of 1915 will be the largest in the history of the school.

In the evening of the same day the Alumni Association will give a banquet in honor of the graduating class. A feature of this banquet will be the reunion of the classes of 1890, who will celebrate their twenty-fifth anniversary.

The annual meeting and election of officers of the Alumni Association will be held at the School on Tuesday evening, March 25th, when the arrangements for the annual banquet will be made.

The members of the senior class have had the pleasure of listening to a course of six lectures upon pharmaceutical law given by Mr. Walter A. Murray. Mr. Murray is a graduate of the school, Class of 1906, and also a graduate of law school. He was able, therefore, to present the subject from the pharmacist's viewpoint and the students were very much pleased with the results of his effort. This is the first time that such a course has been given at the School, but it is planned to continue it as a regular part of the curriculum.

### THE JERSEY CITY COLLEGE OF PHARMACY.

The series of social lectures at the Jersey City College of Pharmacy were continued on Friday, March 19th, when Dr. John Roemer, of White Plains, N. Y., delivered a splendid address on "Scientific Pharmacy" to the students of the College.

The lecturer gave a historic review of the growth of the manufacturing chemical and pharmaceutical industry, and the evolution of the dispensing doctor and the corresponding retrogress in retail pharmacy. He deplored the existing conditions in pharmacy and he severely criticised the constant growth of the "Patent Medicine" evil.

Dr. Roemer furthermore spoke on the many new laws which affect pharmacy and which not only act as safe-guards to the public health, but which furthermore place a great many restrictions and frequently unnecessary restrictions upon legitimate pharmacy. In spite of all these drawbacks the lecturer expressed the opinion that pharmacy will shortly undergo a great evolution and that scientific pharmacy is bound to come sooner or later. He advised the students of the College of Jersey City to make use of their pharmaceutical knowledge which they obtain during their course, in their future life as pharmacists. The utilization of this knowledge will gradually open up a field which at the present time has been unexplored, namely, that of Scientific Pharmacy.

The lecture was well attended by the students and the members of the Faculty of the College, and also by a number of visitors of the pharmaceutical and medical profession in Jersey City and vicinity.

<>

### THE COLLEGE OF PHARMACY, STATE UNIVERSITY OF IOWA.

On February 19th, Dean Wilber J. Teeters read a paper before the Baconian Club on the subject of Narcotics and Dope. He discussed the source, composition, official and other preparations of habit-forming drugs, and explained the attempts at the legal control of the sale of these drugs. In the latter the Harrison Act was discussed. Dean Teeters had specimens of many of the so-called patent medicines which contain habit-forming drugs to illustrate his paper. After the usual colloquium the paper was discussed at length by

members of the faculties of the Colleges of Medicine and Dentistry.

Dr. F. M. Barta, '06, has been elected President of the Cedar Rapids Branch of the Bohemian National Alliance of America. Dr. Barta is also a graduate of the College of Medicine and is at present located at Cedar Rapids, Iowa.

A very comprehensive paper on the subject "Vanilla," by Prof. R. A. Kuever, appears in the February issue of the Ice Cream Trade Journal. It is a detailed account of the nature and source, origin, habitat and distribution of vanilla beans; commercial varieties, and methods of preparing—artificial or synthetic vanillin, Vanillism; Adulteration—imitations and artificial extracts; Definition—legal investigations; standards of analysis.

This paper was given as a lecture before the annual convention of the Association of Ice Cream Manufacturers of Iowa, and also before the annual Convention of the Nebraska Association of Ice Cream Manufacturers. The former convention was held in Des Moines and the latter in Omaha.

Dean Teeters was called to Omaha a short time ago to act as a member of a visitation committee for the American Conference of Pharmaceutical Faculties at Creighton College of Pharmacy. Other members of the committee were Prof. Caspari of the St. Louis College of Pharmacy and Dean Koch of the Pittsburgh College of Pharmacy, Chairman of the Executive Board of the Conference. Prof. Koch was a guest for a day at the home of Dean Teeters before returning to Pittsburgh.

### The Pharmacist and the Law

#### SALE OR PRESCRIBING OF POISONS MORPHINE "LEGITIMATE USE."

Kentucky Acts, 1912, c. 86, makes it an offense for any registered pharmacist or licensed physician to prescribe for, procure for, or sell or dispense to any person opium or its alkaloidal salts or their derivatives or any admixture containing opium or its alkaloidal salts or their derivatives, or otherwise deal in the same for any purpose other than for "legitimate use," under a penalty of a fine of not less than \$20 nor more than \$100. An in-

dictment was returned under the statute against a regularly licensed and practicing physician, for prescribing morphine for a purpose other than for a legitimate use. The circuit court sustained a demurrer to the indictment, on the ground that it failed to charge that the morphine prescribed for and sold to the purchaser by the defendant, was an alkaloid or derivative of opium or an admixture containing opium, and the court could not judicially know or say that such was its character. On appeal, the appellate court said that, while morphine was not named in the statute, as an alkaloid, derivative or admixture of opium, it did not suppose there was a person, of ordinary intelligence or common understanding, residing in the state, but has familiar knowledge of its power as a narcotic, its deadly effect as a poison, and that it is an alkaloid or derivative of opium. The word "morphine" has as well-defined a meaning as the word "whisky" and its qualities and effects, are as well known to the generality of the people of the state, as are those of the intoxicant called "whisky"; and manifestly it would be a work of supererogation to allege in an indictment charging one with the unlawful sale of whisky, that it is a spirituous liquor or intoxicant. It was therefore held that the validity of the indictment was not effected by its failure to state that the morphine sold was an alkaloid or derivative of opium.

The defendant also insisted that the failure of the statute to define the words "legitimate use" rendered it void for uncertainty. In other words, it was argued that the statute fixed no standard, by which the physician in selling or dispensing opium, its alkaloidal salts or derivatives, is enabled to know what use of it by the purchaser would or would not be legitimate. The court, however, followed *Katzman v. Commonwealth*, 110 Ky., 124, 130 S. W., 990, where it had under consideration the validity of Section 2630, Kentucky Statutes, which regulates the sale of certain poisons by retail, and declares, in substance, that a sale or delivery of such poison shall not be made by any person, without satisfying himself that the poison is to be used for legitimate purposes, without defining the words "retail" and "legitimate purposes." A prosecution, instituted by warrant, against Katzman for violating this statute, resulted in his conviction, and he sought a

reversal of the judgment on the ground that the statute was void for uncertainty, because it failed to define the words quoted. The court held, however, that the statute was not void on this ground. It said, "It may be admitted that, although the meaning of the words 'retail' and 'legitimate purposes,' as used in the statute, are reasonably well-understood, it is nevertheless possible that there might be difference of opinion as to whether, in a given state of case, the sale of a drug was by retail or for a legitimate purpose, and it is possible that in administering this statute, it may occasionally happen that a druggist will be accused, who claims not to know what constitutes a sale by retail, or what a legitimate use of opium; and it is also possible that different trial courts and juries may not always be harmonious in the conclusions reached upon this point. But the fact that there may be occasional doubt or want of agreement on this question cannot be allowed to invalidate the statute."

The opinion then proceeded to state that a person who has intelligence enough to conduct a drug store, could not fail to know what would constitute the selling of a drug by retail or to understand the meaning of the words "legitimate purposes" as used in the statute; that the druggist must, as declared by the statute, first satisfy himself that the sale of the drug or poison, is for a legitimate purpose; and that, if he, in fact, does not know the purpose for which the poison is to be used, or has any doubt about it, then he must, in good faith, exercise reasonable care to find out the purpose for which it is bought. "The statute," it was said, "was intended to regulate sales by druggists, and when it is sought to apply the words 'legitimate purposes' to a sale of drugs or poisons by druggists, they have a technical meaning that may not be clearly known or understood by courts or jurors, and so it is permissible to allow experts to give evidence as to what is regarded by qualified druggists and physicians as legitimate purposes for which sales may be made, so that the trial court and jury may be informed as to what is recognized as a legitimate purpose, for which these drugs may be sold by those intrusted with their sale, and to whom, in a measure, is confined the knowledge as to what constitutes a sale for legitimate purposes."

The court held that this reasoning must control in the construction to be given the

words "legitimate use." The word "legitimate," in the statute, was not used in its original sense of *lawful*, but in its secondary sense of *proper* or *warranted*, as when we speak of a "legitimate conclusion," or a "legitimate argument." Morphine is sold for legitimate purposes, under the statute, when, under the facts, a druggist or doctor, acting according to the ordinary usage of the profession, and exercising ordinary care, would have made the sale. This, it was held, was a question for the jury. The judgment was therefore reversed, and the cause remanded for further proceedings.

Commonwealth v. Garhart, Kentucky Court of Appeals, 169 S. W., 514.

#### ADULTERATION—ICE CREAM DEFICIENT IN BUTTER-FAT.

In proceedings for selling ice cream deficient in butter fat in violation of the Pennsylvania Ice Cream Act March 24, 1909, it is held that the title of the act, reading, "An act for the protection of the public health and to prevent fraud in the sale of adulterated or deficient ice cream, fixing a standard of butter-fat for ice cream," gives sufficient notice of the contents of Section 4, which provides that "no ice cream shall be sold within the state containing less than seven *per centum* of butter-fat, except where fruits or nuts are used for the purpose of flavoring, when it shall not contain less than six *per centum* of butter-fat." The act was held to be within the police power of the state, though ice cream below the standard set, is not injurious to health. Ice cream, it was said, enters so largely into the food supply of the public, as to have become a proper subject of legislation, especially in view of the opportunities which its manufacture affords to practice imposition. In the popular understanding, it is largely composed of milk of which butter-fat is an important constituent. If by the exercise of ingenuity, and by the practice of unwarranted thrift, a product can be put upon the market having the name and appearance of ice cream, but lacking the chief element which gives it value as an article of food, a large opportunity would be afforded to dealers in that article to profit by deception, and it is the opportunity for such deceit of which the police power takes notice and seeks to take away. "It has been the policy of this state," said the court, "to legislate on the sub-

ject of milk and milk products, and statutes have been enacted which made it unlawful for any person to sell milk which contained less than a fixed percentage of butter-fat and less than a fixed percentage of mixed solids, making it unlawful to sell cream which contained less than a fixed percentage of butter-fat which classified cheese and fixed the percentage of butter-fat which the various classes of cheese should contain; and similar legislation has been enacted in other states. Legislation of a like character is found in the act of May 21, 1901 (P. L. 275), forbidding the sale of vinegar which contains less than four *per cent.* of absolute acetic acid. If the sale of pure milk containing less than three and one-fourth *per cent.* of butter-fat may be prohibited, it is not apparent why the same principle does not apply to ice cream. Milk is a natural product—wholesome and useful for food. The milk of many cows contains less than three and one-fourth *per cent.* of butter-fat. The owners of such cattle have a constitutional right to sell the product of their dairies; but this right has been held to be subordinate to the public welfare, and this welfare demands that a fixed minimum standard of butter-fat shall exist in the whole milk sold in this commonwealth. The known disposition of some dealers to cheat, and the opportunity afforded them by the absence of some regulation of the business, is the justification of such legislation under the police power." Although the dairy and food commissioner was specially charged with the enforcement of the provisions of the act, it was held that a prosecution thereunder need not be commenced by him, but may be brought by any citizen.

It was shown by the evidence that a pint of ice cream for the sale of which the defendant was prosecuted had been analyzed and found deficient in butter-fat. It was held not error to exclude the evidence of experts to show that samples taken from other parts of the same can might show different percentages of butter-fat.

*Commonwealth v. Crowl*, Pennsylvania Supreme Court, 91 Atl. 922.

#### FOOD AND DRUGS ACT. "ADDED" DEFINED. MISBRANDING.

In a proceeding to condemn a quantity of a syrup called Coca Cola on the ground that it was adulterated and misbranded, the Circuit Court of Appeals made the following

rulings. Forfeiture was claimed under the Federal Food and Drugs Act. It was held that the word "added" in section 7 of that act, declaring that an article shall be deemed to be adulterated if it contain any added poisonous or other added deleterious ingredient which may render the article injurious to health, implies the existence of a standard, and an element necessarily used to create a standard is not added. If caffeine was the addition to Coca Cola, as the complainant claimed, what was the base? For 15 years before the passage of the act, Coca Cola had been an existing article of food. It was a compound; it had no distinctive base (unless water, by reason of its larger proportion); it was made up of water, sugar, caffeine, phosphoric acid, glycerine, lime juice, coloring matter, flavoring matter and "merchandise No. 5." The test that whether the deleterious ingredient is "added" is whether this ingredient is in its natural or in an artificial form may often be a useful aid in applying and interpreting the statute, but it cannot be applied where artificially compounded foods are under consideration. In construing clause 5 of section 7, it is necessary to consider section 8 of the act, providing that an article of food which does not contain any added poisonous or deleterious ingredient shall not be deemed to be adulterated or misbranded, in specified cases, and when so construed, the act requires a standard before there can be any added ingredient or adulteration.

The act, it is held, makes no distinction between compounds known at its date and those thereafter devised, but it does not absolutely forbid the use in any compound of any element that a jury may call deleterious. Congress, having selected and regulated the use of those things known to be particularly dangerous, has not wholly forbidden other things from which no serious danger need be anticipated. The word "added" may be construed as being used with reference to a possibly deleterious food ingredient beyond the quantity in which the ingredient is normally found in usual or customary articles of food, and no such ingredient should be considered as added, provided it is present only in the quantity in which it existed in common articles of foods generally known. So construed, caffeine is not an added deleterious ingredient of Coca Cola.

The compound known as Coca Cola was held not to be misbranded, the name being a

distinctive name of the product of the manufacturer thereof and of nothing else. "Coca" is indicative of one article, and "Cola" of another distinct article, and the combination was not descriptive of any substance or combination known until adopted by the manufacturer, and is still unknown as an appellation for any other substance on the market.

United States v. 40 Barrels and 20 Kegs of Coca Cola, C. C. A., 215 Fed. 335.

<>

#### IMPURE FOOD SERVED BY RESTAURANT KEEPER—REMEDY OF GUEST.

Action was brought against restaurateurs for damages for the injurious consequences of eating a dish of "creamed sweetbreads" in the defendants' restaurant. It was alleged that the food was "sold" to the plaintiff, and that its sale was attended with the implied warranty that it was wholesome and fit for consumption. The case being made to rest upon the existence of implied warranty of quality, if there was no such implied warranty there could be no recovery. The defendants contended that the furnishing of food to a customer by restaurant keepers does not constitute a sale, and that therefore there was no implied warranty.

A restaurant keeper, it was held, differs from an innkeeper in that he furnishes only food, or food and drink, and not lodging or shelter. In so far as the character of the service performed by a restaurant keeper and innkeeper to their respective patrons is concerned, it is the same. In neither case does the transaction, in so far as it involves the supply of food or drink to customers, partake of the character of a sale of goods. The essence of it is not an agreement for the transfer of the general property of the food or drink placed at the command of the customer for the satisfaction of his desires or actually appropriated by him in the process of appeasing his appetite or thirst. The customer does not become the owner of the food set before him, or of that portion which is carved for his use, or of that which finds a place upon his plate, or in side dishes set about it. No designated portion becomes his. He is privileged to eat, and that is all. The un eaten food is not his. He cannot do what he pleases with it. That which is set before him or placed at his command is provided to enable him to satisfy his immediate wants, and for no other purpose. He may satisfy

these wants; but there he must stop. He may not turn over unconsumed portions to others at his pleasure, or carry away such portions. The true essence of the transaction is service in the satisfaction of a human need or desire—ministry to a bodily want. A necessary incident of this service or ministry is the consumption of the food required. This consumption involves destruction, and nothing remains of what is consumed to which the right of property can be said to attach. Before consumption title does not pass; after consumption there remains nothing to become the subject of title. What the customer pays for is a right to satisfy his appetite by the process of destruction. What he thus pays for includes more than the price of the food as such. It includes all that enters into the conception of service, and with it no small factor of direct personal service. It does not contemplate the transfer of the general property in the food supplied as a factor in the service rendered.

In no other case does there appear to have been made an attempt to recover for the harmful consequences resulting from unwholesome food or drink supplied by the keeper of an inn, restaurant, or boarding house in the line of his business upon the strength of an implied condition or warranty of quality. Those which have grown out of a sale by a dealer, are not in point. There being no implied warranty as contended for, the court said that the remedy of a guest at a restaurant injured by impure food served to him must probably be based on the negligence of the proprietors.

Merrill v. Hodson, Connecticut Supreme Court, 91 Atl. 533.

#### WHERE POSSESSION OF COCAINE A MISDEMEANOR.

North Carolina Laws, 1913, c. 81, Sec. 2, makes possession of cocaine by a person other than a physician, dentist, veterinary surgeon or druggist, unless obtained *bona fide* on a prescription, a misdemeanor and declares possession *prima facie* evidence of violation of the statute. It is held that the finding by an officer, of cocaine in large quantity in a secret scuttle-hole, covered by a picture, over a kitchen door, in a house rented and occupied by the defendant, is sufficient to establish possession within the statute.

State v. Ross, North Carolina Supreme Court, 83 S. E. 307.

### Changes of Address

All changes of address of members should be sent to the General Secretary promptly.

The Association will not be responsible for non-delivery of the Annual Volume or Year Book, or of the JOURNAL unless notice of change of address is received before shipment or mailing.

Both the old and the new address should be given, thus:

HENRY MILTON,

From 2342 Albion Place, St. Louis, Mo.  
To 278 Dartmouth St., Boston, Mass.

Titles or degrees to be used in publications or in the official records should be given, and names should be *plainly* written, or type-written.

KIMBLE, J. E.,

From 1018 Glendale Ave., Peoria, Ill.  
To 1708 N. Madison, Peoria, Ill.

PARKER, G. R.,

From 22 Pocasset Ave., Providence, R. I.  
To 22 Pocasset Ave., Providence, R. I.

PIERCE, I. H.,

From Salem, Ia.,  
To Pullman, Wash., care Wash. Agri. College.

FAUNO, E. G.,

From Monte 497, Havana, Cuba.  
To 529 Cerro St., Havana, Cuba.

DAILEY, JOS.,

From Ft. McIntosh, Laredo, Texas,  
To residence unknown.

NEVILLE, ARTHUR,

From Pettit Barracks, Zamboanga, P. I.  
To residence unknown.

TYSON, L. RAYMOND,

From Homdale, Idaho,  
To Midvale, Idaho.

BEMIS, R. E.,

From 7 Concord Sq., Boston, Mass.,  
To 46 Maverick Sq., East Boston, Mass.

HORSTMANN, G.,

From 14 Mt. Vernon Ave., Mt. Vernon, N. Y.,  
To 136 S. 8th Ave., Mt. Vernon, N. Y.

REDFERN, E. S.,

From State House, Lincoln, Neb.  
To Dairy and Food Commission, Des Moines, Ia.

DADD, R. M.,

From 22 Grand Ave., Milwaukee, Wis.  
To 137 Grand Ave., Milwaukee, Wis.

HARRIS, SAMUEL,

From F. H. & A. C., No. 2, Presidio, San Francisco, Cal.  
To 3131 Washington St., San Francisco, Cal.

BURGHEIM, JACOB,

From 1019 Congress Ave., Houston, Texas,  
To 209 Main St., Houston, Texas.

MAYER, PETER,

From 19 W. Main St., Marshalltown, Ia.  
To 111 W. State St., Marshalltown, Ia.

DECEASED SINCE FEB. 18, 1915.

BEXTON, E. M.,

Omaha, Neb.

REINSTATED SINCE FEB. 18, 1915.

GILBERTSON, L. S.,

Sholomish, Wash.

FISCHER, RAY O.,

Jefferson, Wis.

### A NEW INSECTICIDE.

"Para-dichlorobenzene" is a chemical compound only recently used as an insecticide, but which, in being noninflammable and comparatively inexpensive, possesses advantages over other fumigants. The United States Department of Agriculture's new bulletin (No. 167) is entitled, "Para-dichlorobenzene as an Insect Fumigant," and points out that the compound, although deadly to insects, is harmless to human beings under ordinary conditions, and does not have an odor which clings to fabrics, as do many insecticides.

Para-dichlorobenzene is a colorless crystalline substance which evaporates very quickly as a vapor, if exposed. It costs 15 cents per pound in barrel lots.

## **Albert Benjamin Prescott**

Albert Benjamin Prescott was born at Hastings, N. Y., December 12, 1832, and died at Ann Arbor, Mich., February 25, 1905. When nine years old he had a fall which made him an invalid for several years, thus making him dependent upon an older sister and private tutors for his early education. For some time he was correspondent for the New York Tribune and later taught in the public schools near his home. In 1860 he entered the medical department of the University of Michigan and graduated in 1864. He at once entered the federal army as assistant surgeon, and was later appointed the chief surgeon of the Jeffersonville Medical Hospital. At the close of the war he returned to Ann Arbor as assistant professor of chemistry, being advanced to a full professorship in 1870. Later he received the degree of doctor of philosophy and the honorary degree of doctor of laws. At the organization of the school of pharmacy in 1868 he was elected professor of pharmacy; in 1876 he was made dean, a position which he filled until his death. He was president of the American Pharmaceutical Association in 1899-1900, president of the American Association for the Advancement of Science in 1901, a member of the United States Pharmacopœial Convention from 1880 to the time of his death, and contributing editor of the Druggists' Circular, 1884-1886. He deserves distinction as a benefactor of pharmacy during the past half century, although not a pharmacist in the ordinary acceptance of that word. It was his steadfast stand for higher and better pharmaceutical education and ethics that places him high among those that have benefited the calling.

ALBERT BENJAMIN PRESCOTT, 1832-1905

# The Journal of the American Pharmaceutical Association

### EMPIRICISM VERSUS SCIENCE.

JOHN URI LLOYD, PHAR. M.

Whoever attempts to individualize a scientific problem, becomes aware of the fact that, whatever it may be, it wedges into and dovetails with other problems from which no exact line of demarcation can be drawn.

A conspicuous example in this direction, contributed by the writer to the American Pharmaceutical Association Proceedings, 1879, is the fact that percolation and maceration cannot be, in the act of percolation, separated from each other. In fact, the very beginning of the process of percolation includes maceration, and during the process of percolation, maceration is a continuous factor. This, after an elaborate series of experiments and arguments connected therewith, the writer summed up, *American Pharmaceutical Association Proceedings, 1879*, as follows:

"In percolation, from the instant the stratum of menstruum commences to penetrate the material until it escapes we have maceration connected with alteration of the position of the mass of the liquid. There are continually new surfaces of contact formed as the liquid passes downward towards the exit of the percolator, and, as has been shown, in maceration this

phenomenon is also presented. There is no rest within the vessel while solution progresses. Mediums of greater specific gravity than the original menstruum are constantly forming, which, obedient to gravity, seek the lowest portion of the vessel, in turn to be displaced by heavier liquids. In this way during maceration numbers of percolating currents are flowing throughout the capillaries, and between the interstices of the material, as in percolation, while fresh portions of liquid are continually coming into contact with new surfaces, and saturations are giving way with perfect regularity to those not saturated.

"Thus circulation of currents progresses and will continue until an equilibrium is established, as long as there is soluble matter and unsaturated menstruum within the percolator, and afterward whenever the temperature is permitted to change. Therefore, maceration cannot be disconnected from percolation, and as we have seen, percolation must include maceration."

Let us apply the above as a text to "Empiricism versus Science," between which there would seem to be, as some view it, a clearly-cut line of division, but between which, in this writer's opinion, a sharp line of demarcation can no more be drawn, than between percolation and maceration. They, alike, wedge into each other; they dovetail, one into the other, and, each a part of the other, pass into thought and practice, even as scientific thought and study unite with empirical experimentation.

Placing ourselves, even superficially, in the position of the searchers after knowledge in days gone by, it becomes evident that, at an early date, theoretical or speculative processes gradually dominated the then scientific field, including chemical and therapeutic activity. In this direction, also, there seems to be no doubt that a connected religious process was injected, as a dominating influence, into all "material" problems, (even into such a study as entomology) in days gone by. Indeed, one needs go but a few centuries back, to discover that religious thought and complications dominated those engaged in the experimenter's field of that day, in a direction which even today is, by some, considered wholly materialistic, as though there could be any separation of matter and force, spirit and substance.

Be that as it may, there came a time when a section, at least, of the searchers in scientific directions rebelled against what were then considered ethically correct precepts, demanding that whatever was theoretically announced, must be practically demonstrated. It seems to be apparent that some of these revolutionists went even further, and proposed to establish the reverse of existing methods, by demanding that theory be subjugated to experiment, arguing, probably, that experiment established fact; that seeing a thing, was knowing that the thing existed; that touching an object proved that the object was there; that reactions between different materials were self-evident facts, and that the processes known as "Sensuous Experience," were the sole source of all ideas and knowledge. In other words, mental philosophy and theory were, by these reactionists, subjugated to what might be called the mechanical phases of elementary reactions. Thus, the therapeutic *experimentalist* demanded that all theory must be based upon experimental fact, and in contra distinction to what in medicine might be defined as an entrenched, dogmatic school, he became, himself, a dogmatic skeptic.

"Their chief point of view was that of practical observation, as opposed to the theoretical speculations of the dogmatic school." *Encyclopædia Americana*

Thus came into the early field, as resisters of theoretical "dogmatism," a class of men who, scarcely less dogmatic, demanded that experiment be made primary, and theory secondary. To these people were given the name "Empiricist," de-

defined by the *Century Dictionary* as "one who believes in philosophical empiricism; one who regards sensuous experience as the sole source of all ideals and knowledge," a definition yet employed by many authorities in the world's literature.

To state it briefly, although Locke is by some regarded as the father of modern empiricism, it is evident that from a very early date, perhaps from all time, the principles involved in what is known as empiricism, have threaded the processes of dissenters less conspicuous than Locke.

We need scarcely refer to the fact that when empiricism in medicine and connected problems wedged itself into conspicuity, it became necessary to attack the entrenchments of previously established philosophical doctrines. The resistance that naturally followed created friction, and parties often needlessly became rivals, when, in this writer's opinion, they should have been allies, engaged in a common cause, but in different lines of thought and action. Be this as it may, in the time of Celsus and Galen, physicians became antagonistic to professional methods of the past. They laid great stress on physical changes, and often illogically excluded all-important theoretical study.

Thus the pendulum swung from a dogmatism in one direction to a dogmatism in the opposite direction, although, unquestionably, thinking men of all times profited by and gave credit, knowingly or otherwise, to the practical result of the combined efforts of all concerned.

Following the dogmatism of past theoretical doctrines, came a tendency on the part of the devotees of entrenched empiricism, to be not less overbearing than had been their predecessors. Remedies were so illogically described and prescribed, by reason of isolated individual experiences, as to bring discredit on the cause of the empiricist, to such an extent that, at a period perhaps impossible to determine, the name itself began to degenerate from its original meaning. The experimenter, or empiricist, unquestionably became hopelessly lacking in the direction of systematic, reasoning opportunities. The empiricist physician, relying too implicitly on the "unprejudiced observation of Nature," and believing that such observations must lead to unalterably perfect prescriptions, thereby lost his opportunity. Once more the pendulum swung back. The name "Empiricist" carried now with it the thought of an inadequate experimenter, whether in pharmacy, chemistry or medicine, and thus, rightly or wrongly, degenerated from the ideals of the past.

Having thus touched, briefly and superficially, a few of the changes that came through great periods of time, this writer does not hesitate to declare that, for himself at least, the name "Empiricist" has no terrors, nor can the word "Science" rightfully exclude experimentation. The man of science needs be gifted in experimentation, and the man who experiments needs be trained in scientific thought and action. As the man who percolates according to modern methods unites his efforts with those of the man who macerates a drug according to preceding processes, so does the true man of science today depend upon the experimenter of yesterday.

The man involved in pure scientific reasoning, foreseeing an opportunity by reason of his theoretical knowledge, devises a theoretical process that, without having yet been instituted, he accepts must give a satisfactory, experimental end-reaction. And yet, his theoretical knowledge is probably based upon previous observations by the experimenting chemist or pharmacist, whose reports concern-

ing changes observed, give to the advancing scientist his theoretical opportunity. Had not Sir Isaac Newton followed the line of reasoning instituted by the apple that before his eyes fell from the tree, perhaps for some time the study of gravitation would have been neglected. How could the astronomer of today predict with exactness the period of eclipses of moon or sun, but for the disjointed observations made by empiricists of times gone by, who noted and recorded the coming and the passing of the periodical eclipses? Did Madame Curie theorize in advance that the waste earth experimented with in her laboratory would yield the marvelous substance, *radium*, or, with a ray of experimental light before her, did she discover that substance through careful and thoughtful experimentation? And, without subsequent experiments, could the man involved in reasoning science, have given or accepted a theoretical explanation for the wonderful phenomena that radium presents to humanity?

Thus, in any line of reasoning or of experiments, we find that one dovetails into the other; that as one advances, so does the other; that the materialist, if so you will call him, and the theorist, are dependent, each upon the other. The theorist ventures into untried, experimental fields, with the suggestive thought, based upon past experiences, that such and such an action will follow. The materialist, following his lines of systematic experimentation, in turn presents to the theorist (perhaps himself) opportunities for mind research and explanation. But, above all, each should be ready, with an open mind, to catch the unexpected, for accidental discoveries may accrue, (as in the case of Madame Curie), and be of the greatest service to humanity, as well as of the greatest interest to the theorist. Together, they become "Science."

When La Place, reasoning from calculations made by observing the motions of the heavenly bodies, directed astronomers to point their telescopes to a certain part of the heavens where never a planet had been seen, predicting that there a planet would be found, did he not, mathematically, utilize the results of empirical observation, with the same certainty that the scientific man of today utilizes the results of the recorded observations of the empiricist who brings to him the report of experimental phenomena not before observed? This writer then asks, if there be a line of division between Empiricism and Science in chemical, pharmaceutical and therapeutic action, that each should regard the other as a friend and as an ally, in the cause of professional advancement.

In the opinion of this writer, as has been stated, rational experimentation cannot be separated from systematic thought and theories, nor can theoretical science separate itself from reactions observed in materialistic directions. No opprobrium should therefore be cast upon the man whose line of activity leads him into unknown fields of experimentation, nor should any touch of satire be cast by such a man upon him who, without experimentation, moves the world onward, by his scientific reasonings and deductions.

As one who comes into close touch with many men in advanced science, but whose field of activity is largely engrossed by empirical experimentation, this writer believes that the utmost cordiality exists today between advanced men engaged in these different spheres of activity, and that the true scientist no less regards the usefulness of an experiment that for the present may seem to be fruitless, than does the thinking empiricist deny the fullest credit to the man who perhaps never practically touches a materialistic, experimental object.

## INTERNATIONAL CONGRESSES VS. THE EUROPEAN WAR.

---

JOSEPH P. REMINGTON.

---

The European war has come as a staggering blow to international work of every description. When the last shot has been fired and the dove of peace hovers over the world, it will remain to be seen whether international congresses will resume their meetings and whether these meetings will be harmonious, whether the passions of men, excited as they have been by militarism, will continue, or whether the reaction will cause men to forget the horrible disasters of the war and meet again to discuss and develop the peaceful arts.

That the United States of America may become the mediator is a "consummation devoutly to be wished." The almost unanimous feeling in this country is that the terrible carnage which now prevails should soon cease and peace and good will once more prevail.

It is greatly to be hoped that The Netherlands will escape further complications and that the *Fédération Internationale Pharmaceutique*, which has done so much in organizing scientific pharmacy throughout the world, will emerge triumphantly when peace is declared and in the rebound obtain greater influence than ever in its uplifting work.

It is a cause for congratulation that the American Pharmaceutical Association is a member of this International Federation, and surely it can be depended upon to join hands with Holland by assisting in the upbuilding work.

It is not likely that any international congresses will be held during 1915. The pharmacists of The Netherlands have had a most serious mission and they are busily engaged in raising funds to keep a large number of refugees, Belgians and others, from starving. What greater work can be done for our fellow craftsmen who have lost everything during the war?

The International Congress of Applied Chemistry, which met in September, 1912, adjourned to meet in 1915 in the city of St. Petersburg, Russia. It could not be foreseen by any one who was present at the notable meeting in New York that two years afterwards would see another side for chemical industries and death dealing explosives replacing the manufacture of health-giving chemicals to be used in the healing of the nations. The Ninth International Congress of Applied Chemistry will literally never meet at St. Petersburg, for its name has been changed to "Petrograd."

How can the "entente cordiale" be established? Many chemists and pharmacists who have been active workers in national and international science will have lost their lives in defense of their countries, but the hope is expressed that those who have been spared will be imbued with more zeal and that they will hasten to restore their fallen fortunes and recover as rapidly as possible from disastrous conditions, and that chemical and pharmaceutical activities will be resumed and fully restored. Surely this must be the hope of American pharmacists!

It will be recalled that the International Congress of Applied Chemistry ap-

pointed a commission to organize a movement to establish international standards for drugs and chemical substances with the object of establishing uniformity throughout the world by legalizing standards which will be operative in every country. It cannot be expected that these standards can be established immediately even in times of peace, and, although a start has been made, the onset of the war has prevented effective work from being undertaken.

A resolution (tenth) which was approved by the Congress is as follows:

"(a) That Section VIIb of the Eighth International Congress of Applied Chemistry consider the feasibility of International Standards of strength, purity, method of testing and nomenclature of pharmacopoeial preparations.

"(b) Section VIIb (Pharmaceutical Chemistry) of the Eighth International Congress of Applied Chemistry having received and discussed the report of the International Commission on 'Variation in the Activity of Toxic Drugs,' resolves that it is desirable that this inquiry be continued and that the International Commission be reformed and to consist of the following eight members:

"Austria, Prof. Wilhelm Mithacher; France, Prof. E. Bourquelot; Germany, Prof. H. Thoms; Great Britain, Francis Ransom; Netherlands, Prof. L. Van Itallie; Russia, W. Ferrein, Mag. Th.; Switzerland, Prof. A. Tschirch; United States, Dr. R. H. True, and the following three secretaries: G. P. Forrester, F. C. S., European continent: Peter MacEwan, F. C. S., Great Britain; Otto Raubenheimer, United States.

"(c) It is further resolved that this commission be authorized to enlist the co-operation of other persons actively interested in promulgating international uniformity of standards for potent drugs and improvement in their cultivation and collection.

"(d) That the International Commission of Congresses of Applied Chemistry be requested to approve the organization of an international committee under Joseph P. Remington, and composed of chemical experts approved by this commission, whose duty shall be to collect information from every available source on chemical products and the essential oils used in pharmacy, and to investigate the tests now in use to prove the identity and purity of said products and oils; also to consider standards and tests with the view of establishing uniformity in the same throughout the world, and to report at the Ninth International Congress the results of its work."

In addition to this, the Eleventh International Congress of Pharmacy, in September, 1913, at The Hague, appointed a commission to continue the work towards the unification of the pharmacopoeias of the world. This commission has a wide scope, but it will be observed that the objects and principles are the same as those of the commission of the Congress of Applied Chemistry. Medicines are not supposed to differ greatly in the therapeutic action upon men, women, and children, irrespective of their nationality, and many advantages at once appear if this great work can ever be accomplished.

When the war is over, commercial relations between the various countries will be vastly stimulated. Every nation will seek to repair the tremendous losses which have been incurred. International travel will be resumed on a large scale and it is believed that international standards will be sought. It is not likely that an international pharmacopoeia will ever be published, but there seems to be no good reason why these two commissions working together cannot formulate standards for the more important potent remedies to the end that there should be little or no variation in the standards of strength throughout the world. While the work is temporarily halted by present conditions, the objects are so worthy that every effort should be made to bring about a consummation.

## TWILIGHT SLEEP.\*

---

PROF. C. W. EDMUNDS.

---

During the past year there has been a great deal of interest aroused in the popular mind in regard to the use of certain drugs to lessen the pains of childbirth by the production of the condition known in this country as "Twilight Sleep." It would seem from the sudden interest taken in the subject that the method was a development of only the past few months, but, as a matter of fact, the use of nonvolatile drugs in labor dates back several years, to 1902, and is preceded by their use in general surgical work.

It was in 1900 that Schneiderlin, desiring to reduce the amount of chloroform which it would be necessary to give for an operation for cancer, preceded the administration of the chloroform by an injection of morphine and scopolamine. The results were so satisfactory that later on he increased the amount of these drugs, dispensing with the chloroform entirely. The doses used were quite large, even up to 1 1/6 grains of morphine and 1/25 grain of scopolamine in 1 1/4 hours, and he advised that in case of hurry a dose of morphine 1/2 grain and scopolamine 1/60 grain be given. He published his results in ten cases, and recommended the method highly as he considered it perfectly safe.

Two years later Blos published the results he had obtained in 105 cases, in which series there had been one death. Following these papers, the method was extensively used in general surgical work, but as statistics showing its dangers were gradually gathered, the method quite rapidly fell into disuse.

It was in 1902 that Von Steinbüchel suggested its use in obstetrics, and in his second paper he gave the details of its use in twenty cases. He used doses of 1/6 grain morphine and 1/200 grain scopolamine, which doses he said might be repeated if necessary. In contrast to Schneiderlin, the papers of Von Steinbüchel were very cautious in their tone. In the next few years the use of these two drugs in obstetrics was tested in many of the European clinics, and after a more or less extensive trial the method was given up in practically all of them. In Freiberg, however, the procedure was still used and further developed until the Freiberg method or some slight modification of it has come to be the one most generally recognized in this country.

One of the drugs which has been used is Scopolamine (which has also been named Hyoscine), an alkaloid found in *Scopolia atropoides*, *Hyocyamus niger* and other plants of the Solanaceæ. It is optically active, rotating polarized light to the left. Straub's scopolamine contains mannite in order to prevent deterioration. The other drug used is morphine or some substitute which has been introduced for it. In some clinics pantopon, a mixture of all the opium alkaloids introduced by Sahli, has been tried, but it has not given much satisfaction as it has been found to be too toxic.

More recently Narcophen has been introduced and it is being extensively used. This drug is a mixture of the meconate of morphine together with the meconate

---

\*Read before Detroit Branch, A. Ph. A., March 19, 1915.

of another of the opium alkaloids, narcotine. About one-third of the weight of Narcophen is morphine. This preparation is the one now being used in the Freiburg clinic.

Briefly stated, the method is as follows: The first injection of narcophen  $\frac{1}{2}$  grain and scopolamine  $\frac{1}{150}$  grain is given as soon as labor is well established as shown by the fact that the uterus is contracting for about thirty seconds every four or five minutes. Three quarters of an hour after the first injection, a second is given, this time of scopolamine alone— $\frac{1}{150}$  grain. The further dosage varies for each patient and is determined by repeated memory tests. This test is carried out half an hour after the second dose by showing the patient some object, or by asking the patient, for instance, how many injections she has had, or some such question, and making note of her answer. Her memory is tested twice again in like manner by showing the same object or asking the same question at intervals of half an hour; and if after the second test the memory is still retained, a third injection of scopolamine  $\frac{1}{200}$  grain is given. Further injections of scopolamine are given as necessary in order to maintain the desired end, which is the abolition of memory. The pains are perceived by the patient, at the time, but upon awakening afterwards she has no recollection of them. It is also true that in a very considerable percentage of cases there is a very distinct lessening of the pain itself.

As to the advantages of the method, it may be said that in about seventy percent of all cases there is not only loss of memory of the pain of labor but also relief from the suffering. In about ten or twenty percent more there is no loss of memory but only some relief from the pain, and in the rest of the cases the method is a failure.

In regard to the disadvantages, one of the first which may be mentioned is the complex technic necessary. It is practicable to carry it out only in a hospital, as constant attendance and absolute quiet are essentials. If it is to be done in a private home, it means the transporting of physician and one or two nurses to the house for the entire time of labor. The patient must be watched very carefully, and the child requires constant attention as its heart rate must be counted every fifteen minutes in order that labor may be terminated quickly by operative measures in case the child is discovered to be in danger.

The second stage of labor is apparently prolonged, causing increased danger to the child and making it necessary to use forceps more frequently. And finally as to the danger to the child, there seems to be no doubt but that more frequently than normal it is hard to get the child to start breathing. This applies not only to cases of true asphyxia but also to the condition known as oligopnea in which the respiratory movements are much interfered with for some little time after birth, due to the depressing action of the two drugs.

Many reports are being published which are very favorable to the method, but it is also true that there are in addition reports of the deaths of a number of infants for which no other explanation could be given, than that the drugs used in the production of the twilight sleep were responsible for them.

To summarize, it may be said that it is probably true that the condition of Twilight Sleep is in no way harmful to the mother, but that it is believed today that it involves some increased risk to the child.

AMPULS.

---

THESIS PRESENTED BY HERMAN H. NORTH, PH. G., DEPARTMENT OF PHARMACY,  
COLLEGE OF JERSEY CITY.

---

## THE EVOLUTION OF THE WORD "AMPUL OR AMPOULE."

The newer Pharmacopœias have been practically enforced to give ampuls a place by the always evident Pharmacopœia elegans, inasmuch as ampuls have lately come into extensive use.

The etymological origin of the word "ampul" in English, or "ampoule" in French, is not absolutely clear. There are two possibilities. It may have been derived from a diminutive of a Greek word "amphora," or from a lost Latin word "ambolla," compounded from "amb-olla." But the Latin and Greek languages are offsprings of an older mother language, supposedly the Indo-Germanian language. If we trace either "amphora" or "ambolla" to their original shape in the presumed Indo-Germanian language, we will find the same ideas prevalent. "Amphi" in Greek and "ambo" in Latin, mean the same and lead to the idea of a vessel having a handle on each side.

In German the development of the word "Zuber" is the same. "Eimer," from "ein-ber," meaning one handle, and "zuber," from "zwei-ber," meaning two handles, designate different vessels bearing one handle, or others bearing two handles. It is clear that originally the vessels called "amphora," needing two handles, must have been very large, and indeed they were.

We find such vessels corresponding to the denominations "amphora," in old Egyptian pictures, in excavations of Schliemann of Troy, and in some pictures and excavations of old Greece and Rome.

In some instances, this "amphora" had a standard capacity. In olden Greek times, this "amphora" had a capacity between eight and a half and nine gallons. In the later time of the Roman Empire this capacity was decreased to only six gallons.

Besides these enormous vessels, there were also small oil containers used for illuminating purposes, having chains attached to them on both sides, as parts of candelabra. These small oil lamps had two handles attached for the bearing of chains or strings, and were also called "ampulla," and therefrom originated the small hanging lamps called "ampels," which are still used in Germany, Holland, Sweden and Norway.

This word "ampul" was known two thousand years ago, as a rare word in the old Latin language, and it became more frequently used in mediæval Latin of the Catholic Church and in Medicine.

Large vessels gradually assumed a special shape. The possibility of these vessels carrying large amounts of a liquid led to a belly-shaped vessel. The possibilities of contamination by contact with the air, evaporation or spoiling while pouring out the liquid from large orifices of these belly-shaped vessels led to the construction or rather the formation of vessels having narrow necks.

Henceforth, a large vessel, flask-shaped or belly-shaped, having a long thin neck, with no handles, was the only remaining form prevalent and all other forms

and shapes were forgotten. The first perception can be traced back two thousand years ago, whence the adjective "ampullaceus," and not "ampulla," applied or rather designated a vessel as above described.

Plinius used this adjective "ampullaceus" to designate a pear which was belly- or flask-shaped, having a thick or rather broad belly and a long thin neck. During mediæval time, the pilgrims to the Holy Land used to carry water contained in flasks made from pumpkin, having the above described shape. The older shape, namely, having two handles attached to the "ampul," was lost in mediæval times for the word "ampulla" itself.

From now on, the ampul assumed the shape of a container having a large belly and a small neck, which was made from different kinds of colored glass and even earthenware and leather, and later on of pumpkin skin.

In the Latin of the Catholic Church, we find small "ampulla" holding holy oils or blood of martyrs. In Canterbury and Rheims there were "ampuls" containing holy oil used for crowning the Kings of England and France.

In the Roman Church, they have "ampuls" containing wine and water for use in mass, and others containing oils were used for different sacraments.

In Scientific Botany and Biology the word "ampulla" is often used, which in Morphology designate flask-shaped cavities.

In French "ampoulette," Dutch and Swedish "ampulette," refers to a vessel which does not have handles on both sides. It refers or rather designates a vessel, bulbous or rather bellying at each end and connected by a long thin neck, through which ran sand at certain time intervals, as for example, a quarter of an hour or half an hour, and which was called an hour glass. The sand was placed in one end of the vessel and as it ran through the neck into the other vessel, it would thereby designate the time. When all the sand ran into one vessel, it was then inverted and in this way they used to differentiate the hour, or rather the time of the day.

In modern time, the word is still used in some Romance languages; but in these languages the word has partly a "u" and partly an "o" as the original "amphora" or "ambolla."

"Ampulla," or the respective derivative word of these modern languages, means a flask, bottle, jar, pot or other vessel swelling in the middle and furnished with two handles.

The latest development was to use the word "ampoule," originating in France, designating some kind of little flask of glass with long neck and closed or rather sealed by the glass flame and enclosing volatile liquid for chemical purposes. From the "ampoule" the pharmaceutical "ampoule" have been derived. In English and German this word is generally written "ampul."

#### DISCUSSION

Among the noteworthy advancements in the preparation of medicinal agents, the ampul has attained a very important position. It has made it possible to administer with certainty accurate amounts of sterile solution of definite strength and known therapeutic value. These solutions are injected subcutaneously, intramuscularly or intravenously, but rarely by other methods of administration, as for example, ethyl chloride. The field of administration of such injections

has greatly increased because they are rapidly absorbed, while certain of them are delivered directly into the circulation. Therefore much loss of time and imperfect absorption of the medicinal agent and waste is avoided. Furthermore, gastric intolerance to certain drugs or serious tax upon the digestive organs may be mostly eliminated. Convenience and safety are the keynotes of ampul therapy, while quickness and directness of action are features deserving scarcely less emphasis. To date, no container has proven as practical as the ampul, which for evident reasons has become immensely popular with physicians.

#### HISTORY OF MEDICINAL AMPULS.

G. Pegurier says that the first ampuls were Pasteur's pipette and the sterile flask, which were suggested in the course of his researches on bacteria by a desire to obtain pure cultures by using an absolutely sterile medium and to preserve these cultures from accidental contamination by extraneous organisms.

It was about thirty years ago, that Limousin, a French pharmacist, proposed the ampul as a convenient method of preserving hypodermic solutions, while a paper describing ampuls was published in the "Bulletin Generale" of the "Societe de Therapeutique" for April, 1880.

In foreign countries, especially in France, this method of dispensing has attained its greatest popularity. In 1905 in a great many Russian pharmacies, ampules were filled by use of the hypodermic syringe or by heating and dispensed on prescriptions.

The French have made a very general use of this form of medication which is as popular in the Latin countries of Europe as the hypodermic tablet is in the United States. In time the hypodermic tablet will give way in popularity to the ampul for general use in the United States. As a matter of fact the principal danger of infection in the use of ordinary hypodermic injections comes not from the solution but from the syringe of the physician, who does not use sufficient care in sterilizing it before putting it into use.

#### FORMS OF AMPULS.

The largest ampuls on the market are the ethyl chloride ampuls. Ampuls vary greatly in capacity; large ampuls being used for massive injections of saline solutions. The form varies as widely as the capacity. The original form proposed by Limousin consisted of a round bulb with a neck drawn out to a small tube, therefore the name ampul, as explained in my introductory chapter. The dropper ampul has been introduced by many large manufacturers for dispensing chloroform. The tubes of concentrated spirit of nitrous ether and those of ethylchloride are also put up in ampul form which were originated by Bengue. A special form of ampul which can be used as a hypodermic syringe called the "Omnium Ampoule," is of French origin and is now also made by American manufacturers.

#### MANUFACTURING OF AMPULS.

##### Glass Required for Ampuls.

Tending to cover such a wide scope of uses, the ready ampuls must be fit for all kinds of fillings. The best glass that can be used for such ampuls is a neutral glass, that known as Jena Normal 10 III or that termed Fiolax glass, white or

amber, as ordinary glass contains soluble alkali, which affects the solutions therein contained. For example, ordinary glass will precipitate crystals of strychnine which may be small enough to pass through a hypodermic needle and cause great pain when injected into the tissues. For solutions which are changed by the action of the light, as ferric solutions, apomorphine or physostigmine solutions, ampuls of amber glass should be employed.

#### GLASS TESTS.

A good method to try out the glass is to fill the ampuls with a one percent alcoholic solution of phenolphthalein and boil them for about half an hour. If the solution yields a pinkish color, then the ampuls should be rejected.

In order to test for the presence of the soluble modification of silicic acid, place some of the ampuls in one hundred cubic centimeters of tenth normal potassium hydroxide solution and boil for one hour. Then concentrate it down to ten cubic centimeters. Then let it stand for twenty-four hours and if a turbid precipitate of silicic acid is formed, the ampuls should be rejected on account of the presence of free soluble silicic acid.

The Swiss Pharmacopœia directs that the empty ampuls should be rinsed with dilute hydrochloric acid, followed by distilled water with the idea of neutralizing excess of alkali.

If the ampuls are cleaned one day with hydrochloric acid, they should be washed well and cleaned for twenty-four hours with an alkali or better still, inverted, clean first with alkali and the second day with acid.

#### THE MAKING OF THE EMPTY AMPULS.

The manufacture of empty ampuls has developed into a special business both in Paris and in Thuringia, Germany. Among the leading manufacturers of the empty ampuls are Adrain and Fournier of Paris, and Fridolin Grenier of Neuhaus am Rennweg, near Jena, Germany. Where the dispenser is unable to purchase the ready-made ampuls, he can make them himself, from Jena glass tubing, if only ordinarily skillful in glass blowing.

With a little care, it is very easy to make ampuls for your own special use. Take a small Jena glass tube about half an inch in diameter. Close it at one end by heating it in a blast or an ordinary bunsen flame. Heat it again, this time further up, until it becomes soft and with a gentle pull and twist, an ampul can be made, which is as good as that made by any manufacturer.

By blowing a current of air into the side of the heated ampul, a spout is formed which is very useful for keeping and pouring out liquids. Such ampuls can be used for keeping chloroform, ergot, digitalis and strophanthus solutions. From the above, we can see that there is really no excuse for anybody saying that ampuls cannot be made because the empty ampuls are hard to obtain. With just a little tact and manipulation, one can make hundreds of ampuls within a short time.

#### CLEANING THE EMPTY AMPULS.

Place the empty ampuls into a suitable vessel of distilled water, bring to a boil, remove the flame and pour cold distilled water on the ampuls as they float in the boiling water. They at once fill themselves. Again bring to a boil, when all or nearly all the water will again be expelled. Then sterilize in an oven at 120° C.

## METHODS OF FILLING AMPULS.

The methods of filling ampuls may be divided into three classes:

1. By Gravity.
2. By Pressure.
3. By Vacuum.

Under each of the above headings, a description of the working of one instrument will be given in full, which will in all probability apply to all instruments, although differently constructed, yet working upon the same principles.

Every ampul to be filled must have a larger capacity than the contents therein to be placed. This is on account of sealing, because it is absolutely impossible to seal the neck of the ampul in the flame if the point and surrounding neighborhood is not absolutely dry, because wet glass in the flame cracks.

## BY GRAVITY.

A very simple form of gravity filler and one easily understood is a burette. As the burette is accurately graduated, it makes it very easy to measure the amount of solution put into each ampul. As the opening of the burette is quite large, compared to that of the ampul, all that is necessary to do, is either to close the opening of the burette a little by the aid of heat or else attach a piece of rubber tubing to it, having attached at one end a small glass tube.

All that is necessary to do, is to pour the sterilized solution into the burette and cover the top of it, so as to prevent any contamination of the solution. Then by placing the ampuls on a rack or holding them in the hand, the solution can be easily poured into them to the desired amount, sealed and then sterilized.

The only possible objection to this method may be the fear of contamination of the solution, but this seems to be rather untrue. If the filling of the ampuls as above described, is performed in a room where no current of air is circulating, contamination is almost improbable. In one of the universities, twenty-four hour, gelatin cultures of the air of a room were taken, and it was found to be perfectly free from any bacteria, so that the above method of filling ampuls can be carried on with absolute certainty that the ampuls will be bacteria free.

The commercial filling of ampuls should be carried on in places remote from large cities because there is less danger of contamination by germs.

A kind of multiple burette is used by Paillard-Ducatte of Paris, under the name of "Semplissodosseur." There are other modifications of the burette which are used and employ the same principles. For example, the Pegurier and the Falck stock bottles which involve more or less the same principles of gravity filling and therefore employ and work by the same method as that of the simple burette and therefore require no further explanation.

In the same way since about two decades (1896-7) Professor Alexander von Poehl of St. Petersburg filled his spermin ampuls with 1.7 cc. of a solution, which contained physiological salts in the same proportion as those found in the blood.

## PRESSURE FILLER.

The hypodermic syringe furnishes a convenient and simple form for filling ampuls. An all-glass syringe should be used for filling ampuls by this method. A syringe of this kind allows perfect asepsis and accurate dosage. All that is necessary to do, is to sterilize the syringe by boiling it in distilled water. All parts of the syringe can be taken apart, so that complete sterilization of the

syringe is possible. The syringe is then filled with the solution and gradually poured into the ampuls, filling them with any quantity of the solution desired. The ampuls are sealed in the bunsen flame and then sterilized.

In the *Journal of the American Pharmaceutical Association*, May, 1914, Mr. H. A. B. Dunning, of Baltimore, said that a very simple process in use, in his establishment for making camphorated oil ampuls, was to simply fill the ampul by using the hypodermic syringe, seal the ampuls and sterilize them.

The only possible objection to this method may be that the air in the ordinary dispensing room would be contaminated. This can be overcome by the manufacture of an aseptic hood, consisting of an air-tight box provided with a glass window in the top and a glass side through which light may be admitted, the front containing two arm holes through which the hands of the operator may be thrust. A bunsen burner can be also placed in the hood with a suitable outlet for the gases and in this way the process of filling and sealing can be carried on aseptically.

#### FILLING BY MEANS OF A VACUUM.

The best method for filling ampuls is that in which the use of a vacuum is involved. A rather ingenious method of filling ampuls by vacuum has been tried by Dr. J. Leon Lascoff and found advantageous.

This apparatus has been fully described in a paper on "Camphorated Oils in Ampules," in the *Journal A. Ph. A.*, Vol. 3, 1914, p. 689, in a paper which was presented by the chairman of the section on practical pharmacy and dispensing at the Nashville meeting of the A. Ph. A.

This is a very simple method and can be operated by almost anybody. The principle involved is that by removing the atmospheric pressure of fifteen pounds to the square inch, the liquid will rise in the ampuls to the height of the air pressure plus the pressure exerted by the weight of the solution.

The quantity of liquid that the ampuls contained has been measured and each ampul has been found to contain exactly 2 cc., which in the case of a bichloride of mercury solution, represented seven and a half grains of bichloride of mercury.

Camphorated oil ampuls have been filled in the same manner.

There are many other devices used by different people which work practically under the same principles involved above and therefore need but mentioning of the makes. An apparatus used by Fairchild Bros. & Foster, also the Eury apparatus described by Pegurier and the apparatus described by Spindler in the *Pharmazeutische Zeitung* for 1908, made by Aner, of Zurich, all work by vacuum and work by principles similar to that described above.

The above described apparatus is probably the most convenient and satisfactory method of filling ampuls, also inexpensive to construct and easy to sterilize and can be used not only on a small scale, but also on a large scale, for by adding more glass containers you can increase the filling so much more. Its use is well within the limits of any enterprising pharmacist.

#### TO TEST THE SEALING.

In sealing the point of the ampul, it is not always easy to make sure that the sealing is perfect. This can be readily tested by boiling the filled ampuls in a solution of methylene blue, one grain to two ounces of water, and allowing the

ampuls to remain there until the solution cools. In case the tubes are imperfectly sealed, the color will show in the contents of the ampuls, after having cooled in the solution.

#### STERILIZATION.

The importance of complete sterilization of ampuls and their contents cannot be too strongly accentuated. Its extreme importance can be seen from the coming Ninth Revision of the United States Pharmacopœia and the Fourth Revision of the National Formulary, which contain a chapter on sterilization and from which the following matter has been in part taken. Much care must be exercised at every stage of the operation of making solutions and filling them to insure complete sterility. The utensils, the solvents and the substances used must be sterilized and protected from contamination.

The term "Sterilization," as employed in the practice of medicine and pharmacy means the destruction or removal of bacteria or their spores and other living organisms. This may be accomplished in various ways, depending upon the nature of the object to be sterilized. A sterile condition can be maintained only as long as the substance or object is kept from contact with air or other media which may carry micro-organisms.

These organisms may be pathological. In this case, it would be very harmful if a solution of this nature would be injected into a sick person. It would undoubtedly create a new sickness but a danger of this kind is not very great compared to a second danger, in that the germs which are not pathological at all, are constantly splitting and changing the dissolved organic compounds contained in the solution. In this case, it is very much more important that the ampuls be sterile, more so than the injecting syringe because the contained liquid remains months and years in contact with the ampuls, whereas it only remains a few minutes in contact with the injecting syringe.

#### GLASS UTENSILS.

These may be sterilized by heating them from 160° to 170° C. for two hours in a hot-air sterilizing oven or in a closed vessel (autoclave) under steam pressure at a temperature of from 115° to 120° C. for fifteen minutes. Heating in a current of steam for thirty minutes, or thoroughly boiling for fifteen minutes in water or an aqueous solution of sodium bicarbonate (1-1000) will kill all non-spore-bearing organisms and some spore-bearing organisms. As the presence of even a minute quantity of alkali is frequently objectionable in glass containers, the process of sterilization should in such instances be preceded by a thorough cleansing of the bottle, ampul or other receptacle with one percent hydrochloric acid, followed by a thorough rinsing with distilled water.

It is also possible to sterilize with an alkali solution but must be followed by a new cleaning with an acid solution.

#### MEDICINAL SOLUTIONS OF SUBSTANCES NOT READILY DECOMPOSED BY HEAT.

Solutions which are not injured by high temperature should be sterilized in a current of steam or in an oven in a closed apparatus (autoclave) by steam under pressure.

Sterilization in a current of steam should not be concluded in less than thirty minutes and the heat should preferably be continued for one hour. An exposure

of from fifteen to twenty minutes is sufficient if the sterilization is carried out in a pressure apparatus at a temperature of from  $115^{\circ}$  to  $120^{\circ}$  C.

#### MEDICINAL SOLUTIONS OF SUBSTANCES READILY DECOMPOSED BY HEAT.

With substances affected by heat there is danger of decomposition at high temperatures and Tyndallization or intermittent sterilization must be resorted to. In these cases the ampuls should be heated to  $60^{\circ}$  C. for half an hour at intervals of twenty-four hours for three or four consecutive days.

#### SUBSTANCES DECOMPOSED BY HEAT.

Hager's *Handbuch der Pharmazeutischen Praxis*, states that solutions of the following substances are liable to decomposition at the boiling-point of water: Atropine, cocaine, hyoscyne, scopolamine, duboisine, physostigmine, atoxyl and ergot solutions. Acid hydrochloride of quinine and urea is also liable to be decomposed.

From the statements of other scientists, chemically pure products of these alkaloids and other compounds can stand a very much higher temperature than  $100^{\circ}$  C. without any decomposition. It is not the object of my thesis to decide these contradictory statements.

It is not to be wondered that some of these questions relative to ampuls are undecided, as ampuls have only been lately introduced and therefore more special research work is needed.

#### ADVANTAGES OF AMPULS.
